VOL. XLI.

JANUARY 1, 1913

NO. 1

Editorial

BEEKEEPERS of Ohio should remember the Ohio State Beekeepers' convention at Columbus, Townsend Hall, Ohio State University, Jan. 14 and 15 next. This promises to be the most largely attended convention we have had for many a year. See Convention Notices elsewhere.

MR. DOOLITTLE, in this issue, says he would prefer to have long-lived bees for honey-gathering, even if they are not quite so numerous, rather than a populous colony of short-lived ones. This is a fruitful field for discussion. Perhaps some others would like to give their experiences.

WARM FALL WEATHER CAUSING BEES TO CONSUME THEIR STORES.

IN our Nov. 1st issue, page 679, we reported the shortage of stores in New York. Since then reports have come in from other parts of the country showing that the unusual amount of warm weather in the fall caused the bees to consume a much larger amount of their stores than they ordinarily do at this period. We predict now that many colonies will die of starvation, whether the coming winter be mild or severe. Don't take any thing for granted. Better make an investigation at the first opportune time, and make sure that there are stores enough.

A CORRECTION.

By mistake we credited the picture of the very fine honey exhibit as shown on page 811 of the December 15th issue to Mr. Myers, manager of the Spokane Interstate Fair, whereas it was sent us originally by Mr. F. W. Van De Mark, of Stillwater, Oklahoma, and represents the exhibit of B. F. Bartholomew at the Oklahoma State Fair for 1912. We do not often make blunders of this kind; but we certainly "put our foot in it" on this occasion.

Mr. Van De Mark's letter was duly received; but the photograph he mentioned was delayed in the mails, and did not reach us until about a week later. It so happened

that, when it did come in, the same mail brought the other photograph from Mr. Myers, and these two happened to be close together with Mr. Myers' letter.

The letter of explanation from Mr. Van De Mark, referring to the engraving on page 811, we give herewith:

I enclose a photo of B. F. Bartholomew's exhibit at the Oklahoma State Fair for 1912, just closed. The design in wax, reading "The Home of the Honeybee," and the companion piece at the other side, showing honey-plant with blossoms and bees flying, are all hand-carved work. Few persons will realize the work it has taken on the part of Mr. Bartholomew and his good wife to put this one thousand pounds of honey in glass, mount the honey-plants, and place the exhibit. All of the honey and wax shown is the product of their own bees, and it represents about one-fifth of their honey crop for the year.

Besides the exhibit shown in the picture, there were four others, nearly as good, which speak well for a new State as a honey-producer.

F. W. VAN DE MARK.

The fault is our own in the above instance; but at the same time we wish that our readers, when sending photographs, would take the precaution to write their address plainly on the back of the photograph itself, for the wrappers are often torn or missing altogether, so that it is sometimes difficult to identify each one. In the course of a year we receive a large number of photographs, of which we can use only a small part, and it is of the greatest importance that the addresses of the senders be plainly marked on the back of each, for many times the same mail brings two or more photographs of a similar subject.

CHARACTER OF MATERIAL USED IN BEGINNERS' NUMBER.

IN this issue, the first of our special numbers for 1913, our readers will observe that we have made no effort to select from the material sent us only such articles as portray the rosier side of beekeeping; in fact, we have selected such articles as bring out the mistakes commonly made by beginners.

Lest any beginner reading these pages should be discouraged at the start, and im-

MAR 11 1914

agine that beekeeping is attended by terrible obstacles, we may say that probably the majority starting with bees, if they make something of a study of one or more textbooks on the subject, the chance for costly mistakes is reduced to a minimum. As we have pointed out on another page, if this were not true there would be few beginners who would not become disgusted and go out of the business at once.

Quite a number of our friends responded too late to our call for material to be used in this beginners' number. It is now becoming necessary for us to have in our hands the manuscript to be used, at least three weeks before date of publication, for our plans have to be laid considerably in advance.

WINTERING DOUBLE-WALLED HIVES IN THE CELLAR.

We are trying the experiment of putting some of our colonies, even though in double-walled hives, in the cellar during the coldest part of the winter. Two days ago we put in 100 colonies, taking those from our apiary that were the weakest and the most likely to suffer when severely cold weather should come on. We expect to keep these in the cellar until about March 1; for the stronger colonies will be left outdoors as usual. A year ago we put in the cellar something like 60 or 75 colonies that were somewhat weak, leaving the strongest ones outdoors. The winter, as every one knows, proved to be an extraordinarily severe one. The colonies in the cellar wintered by all odds the best of any we had. We made up our minds that, if another severe winter like the one we had a year ago should come again, we would put nearly all of the bees in the cellar. Fortunately these cold winters come only about once in thirty years.

As a general rule, fair-sized colonies in our locality winter better out of doors than in; hence we shall continue to winter mainly in double-walled hives. In our locality bees have an opportunity for flight on an average of about three or four times in winter.

THAT WINTER NEST AGAIN; A RAP AT DR. MILLER.

ON page 6 of this issue our correspondent Mr. J. L. Byer takes a rap at Dr. Miller. We are not sure whether the "rap" was intended for Dr. Miller or for us. If for us we will try to parry the blow. Mr. Byer describes a colony that has combs solid with stores without any winter nest; and he offers the implied challenge that this will not die during winter. We are inclined to agree with him, because if a colony (es-

pecially if a strong one) has combs solid with stores by Nov. 7 they will have a sufficient winter nest by the middle of January, or about the time settled cold weather comes on. We do not remember what Dr. Miller may have claimed; but our contention is that every colony of bees, if given an opportunity, will form a winter nest or have one before severe cold sets in. This seems to be in accordance with their natural instinct; for when severe weather comes on it is better for one cluster of bees to be separated by only the thin midribs of the combs than by a solid wall of stores one inch thick. In the former case the cluster is practically homogeneous. In the latter it is broken up by cold slabs of stores one inch thick. They can't warm up these slabs because they project beyond the cluster where it is cold. These cold projections convey the cold back to the cluster. Now, Dr. Miller, it is up to you to give Mr. Byer another jab if you think he needs it.

BEEES TRAIL HONEY-THIEVES.

THE following clipping from the *Saturday Blade*, of Chicago, was called to our attention by one of our subscribers, G. F. Jones, Galax, Va.

STERLING, COL., Oct. 24.—When J. M. Cornelius, a honey-producer near Sterling, awoke the other morning he found that in the night fifteen beehives had been looted of fifty pounds of honey. He followed the dispossessed bees to the home of two brothers, living a mile away. There he found the bees swarming about the house, while the brothers, besieged, had shut the door and windows and were afraid to go out. Cornelius swore out warrants for the arrest of the men. They admitted the theft.

When bees show traces of sentiment the tendency can generally be explained in another way. For instance, recalling the old belief that bees would follow the coffin of their owner to the grave, we know that, in the rare instances where they did so, it was because the odor of the fresh varnish used on the newly made coffin attracted the bees by its resemblance to propolis. And in the above case, while the bees apparently exhibited some of the detective ability of Sherlock Holmes, it is plain that the thieves, not knowing that bees during a time of honey dearth are also keen for robbing, did not take the necessary pains to prevent dropping some honey from the broken combs along the way. The bees, of course, immediately found this, and were busy in carrying it back to their hives.

Bees are truly wonderful creatures, but they get a great deal of credit that does not rightly belong to them. We often hear of their affectionate natures—how they mourn when their owner dies, or how they know the one handling them so that they do not sting him, etc.; but there are enough won-

ders in the life of the busy bee without going so far into the realms of imagination.

ADULTERATION AND MISBRANDING OF FIG AND HONEY CAKES.

For over a year we have been looking over the special leaflets sent out by the United States Department of Agriculture with a view of noticing in these columns any case of adulteration or misbranding, of interest to beekeepers. However, though we have found one or two, foods said to contain honey seem to be seldom adulterated. It is very encouraging that one of the results of the pure-food law, unscrupulous dealers are getting tired of trying to substitute glucose or other cheap sweets for honey.

The last instance that has come under our notice has been that of the adulteration and misbranding of fig and honey cakes. We give here the full history of the case as given in the leaflet, as it serves to illustrate just how Uncle Sam goes at a thing of this kind.

On May 23, 1912, the United States Attorney for the District of New Jersey, acting upon a report of the Secretary of Agriculture, filed in the District Court of the United States for said district an information against A. A. Strohecker, Trenton, N. J., alleging shipment by said defendant, in violation of the Foods and Drugs Act, on August 16, 1911, from the State of New Jersey into the State of New York, of a consignment of the product known as fig and honey cakes which were adulterated and misbranded. The product was labeled: "Fig & Honey 19 S. Lipowicz, Buffalo, N. Y." (Guaranteed stamped on side of box): "U. S. Serial No. 2751. Guaranteed under Food and Drugs Act June 30, 1906."

Analysis of a sample of the product by the Bureau of Chemistry of this Department showed the following results: Reducing sugars as invert before inversion, 39.89 per cent; commercial glucose, 37.91 per cent; polarization direct at 21 degrees C., 58.6; polarization invert at 21 degrees C., 58; polarization invert at 87 degrees C., 61.8; weight, 17.125 pounds; shortage (marked and sold for 19 pounds), 9.87 per cent. Adulteration was alleged in the information for the reason that the product being an article for food contained a substance, to wit, commercial glucose, which had been substituted in part for the product. Misbranding was alleged for the reason that the statement on each of the boxes containing the product, to wit, "Fig & Honey 19," would mislead and deceive the purchaser into the belief that the product consisted of fig and honey cakes, and that the contents of each package weighed 19 pounds, whereas in truth and in fact the product contained a substance, to wit, commercial glucose, which had been substituted in part for said product, the presence of which was not declared upon the label, and had been substituted in part for the genuine article, and the contents of each box weighed less than 19 pounds, to wit, 17 1/8 pounds; and further, in that the statement "Guaranteed under the Food and Drugs Act, June 30, 1906," borne on the package created the impression that the product was guaranteed by the United States to be pure, whereas such was not the fact; and further, in that the product was in package form, and the contents were stated in terms of weight to be 19 pounds, and were not correctly stated on the outside of the package, that is to say, the contents of each of said packages weighed only 17 1/8 pounds and not 19 pounds, as labeled.

On May 27, 1912, the defendant entered a plea of guilty, and the court imposed a fine of \$50.

W. M. HAYS, Acting Secretary of Agriculture.
Washington, D. C., August 13, 1912.

FEEDING COLONIES SLABS OF HARD CANDY OR MOIST SUGAR DURING THE WINTER IN LIEU OF ORDINARY SEALED STORES IN THE COMBS.

ELSEWHERE in this department reference is made to the fact that the beautiful fall weather we have been having throughout the northern States, and the comparatively mild winter weather, will have a tendency to cause the bees to use up their stores more rapidly than they otherwise would. In some of our own apiaries we find colonies a little lighter than we feel is safe. We are making up a hundred slabs of hard candy. The hot candy when "done enough" is poured into paper pie-dishes, such as one can purchase at any of the groceries for 40 to 50 cts. a hundred. When cold, these pie-dishes will be inverted and placed directly over the clusters that appear to have an insufficient supply of stores.

Mr. A. C. Miller recently made the statement that coffee A sugar (a moist sugar) can be given to the bees direct. The advantage of it is that it is ready without any special preparation. We have never tried it, but see no reason why it should not be an excellent food. Two or three cross-cleats laid on top of a dish of it will provide an empty space between the cushion and the dish of sugar for a clustering space. The recipe for making hard candy for bees is as follows:

HARD CANDY FOR WINTER AND SPRING FEEDING: HOW TO MAKE IT.

Into a dish of hot water on the stove slowly pour an equal amount of sugar, stirring constantly. Make sure that the sugar is all dissolved before boiling commences. If this precaution is not observed, some of the undissolved sugar is likely to burn, injuring the flavor of the candy and almost surely causing trouble with the bees later. If you have a candy thermometer, watch the temperature, and do not let it go above 275 to 280 degrees. Test frequently by dropping a very little of the syrup into cold water (about 50 to 55 degrees F.). When the boiling has continued long enough the drop of candy, when cooled in the water, should be hard and brittle when taken out; but when placed in the mouth it should soften slightly, so that it is tough. When this time has arrived, pour the syrup immediately.

The color of the candy when cold should be about that of light basswood honey. If it is darkened very much it is scorched and unfit for the bees. To prevent the scorching, reduce the fire toward the last so that the syrup will boil but slowly.

When the candy is first made, it is hard and glassy, and perfectly transparent; but after it stands for a little time it becomes somewhat watery and crystalline; but this is all the better so far as the bees are concerned, for they are enabled to take it more easily.

In regard to hard candy we may say that A. I. Root, years ago, wintered a number of his colonies on it when the bees had nothing but dry combs. We apprehend there will be a good many of our subscribers who, if they will look through their colonies, will find some that are so low that there will be danger of their starving before spring unless fed candy or sugar.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

LIGHT in cellar works in Marengo just as in Borodino, p. 795. As a postscript it might be added that, when bees are in best condition, they will stand a good deal of light; if in bad condition, light is bad.

A GOOD strain of Italians will not lay above the brood-nest, p. 798. May be not, Major Shallard, in Australia, where every thing stands on its head; but in this country the better the queen the more likely to lay above if crowded below.

PFARRER STRAEULI thus treats a swarm: He puts two frames of foundation in the center of the brood-chamber; places on it an excluder, and over this a story with empty combs and some honey, into which he puts the swarm. In no case has the swarm reissued.—*Deutsche Bzcht.*

G. M. DOOLITTLE, I had a good laugh over your trousers standing alone starched with honey, p. 795. I dislike honey on my hands exceedingly; but if I had no water, before using my trousers I'd scour the honey off my hands with earth. "Dirty?" Well, however it may look, soil does not feel so dirty as honey.

BEES should have a larger entrance in winter than in summer, p. 799. That depends, friend Johnson. In this region, bees can hardly have too large an entrance in hot weather. Same in winter, if cellared. But outdoors they would hardly stand in winter to have so large an entrance as my bees have in summer.

CONTRACTING the brood-chamber for winter is advocated because it makes less room for the bees to keep warm in winter. The editor of *Deutsche Bzcht.* says, p. 143, that nothing could be more absurd, since for best wintering the bees must cluster in a sphere, and in too small a chamber there is not room for this. [The editor of *Deutsche Bienenzeitung* is evidently laboring under a misapprehension as to the amount of contraction that is ordinarily practiced in this country. No full colony is ever contracted down to less than five or six frames wide. Such space would give a strong colony all the clustering room it could possibly require. In fact, we have seen powerful colonies contract into a ball during cold weather nearly as small as a doubled fist. Even a three-frame space would accommodate such a cluster, and of course a five or six frame space would be ample.—Ed.]

YOU fellows who have never had any but modern extractors don't know how blest you are. In bygone years, when I produced extracted honey, I had a Peabody ex-

tractor, the pioneer extractor, with can and all revolving. This year, by means of a certain editor who is urging the production of comb honey, I got an up-to-date four-frame extractor, too late for any thing else except to extract a lot of unfinished sections; but, oh the delight it was to extract them! Before the extractor came I had studied just how I would manage in lifting and reversing the frames to have as little drip as possible, for the most unpleasant thing in former years had been the messy drip when frames were lifted out. To my surprise, when I now lifted out the frames there was no drip! I could hardly believe my eyes. And the delightful ease of turning the crank, compared with the former stooping over to revolve the whole machine! I can hardly wait to use that extractor next year, unless the good Lord has something better for me to do before that time. [We hope the good Lord will spare you the pleasure of trying out a modern equipment for taking extracted honey.—Ed.]

JOS. KOCH, *Schweiz. Bztg.*, 310, reports a queen, born in the early summer of 1906, still vigorous and doing good work in 1912. He is sure there can be no mistake as to her age, for she was marked red, and he has marked no queen since with that color. She is of the "Nigra" stock, and was sent to a mating station for pure fertilization. [This is a very remarkable instance of longevity. Had not Mr. Koch marked the queen red we should have said he was surely mistaken. The ordinary supersedure takes place so quietly that in most cases the apiarist never gets any knowledge of it; and when he does see the new queen mother, she often looks so much like the old one that she passes for her.]

But we do not know any way of marking a queen red so that the coloring would not come off in the lapse of six years. If Mr. Koch or anybody else can tell us how to do this with some coloring matter that will not be injurious, he will be conferring a favor on beekeepers generally. As a general rule, however, queens are distinguished by the manner of clipping their wings, either on the left or right side, and by angle cuts. For example, a square-off cut on the left side could indicate 1912; and an angle cut (one each way) could be made to indicate 1913 and 1914. Similar markings on the right side could represent three years more, which certainly would be long enough for at least 99 per cent of all queens.—Ed.]

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

Owing to the demand for space, I will for the present at least discontinue the writing of my summer trip. I find many things of which I wish to write that will be of more interest to my readers, though there is much yet to be said of conditions and beekeepers as I found them on my trip that will be given when the time seems opportune. * * *

LIGHT-AMBER SAGE (?)

In market quotations, Nov. 15, Hamilton & Menderson, of Los Angeles, quote "Light-amber sage." It is my opinion that this is stretching a point. If a producer attempted to sell light amber to this firm as sage they would no doubt fail, and properly so, for there is no such grade in sage honey, and no one knows it better than Hamilton & Menderson. The world produces no better honey than the true sage, which, in its purity, is *white*; but when containing a quantity of other kinds sufficient to put it in the light-amber class it should no longer be called sage.

Any attempt to lower the reputation of sage honey by selling other kinds as "light-amber sage" should be resented by those who take pride in producing the true article, and by those who expect to obtain a fancy price on the merits of its color and quality as well as its world-wide reputation. * * *

SMALL ENTRANCES ALLOW MORE BEES TO WORK IN THE FIELD.

Dr. Miller, Nov. 1, p. 682, I believe the preference of bees for small entrances proves they are best for me, for the reason that what is best for them is best for me. The present agitation for large entrances I believe is not based on sufficient advantages to offset the disadvantages. There are several conditions to be taken into consideration in the discussion of this question. The first object should be to ascertain which will secure the greatest economy in hive service of the bee. The larger the entrance, the greater the number of bees required to guard it; and the ability of the bees to preserve their own heat is much reduced, requiring a greater number in the cluster on the combs for that purpose, thus again reducing the field force which would otherwise be available. These are two good reasons why a small entrance is preferable to a large one, and I believe them sufficient in themselves, though there are others well worth attention. I will admit that a hive booming full of bees can preserve sufficient warmth, regardless of a very large entrance, to build

up rapidly in the spring; but it is accomplished because there are sufficient bees to fill the outer edges of the space between the combs, thus keeping out the cold air with sheer bee force.

Supposing, however, we reduce the entrance to the actual size needed to allow free entrance and exit. In that case there will be a thinning of bees in those spaces, and a much greater force ready to take up the duties of the field.

In the spring of each year, when invoicing my stock of bees and ascertaining their condition, I often find it desirable to transfer a very small colony to a five-frame hive, because in this size of hive they are able to protect themselves better with fewer bees, and to preserve all the warmth they produce, thus enabling the queen to lay over a greater area of comb space than could possibly be kept warm in a ten-frame hive, especially with a large entrance. I am told that a large entrance will prevent or at least delay swarming. True, simply because it not only requires a greater number of bees to preserve the heat of the hive, but a greater number must remain for that duty when the swarm issues, thus requiring a longer period of breeding to reach the necessary strength, and a slower process because they are not able to protect their brood over so large an area where the entrance is allowing the admission of such a quantity of cold air.

Here is also the secret of an eight-frame hive for comb honey. Warmth is more easily preserved, and, in consequence, breeding is more rapid, thus filling the hive much sooner, enabling the bees to pass on up to the super, and there again to develop a sufficient amount of heat to make waxworking practical.

It is well known that bees generate much heat when evaporating nectar for extracting colonies. I have often found it desirable, when nectar was coming in freely, to increase the amount of comb space rather than entrance space. In very hot weather there may be a period when it would be desirable to give more ventilation; but in this climate there are indeed very few nights when they do not find it more comfortable in the hive, out of the cold air.

While we are furnishing the habitation, let us do so with an eye single to efficiency as well as economy in hive service, or else not blame the bees for doing some unavoidable loafing about the hive in order to protect their own welfare.

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

FLAVOR VS. COLOR.

Regarding the matter of choice in taste of honey being one of color or flavor I can agree with Dr. Miller that, if dark honey tasted all right, more would like it. White honey is preferred by the majority as a matter of taste, and yet taste can be cultivated to a certain extent. Who ever liked his first olive? And yet many, including the writer, are very fond of them. In our home at the present we have splendid honey of both basswood and clover; yet for a change we are using once in a while some buckwheat granulated honey of a very smooth texture. Formerly we could eat none of it at all; but we have learned to like the taste. Yet as a "stayer" we all like the white honey best, and I suppose this will be the case for all time with the majority, no matter how much we may boom our buckwheat.

* * *

THE ONTARIO CONVENTION.

The Ontario Beekeepers' convention, held in Toronto Nov. 13, 14, and 15, was a success in the matter of attendance, interest, and good fellowship, and in all of these respects it possibly eclipsed all past meetings of the association. A number of our cousins from "over the line" graced the meeting with their attendance—something that was appreciated very much indeed by us Canucks, and we hope that they all enjoyed their short sojourn with us. In some future issue I hope to give some of the best thoughts of the meeting, after I have had time to digest somewhat the great amount of good things received while there. Officers for next season are practically the same as for last year, with the exception that Mr. Pettit assumes full responsibility as Secretary instead of Mr. Hodgetts, who was relieved on account of having so much work along other lines. Mr. Denis Nolan, of Newton Robinson, is again President. All communications in connection with the association work should be sent to Morley Pettit, O. A. C., Guelph, Ont.

* * *

On Wednesday and Thursday, Nov. 21 and 22, the bees had a splendid flight; and on Friday, the 23d, those at the east yard, 200 miles from home, were all put into the caves at that place. Conditions have been thus ideal for cellar wintering in so far as the *start* in the game is concerned; and with a normal season from now on, the bees wintering inside should come through in good order. At the home apiaries, all the bees had a good flight on the days mention-

ed; and since then up to the present time, Dec. 5, we have had no cold weather to speak of. To-day Mrs. Byer brought in a splendid bunch of pansies; so readers of GLEANINGS may know that we have had a very mild fall here in Ontario.

I might say that, just two days after the bees at the east yard were put inside, about two feet of snow fell. Certainly these bees went just at the right time. Here at home we had only enough snow to cover the ground, and it soon went away. As the weather has been quite mild, no doubt the most of the snow has disappeared out east too; but for all that, if the bees had been caught in a big snowfall the hives would have been in bad condition to carry inside.

* * *

With no desire to start a controversy over a matter that has been pretty well thrashed out in the past, I can not refrain from telling Dr. Miller of an experiment I am trying. Some time ago our good friend stated that if a colony of bees had *solid* combs of honey with no clustering space except the spaces between the combs, said colony would *die* during a prolonged cold spell. Without taking the trouble to look up the matter referred to, I believe that the doctor will remember the circumstances in connection with the discussion when he made the statement. During the last week in October a very strong colony in a regular Danzenbaker hive was fed all the bees it would take into the brood-nest. I might say that the colony is so strong that it was with difficulty the bees could get in the hive after the supers were taken off; in fact, during the coldest weather we have had yet, the bees are snug in every corner of the hive, although no packing is over them yet, all the covering over the frames being a quilt and roof above. Nov. 7 a feeder was again put on the hive, and they have carried down food until every cell must be filled, as they refuse to take any more, and start to build comb in the opening of the feeder. Now, these frames are spaced but $1\frac{3}{8}$ inches apart; and with solid frames of stores in the middle of November what will the bees do for a "winter nest" during the weeks and weeks of cold zero weather that we are pretty sure to have before spring—the colony being wintered on a summer stand, packed in a rough case? Will they die? If the writer is alive next spring, he will report, and in the meantime he will lose no sleep over the fate of that abused colony.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

Brother A. C. Miller, let's have a game of chess with your apiary-record system on page 666, Oct. 15. The ordinary beekeeper with 300 colonies or more will not have the patience to master your method. First you will have to educate him to feel the need of a book-record system; then you will have to give him a thorough course in hieroglyphics. You have laid plans for a 200-colony apiary, and I doubt whether a beeman can be prevailed upon to use it if he has that many colonies.

* * *

LESS ALFALFA BEING GROWN.

With the gradual development of the West from a stock-growing, cattle-feeding country to, a general farming and fruit-growing section, less alfalfa is being grown. Alfalfa is being plowed up to make place for sugar beets, potatoes, onions, and apple and peach orchards. With this development comes a closer and more intensive cultivation. The fence-corners and ditch-banks are kept free from sweet clover, and the roadsides are pastured by the farmers' cattle. Dandelions, sunflowers, and the resinweed produce very inferior honey, and the bees store large quantities of these honeys when the range for alfalfa and sweet clover is limited. These things account for the poorer quality and smaller quantity of honey produced in some of the regions of the West.

* * *

AFFILIATION OF BEEKEEPERS' ASSOCIATIONS.

The local and county association has a work to do that the State association can not do. The latter has work that neither the local nor the National Association can do. The National has work to do that neither the local nor the State associations can do. The problem before the beekeepers is, how to get all local, State, and national associations affiliated where each will help and be an aid to the other. If being affiliated with a State association draws strength from the local association, success is not permanent, and either the local goes down or the local withdraws from the larger association. At the present time there are three local associations in Colorado, none of which are affiliated with the State association. Several members in each local are members of the State association, and that is as far as it goes. The local association does not seem to be able to survive unless there is some financial gain to be had. This financial gain is secured through ordering

supplies in a body. Shipping honey together is also done on a limited basis. The fraternal association solely is going; and if local, State, and the national can be united on a business basis with the fraternal part on the side we can expect a larger degree of success all along the line.

* * *

STARTING ON A LARGE SCALE.

The beginner can start more varied trains of thought on beekeeping than a seasoned veteran would think of in several days. The veteran has mastered and forgotten so many things that the beginner asks about that a writer can not do better than to talk with some beginner in order to get original subjects for his writing.

The proverbial advice to beginners is, to start with a very few colonies and build up. That is all very well; but I have seen the beginners start with a hundred colonies, and make a success from the start. It depends on the man. A farmer or other rural worker who has had experience with farming, gardening, fruit-growing, etc., and has made a success at these, can begin with bees and make a success without the long tedious building-up from one or two hives. The trouble with the beginner is that he is so enthusiastic that he goes through his one or two hives every day or two, and worries them to death, or at least he secures only a partial crop. The man with more colonies will not have the time to open his hives so often, and will confine his operations more to preparing supers, arranging the apiary, taking honey, handling increase, etc. The beginner will probably have a lot of experience hiving swarms the first year; and when he runs up against difficulties he will seek out the experienced man for advice or will hunt up the points desired in the bee-journals or bee-books. I would disabuse the beginner of the thought that, because a man is making his sole living from bees, he is a master beekeeper. His success may be largely due to a favorable location. I have known men who have done well with bees for a term of years, and then when foul brood or poor seasons came they lost out completely. Beekeeping is pleasant work, and should yield as satisfactory returns as any other rural pursuit.

The field is open, and much money is not required, and I hope that we may have a good number of eager beginners added to our ranks during the coming year.

Conversations with Doolittle

At Borodine, New York.

PROLIFICNESS OF QUEENS VS. LONGEVITY OF BEES.

"As I am a comparative beginner, and much interested in the improvement of bees, will you not write something for your department regarding prolific queens, for my queens are disappointing in this respect?"

"I am aware that a hive full of brood at the right time of the year is a sight that entrances any apiarist; therefore prolificness in queens is something almost invariably desired, and that especially by beginners. I remember well when I used to read with wide-open eyes and mouth about certain queens being able to keep ten Langstroth frames full of brood for weeks and even months at a time. As I had few, if any, of which this could be said, I often thought the bees I had were not what they should be, which led me to buy queens of those claiming to have the most prolific strain in the world, but they were not much better.

"At our bee conventions a third of a century ago, in summing up the desirable qualities of any race of bees, or of a queen, prolificness was the quality almost always put at the head of the list. But some of us have changed our minds considerably since then, and consider that there are other points of more importance than great prolificness. Some have even asserted that great prolificness is often at the expense of other desirable qualities. There are few beekeepers who have not had it impressed upon them that it is not always the most prolific colony that gives the most surplus.

"I now consider quality in bees more to be desired than prolificness, for the more bees of poor quality one has the worse off he is. Some of our older heads are prone to stick to the ideas of half a century ago; but there are few classes of men more anxious to adopt progressive ideas and methods than are apiarists. But, no matter what our ideas, the fact remains that the colony of bees which gathers the largest surplus during each season, and consumes the smallest amount of this surplus in maintaining a good healthy existence between and after the honey-flows, is the most profitable one, and therefore the one to breed from. And in order to set to work intelligently for the improvement of stock to the highest standard of excellence, it is necessary to know the qualities which stand first in the make-up for first-class honey-gatherers.

"About twenty years ago there were daughters of a certain queen in my apiary whose bees forged ahead of the rest of the

colonies; but repeated examinations showed that these queens were hardly up to the average as brood-producers. In fact, with the exception of one or two, six Langstroth frames were the highest amount of brood any of these gave. And I began to study on this to find out the reason. I got up early in the morning, mistrusting that I would find them out at work while the colonies with a greater amount of brood and bees were asleep; but they did not get out earlier in the morning, nor seem to do a rushing business at any time, but just plodded away with a steady pull all day, with no seeming advantage along this line above the other colonies in the apiary; and this, not for one week, one month, nor one year; but a continual keeping ahead as regards the surplus produced, with fewer bees and no longer hours of work. Six frames of their brood seemed to give just as good results as eight or nine of other queens. This seemed unaccountable to me till one August a change of queens was necessary in one of the hives. As the new queen gave bees of a somewhat different color, and change solved the mystery, for I found many bees from the original queen busily at work bringing in honey clear up to the last of the following June. The longevity of these bees saved the labor, the honey, and the pollen necessary to rear two or three extra frames of brood reared by the more prolific queens, and this saving served to lengthen their time of service as field workers. Then I found that for out-apiary work, the small amount of brood for the size of the hive (I use a ten-frame Langstroth hive at the out-apiary) tended to discourage swarming. This was a gain of much value. Then less heat was required to rear a smaller amount of brood in early spring, and all tended toward longer life, which longer life gave the increased yield of surplus, and at less expense of bee force.

"After having found out some of the qualities, at least, which made for first-class honey-gatherers, I then set about working along the line of getting these queens in a way of putting the maximum number of bees on the stage of action at the time of the honey-flow or flows as they came in this locality, and only a sufficient number at all other times for a good healthy existence, as I have told the readers of the bee papers once or twice before. And this last is not by any means the least, for herein lies one of the greatest gains possible to make along the line of the improvement of any race."

General Correspondence

EXPERIENCES AND MISTAKES OF BEGINNERS

BY J. L. BYER

In glancing over the subjects outlined on the inside of the front cover of *GLEANINGS* for Dec. 1, the one in connection with mistakes and experiences of beginners struck me most forcibly. While not a beginner any more in the strict sense of the word (yet after all it seems but a short time since I was struggling to get enough bees to make a living) there are as yet no *veteran* feelings in my own mind; and as for experiences, naturally I have had the usual amount that come to the lot of anybody who starts in any business with no capital and with a family to support.

My first bees were bought on credit, but were not taken on those terms until earnestly requested to do so by the friend who had them for sale. My note for 12 months was given, and the bees were moved in November. They were in single-walled hives when bought, and after that date I transferred them into packed hives I had made, lifting the combs out two by two from one hive to another. Any one familiar with our climate knows that transferring bees in November here in Ontario is not good policy, but in this case luck favored me, and they wintered all right. The crop was good that season, and I paid for the bees, and had a bit of cash left. This was, of course, "experience;" but I am at a loss to say whether I would consider it a "mistake" for a person situated as I was to go in debt for bees or not. Certainly it is at best a risky way of starting. Just here I might state the promise of the man, that, in case I could not meet the note when due, he would not sue me any way. While he was perfectly honest in this assurance, I suspect it would have done him little good to take such a step, as it "is hard to get blood out of a turnip," as the old saying goes, and so just as useless to try to get money from a man who has none.

In looking back over the past few years I note many things that have been done that seem now to have been "mistakes," and yet under the circumstances I am led to wonder whether some of these "mistakes" could have been avoided. With only a few bees, it was impossible to think of making a living for the family, and of course the thing that came to my mind as a solution of the problem was in line with the advice of our departed friend Hutchinson, "Keep more bees."

With practically no capital, it was im-

possible for me to discriminate in the matter of hives, etc.; and, as a result, bees were bought anywhere I could get them, and in all kind of hives. This proceeding naturally gave and is giving me lots of "experience," and to the minds of most men it will no doubt be classed as a "mistake;" yet if placed in the same position again, I no doubt would do just as I did before, with some modifications learned by hard experience of the past. It certainly is, under ordinary conditions, a great mistake to have a number of different sizes of hives; but under exceptional conditions there is license for almost any thing, and the position I was in called for radical methods if I was going to keep on top.

During the time I was buying up bees here and there, many more colonies were kept by farmers than is now the case, and I soon learned that I could profitably buy first swarms, when they were offered to me, at about \$1.00 each. Many a night have I driven six or eight miles after a hard day's work on the farm, in order to bring home two or three colonies from some man to whom I had taken empty hives earlier in the season. I remember in particular a farmer friend who complained bitterly because his bees threw out so many after-swarms; and to help him out I told him to hive the first swarms on the old stands *a la* Heddon, and after six days move the old stock to a distant corner of the apiary. After a week or two he sent word to me to come and get the swarms he had hived for me; and, imagine my surprise to find the said swarms with all foundation drawn out, and the bees hanging outside the entrance in great clusters! He remarked, "I fixed the beggars this time so that they would not swarm the second time." He had followed my advice in the matter all right; but little did I suspect that I was going to profit by it at the time. As the man in question seldom tried to get any honey from his bees, my conscience did not bother me any, and I took the bees home, getting about 100 pounds of clover honey from each. This little episode gave me "experience" all right; and even up to the present I can not admit that there was any mistake so far as I was concerned.

About this time I contracted a disease that I am afraid has become chronic—namely, a desire to talk in the journals as well as face to face with people. Accordingly an article was sent to *GLEANINGS* in which I told of the advantages of big hives, incidentally mixing in some other twaddle as

well. Being more bashful than at the present time, my name was signed "Jack Canuck, Hoodstown, Ont." Hoodstown was the name of a postoffice in the north that I visited once, but which I knew was closed up at the time of writing. I was rather surprised to see the article printed, and to note that friend E. R. had appended a nice friendly footnote to the same. This made me bolder, and I immediately sent another article and received the surprise of my life when I got a letter from the publishers with a "credit note" enclosed. Doubtless poor Jack Canuck, of Hoodstown, had received a "credit note" also, and this on my part was a "mistake," and I have never since signed any name but my own, for fear some "credit note" might go astray.

To beginners in beekeeping, let me say that the habit of getting mixed up in the journals is very hard to "get cured off" when once contracted; so my advice is, never start it if you want to be saved a lot of work and the trouble of answering a pile of correspondence. Of course, if you have no objections to the things mentioned, go ahead, and probably you will get a lot of fun for your trouble, to say nothing of the bit of "pin money" that comes with it as a consoling reward.

The question will naturally be asked how foul brood was avoided when I bought bees in so many places. I was fully alive to the danger of this pest; and as I had never seen a case of foul brood I got in touch with friend McEvoy, and he sent me word when he was going to visit an infected apiary about 25 miles from my home. I made the journey of some 50 miles all told, and I think it paid me well, for from that time it has been no trouble for me to tell the disease at a glance—a cell of foul brood looking much like a blot of ink on a sheet of paper, if I dare make such a comparison. American foul brood has distinctive characteristics that can not be mistaken to the practiced eye, and I have often wondered at hearing some say that they could not learn to detect it. One thing is certain: The beginner to-day must learn to know bee diseases if he wishes to stay on the job. The trip I have mentioned was worth much to me, for shortly after that time I bought some bees at a sale and found they were diseased. They were promptly cleaned up; and although I have twice since that time bought it again (once knowingly, so as to avoid the bees being scattered all over the country), never have I had any difficulty in cleaning up; and at the present, in so far as I know, there is none in any of my yards.

After getting about 100 colonies in two yards, I had rather severe winter losses, and I came to the conclusion that this matter had to be solved if I wished to make a living out of bees. Diagnosing the dead colonies in the spring, I always found that the bees had either starved outright or else part of the cluster had run out of stores, the rest of the bees usually perishing later on in the spring from dysentery. I used to read about giving 25 or 30 pounds of stores for wintering; but gradually I learned that, for outdoor wintering, at least in our climate, it is necessary to have more than that amount, and that, generally speaking, it is a mistake to have a lot of unsealed pollen in the center of the brood-nest for the bees to cluster on.

I visited some of our most successful winterers, and came away with the idea that their success was not due to any particular kind of hive, packing, location, or other minor factors, but simply because they gave their bees abundance of good stores. After a number of years' "experience" with many "mistakes" made in the mean time, I have never changed that view, and upon that main principle rests the success of good wintering, all other factors mentioned such as hives, packing, etc., being mere incidentals. To the beginner I would urge due attention to this matter, especially if living in a cold climate, otherwise he will not only have unpleasant and unprofitable "experience," but in the end will have to pronounce his beekeeping career as a huge "mistake."

When taking a retrospective view like this, many events come to one's mind which, while interesting to the parties directly concerned, are not so to readers in general, so I will close this random article, but I wish to add that, with all my varied ups and downs in the struggle to make a living from bees, never once have I regretted my choice of a life vocation; and while we have not made so much money, the friends and associations formed during the time our work has been going on are valued far above monetary considerations. The help received so ungrudgingly from many friends in the past in the way of advice, etc., is remembered with pleasure, and it is always a source of pleasure for me to help others struggling along, when it is in my power to do so. Never once do I recall asking for any favor from a beekeeper but that it was granted in a spirit showing that the help was given freely. Last, but not least, the best help I have had in the matter of attaining any little success in life that has come our way is the company of a *good wife*; and let me say that every beginner

needs this "experience," otherwise his life is apt to be pretty much a series of big "mistakes."

Mount Joy, Ontario, Canada.

AN EXPERIENCE WITH BLACK BEES

A Fight with Hornets

BY OSCAR L. GOSSET

The latter part of June I found a small swarm of black bees hanging on a bush in the pasture. As I did not have a hive I made a box of nice clean lumber. The boards were 12 inches wide, and I cut them so as to make a box 12 inches wide, 12 in height, and 24 long. I hived the bees; and, although it was a small swarm, the colony went right to work. I left the bees under the bush where I had hived them, for about one week.

It happened that the hive was placed near a ditch; and in case of a hard storm the water might have risen and washed away the hive.

One evening, about ten o'clock, there were indications of an approaching thunder shower. The bees were my first thought. As it was so late in the evening, I knew that they would all be in the hive, and I thought it would be a good time to move them near the house, a distance of about sixty rods from where the hive was then located. I set the hive down not far from the house, where I could watch the bees. A day or two after I had moved them I found very few bees in the hive; so I went back to the pasture to the spot where the hive had been, and found most of the swarm clustered on a branch of the same bush on which I had first found them.

I returned home, made another small box, went back, and shook the bees from the branch in front of the box, and they all went in. That evening after sunset I brought the box with the bees to the house and emptied them in front of the first box. They all went in; and as they had made quite a large piece of comb in the first box I thought they would soon stay there. The next day I discovered that a few of the bees had returned to the bush in the pasture. I managed to get them into the box, and took them home in the evening, emptying them in front of the hive as before. The next day the bees were working well.

I noticed, about the middle of August, that the colony was not increasing very much. A few drones had hatched. I also noticed that the bees did not have a very large amount of honey, so I ordered a

Boardman feeder and proceeded to feed them. They had carried in about one quart of the syrup from the jar when one day I noticed some black hornets near the entrance, fighting the bees. The bees were out on guard as if attacked by robbers. I killed about a dozen of the hornets; and as there were no more in sight I stood watching the hive. A bee came out with a young bee which seemed to be dead, for it showed no life when I picked it up from the entrance where the bee dropped it. It looked as though it had been cut from the cell before time for it to come out, as its wings were shriveled.

A day or two after this I took a look at my bees. As I approached the hive I saw no bees flying; so I raised the hive, but found only about half a dozen dead bees lying on the bottom-board, and about half a dozen hornets sucking the comb in the hive. The honey and syrup that I had fed the bees had been all carried away, for the combs were almost dry. There was a little brood in one of the combs. Now, did those hornets chase the bees out of the hive and rob them? or did a strong colony of bees rob my bees? There were no other bees nearer than half a mile.

Maiden Rock, Wis., Sept. 24.

[Your principal mistake was in moving the colony after it had once been located and the bees had marked their location. Carrying a hive away in this manner without taking any precaution to make the bees mark their new location will always result in weakening the colony greatly, for the bees will keep attempting to go back to the old location, and many of them will be lost.

Undoubtedly the hornets bothered the bees considerably; but we think the chief trouble was that the colony was so small that the bees became discouraged. They may have left the hive in a body because the conditions were abnormal, or, as you suggest, the bees of some other colony might have completely robbed them out, so that they abandoned the hive because there was practically no honey left.

It is expensive business attempting to nurse a weak colony. We presume that beginners have more trouble because of having their colonies too weak than from any other source.—Ed.]

I raised 100 daughters from a fine breeding queen which I bought last spring. I hope she will live another year. I have 200 colonies, and have handled bees for many years, but they are the first bees I ever saw that wouldn't sting. I handle them without smoke.

Freewater, Ore., Nov. 16.

C. A. McCARTY.

A BEGINNER'S EXPERIENCE

BY B. KEEP

Like so many others, I began beekeeping by chance. My good wife often suggested how nice it would be to have some bees; but after reading "Quinby's New Beekeeping" I could not bring myself to the point of assuming the responsibility and risk. After eleven years on the new place, chance put it upon me, and, presto! shortly I became devoted to bees, and I could not get enough.

A small swarm discovered near the close of a drizzly Sunday in May was the germ; and the trifling knowledge gained years before from Quinby enabled me to get the bees into a small box, and to place it where the colony was to remain. We often talk of that first experience, remembering with amusement the excitement caused by the discovery, and the subsequent hustling for a box, some kind of veil, and a pair of thick winter gloves; then all hands standing at a respectful distance holding breath until "the trick was turned." I would not forget it if I could. So much interest has not been bestowed on any bees since that first swarm. It was a common occurrence to find some member of the family standing or seated near the hive intently watching the bees go and come, and often all were gathered there discussing the mystery of the hive and the possibility of honey from our own bees. I was thoroughly captivated. The responsibility and risk sat far more lightly upon me than I had supposed, and no nightmares with bees in any form troubled my repose.

I determined to learn all that books and periodicals had to offer, and to be as far as possible a scientific beekeeper. To that end I got a copy of the latest A B C and X Y Z, and devoted all spare time and evenings to the reading and rereading of every subject. In fact, I made a study of it. There was a fascination about every thing. Then I branched out into Langstroth, Miller, Alexander, Doolittle, Townsend, and Cowan, and devoured GLEANINGS, the *American Bee Journal*, and *Review*, not to mention all the pamphlets available. By these means I gained views on beekeeping from various points, and began to consider a system for managing my embryo apiary.

But, to return to my story. That first season stands out as including more experiences and a greater variety of ways for the acquiring of bees than ordinarily come to the beginner, even after many seasons. My first was a swarm, the swarm. The next came by purchase (this colony contained a

\$2.50 tested queen, and it has been my very best to the present moment, having given three frames of sealed brood and over 90 pounds of extracted this season. The queen was superseded the second summer). The next was a swarm, caught by my son. The next was a two-frame nucleus from No. 2. The next was chiseled out of a hollow tree in the middle of a hot August day. The next (the sixth and last of that first season) was a cluster of the field bees not captured with the combs and bees from the hollow tree two days before. Owing to inexperience and a strong desire for more bees, these were not united, but both were carried through the winter successfully. The queen having been lost by reason of inexperience, each "swarm" was supplied with a new queen.

Through all that season's campaign each member of the family became initiated by at least one sting, I myself taking no more than four degrees.

That autumn I made jackets of old carpet which were slipped over each hive body and then wrapped with an asphalt roofing felt, which was held closely by string and tacks. That season is recorded as "the worst ever;" but having fed liberally, all came out the following spring in good condition.

The number was increased to ten the second season by divisions and one swarm. That one swarm came out with a virgin queen. Fortunately I was at home, and with the aid of a hose I secured them without trouble. Seven young queens were found running around in the old hive, and many queen-cells in all stages, but no brood and but little stores. One supersedure and a colony queenless in October, together with some experimenting, made up quite a program. That was also a poor season, so there was yet no surplus, and some feeding was required. The same winter arrangement was used, and all came through in good condition.

This spring I began to make the hives over with double walls. They are now all double-walled, six with the old $\frac{7}{8}$ -inch hive-body having a space of about $\frac{5}{8}$ inch. Some were packed with mineral wool and others with sawdust, all having $\frac{3}{8}$ -inch outer walls. Four are regular double-walled with deep slip covers. All have three to five inches of sawdust on top. I use super covers all the year through. All have two-inch rims between the bottom-board and hive body, and eight-inch winter-entrance boards, which were described and illustrated in the Sept. 1st number of GLEANINGS.

By Boulder Creek.—Photo by Wesley Foster. Along the streams the willows, maples, and cottonwoods are the first to gladden the bees with offerings of pollen and honey.

EDUCATION AND THE CAMERA

BY WESLEY FOSTER

[Few have realized that our department editor from Colorado is a picture-lover. He is not a kodak fiend who snaps every thing and yet makes no real pictures, but an enthusiast who sees the beauties of nature with artistic eyes, and who is able, by the aid of his camera, to make permanent what he sees.

We give place to this article here, not so much because it will be a help to beginners in beekeeping, but because it will serve as an introduction to several other beautifully illustrated articles by Mr. Foster, to appear in the near future, that will make beekeeping more intelligible to beginners and more interesting to all.

The cover picture for this issue, "Nature's Own Parking," is the third photograph submitted with this article.—ED.]

If some educational dreamer had arisen twenty years ago and advocated the introduction of picture-taking as a part of the school curriculum he would have been laughed at; but to-day we already have the dark-room along with the laboratories in our modern schools.

The old idea about picture-taking, stereopticon entertainments, and such like, was that they were merely diversions, while now it is recognized that we learn quicker and retain longer what has been absorbed in an atmosphere of pleasure. And in every village, where there are camera "fiends" I hope they will lay the matter of a picture-

making studio before the school board when a new building is to go up or an old one remodeled.

The camera will be an aid to all other studies—the mathematics of correct exposures, the chemistry of development, the botany and geology shown in the pictures, and the cultural development from the study of composition. You can well nigh get an all-round education with your camera.

Nature is the mother of us all; and any means of getting a closer view of her workings should be eagerly seized. The camera will fix the various phases of nature indelibly in the mind, and be a constant source of pleasure to the possessor of the memories of the walks in the fields, together with a pride in the pictures taken.

Awaken the spirit of observation, and the world increases in interest. The weeds by the roadside, with their seed-pods held high above the snow in winter, furnish the birds with their winter food. Stop in your walk and watch them getting their dinner. If your camera is along, take a picture. What kind of birds are they? If you do not know, the work of taking the picture will give an opportunity to note their markings and characteristics, so that, when at home, they can be looked up.

Take a walk through the woods in the

"The Majesty of the Hills."—Photo by Wesley Foster.

fall. There before you is a side hill down which the road winds into the valley and across a bridge over a creek in the valley. From among the trees is disclosed the outline of a house, smoke rising from the chimney.

To the ear comes the dog's bark, and the familiar farmyard sounds of cattle and chickens. There is a picture with road and hillside for a foreground, and the road leading the interest right up to the farmstead; and as the feeling of content wells up within, you will almost instinctively find the spot where you can express the spirit of the scene by eliminating most of the irrelevant things in the landscape. But few things need to be shown — the farmstead and the naked trees with the road and bridge leading up to the house. What is desired is balance in the picture—not all the light or shade on one side or the center of interest placed right in the middle. Have it a little above or below and to one side of the center. What is essential is that you feel the meaning, and the results are sure to be better than if pictures are made hurriedly. The scene is a beautiful one, and you should absorb the impressions along with the film.

The technique of making correctly timed exposures is nearly equal to mathematics for mental drill. The animation of the camerist dispels the thought of drudgery. With a R. R. lens the bulk of my exposures are made in 1-10 second stopped down to 32. I vary this according to the light, and have fair success in getting landscapes. I do not like to take many pictures in the brightest sunlight, preferring some clouds, for softer tones seem to be the result.

An expensive outfit is not necessary. A six-dollar camera taking some of my best pictures was the one that got me interested in taking pictures. A medium-priced camera is the best to start with, and a better outfit may be bought later on.

At first it may pay to take the films or plates to a photographer for developing

"Fools not all dead yet." The section shown in this illustration was folded inside out; and although the corners broke it held together long enough to be put into the super, and then the comb held it together.

and printing. If he is talkative you will soon learn points that will help in doing this work yourself. The catalogs and booklets sent out by the photo-supply dealers will soon give one a good working knowledge if they are studied.

Composition is the whole thing in picture-taking. Some say it is all in the lens; but the best lens will not make a picture out of a piece of landscape if the elements that make up a picture are not brought together in right relations on the film. The cheapest of lenses will make a picture if the limits of the lens are taken into account.

Camera catalogs warn against taking pictures with the lens pointed toward the sun; but by shading the lens from the rays of the sun, atmospheric effects can be obtained that are hard to secure any other way.

"By Boulder Creek" was taken with the camera facing the sun, shading the lens with my hat. The feeling of spring is there; the buds are just opening, and the bees are getting their first pollen. Boulder Creek has not yet begun to rise from the melting snow in the mountains. There is not the detail in the shadows that I should like; but being only an amateur I have not learned how to make a picture more attractive after it has been taken. "Majesty of the Hills"

Colony of bees transferred from the wall of a garage to the hive shown.

shows the mountain forests and the timber line, the peak shown rising to an altitude of about 13,000 feet. A cloud hangs down over one of the peaks. The pine-laden canyon is nearly two miles wide; and as I focus my camera the pine squirrels and bluejays are scolding each other in the trees, while the water-ouzel fishes for bugs and worms in the stream, faintly heard in the canyon's depth. We rejoice that we can keep these memories fresh with the lens and plates of our camera.

Boulder, Colo.

BEEES THAT WORKED IN THE RAIN

BY FRANK S. LOCKE

I am sending a picture of a very remarkable colony of hybrids—at least they appear so to an amateur such as myself. I know that I am working at something a little out of my line; but the study has become so interesting to me that I shall have to be tolerated by those who think me over-enthused.

I am a chauffeur by profession, and an ardent admirer of the A B C and X Y Z of Bee Culture, to say nothing of GLEANINGS. I spend six months of the year in the

country; and during the early part of this summer I was attracted by a swarm of bees which were making the air merry about my garage. I started the motor of a six-cylinder car, making much noise, and was finally rewarded by seeing the mass cluster on a tree near by. I knew absolutely nothing of bees or their habits at the time, but made up my mind to ascertain a few things on the spot myself. I shook the swarm into a box, then transferred them to a hive later. They made a break a few days afterward because I moved them, not knowing any better, and absconded for parts unknown, but my interest did not go with them. I looked at the hive (quite empty now), and found that I had only a small piece of comb, seven frames with starters, and last, but not least, a keen desire to see those little rascals busily engaged again. Therein lies my tale.

You will see in the photograph a window, at the upper left-hand corner of which was the flight-hole of a stray colony that had been there for three years. Lower down, near the entrance to the hive, you will observe an escape which I manufactured from a tobacco-box of tin. A fine spiral spring did the work. Before putting on the escape I nailed screen wire over every available

exit they might find, then cut a small square hole lower down, over which the escape now lies. In two days every bee in the house was using my new hole as an entrance; then I put on the escape, placing my hive in position at the same time. I do not know how the Porter works; but I must say the bees simply fell through this one of mine. They just crowded one another out through this spiral spring flapper I made. Any bee that once crawled into the tin was forced bodily out. I can move the flapper out by blowing on it, but it opens out only. No bee ever crawled back.

Now for the queer part:

Those bees accepted a hive without eggs, bees, or brood. They had foundation starters only. They built comb, filling it with honey. There were no laying workers among them, and no queen, as I ascertained later, before introducing an Italian queen.

They were three weeks without a queen, and simply went crazy with joy when I gave them their new mother. She was of good quality, laying on the second day after coming through the mail. They start at daylight, working like mad, and I can say in all sincerity that, during the past two days, those same bees have been flying at work in a steady rain which has left large puddles everywhere one looks.

The whole business looks queer to me as they come in all wet with their wings spread wide as they walk—no stopping them. I wish I had about 100 colonies of such bees. I'd stop driving automobiles.

San Mateo, Cal., Sept. 7.

BEES BUILDING WORDS IN COMB HONEY

BY I. HOPKINS

In the August 15th issue, page 515, you ask for articles on the method of making the bees build letters in comb. The accompanying photo shows the words "State Apiary" built by the bees we had in the government model apiary, established a few years ago at our international exhibition. The body of the photo is an exhibit of a portion of the honey raised at the model apiary; but owing to the photographer not using a color-screen on his lens the amber-colored honey in the glass jars came out black like ink.

The case over the exhibit contains the words mentioned, in comb honey. The case was nine feet long, and the words occupied a length of nearly eight feet. At each end of the case is a bell glass filled with comb honey, built by the bees also. Each letter

New Zealand Honey Exhibit. The words, "State Apiary," were built by the bees in comb honey.

James Woodzell, Webster Springs, W. Va., and his apiary of 38 colonies. The shade-boards are the covers of winter cases made from coffee-boxes.

was eight inches in height and two inches broad in the stroke.

HOW THE LETTERS WERE ARRANGED.

First of all, I made frames one inch wide out of quarter-inch stuff, similar to brood frames. I then obtained some bare half-inch well-seasoned boards, screwed them together, and cut them to fit the frames. They were then handed over to a man having a fret-saw, to cut out the letters right through the two boards. Each frame afforded space for two letters. The boards were next taken apart, and a sheet of foundation laid between the two boards, and the latter screwed together again. Now, the only places within the frames the bees could build when they were in place was where the letters were cut out on each side of the boards.

HOW TO GET THE LETTERS BUILT OUT QUICKLY

The quicker the letters are built, the better appearance they will have. For this purpose, choose extra strong two or three story colonies, and see that the queen is confined to the brood-chamber with an excluder above the frames. Place a couple of frames of lettering in the center of the top box immediately above the brood-chamber, with one frame of comb between, and remove them directly. The comb in the letters are capped over. The lettering should be done when the honey-flow is fully on. My first attempt was made over thirty years ago.

Auckland, N. Z., Sept. 16.

WINTER CASES MADE OF COFFEE-BOXES

BY JAMES WOODZELL

The picture shows a corner of my apiary of 38 colonies, all of which are in eight-frame dovetailed hives. Grapevines on three sides, and a wood-house and dairy on the other side, give considerable protection from cold winds.

I winter my bees on their summer stands. I take coffee-boxes, such as are used for Lion's or Arbuckle's 100-lb. packages, and cut off the bottoms and tops. Then I cut out three inches from the bottom of one end and nail the piece back in such a way as to make a shelf over the entrance. I set this prepared box over the hive, and thus have about three inches of space on all sides, and nearly as much over the top, which I fill with hay. The tops and bottoms of the boxes make the covers, which are used in the summer for shade-boards as shown in the engraving. I nail four pieces of narrow boards together, making a framework on which are nailed the top-boards of the coffee-box. Then I cover the whole thing with cheap felt roofing. These covers telescope over the winter cases. By using these cases I have had very little winter loss.

My hive-stands are made by nailing ten-inch legs on a square framework made of four narrow boards, and covering this with one-inch boards for a top.

For my surplus honey I use shallow extracting supers, and cut the honey from the frames in four pieces, weighing approximately one pound each. I have no trouble in disposing of all of it at 20 cts. per pound.

Webster Springs, W. Va.

GRANDPA NICKEL

BY MRS. MARY ROBISON

I am sending you a picture of grandpa Nickel, a dear lover of GLEANINGS. He is very much interested in all of its articles, especially in the Temperance and Our Homes departments. He is a retired farmer, and keeps a small apiary for pastime and pleasure. His honey, of which he always has a good supply, he divides among his children, grandchildren, and friends. He does not know I am sending his picture, and I want to surprise him. Grandpa Nickel is my father.

EXPERIENCES OF A FOUL-BROOD INSPECTOR

Different Types of Beekeepers Met

BY J. E. CRANE

Continued from page 815, Dec. 15.

There is reason to believe that there are some persons who are not fond of seeing an inspector. One man told me that last spring the cattle commissioner condemned and killed most of his cows, and now I had come to kill his bees, and he seemed to feel as though his lot were a hard one.

A good lady was afraid the inspector would open her hives and set the bees to robbing (as no honey was coming in), make them cross, and that they would sting the domestic animals and even poultry, causing any amount of mischief. She reasoned well, only she did not know the inspector. (One man told me that last year he lost 75 turkeys by the bees stinging them to death. I can not vouch for the truth of his story; but I think there may be some truth in it, as I believe his bees were the crossdest I have ever seen.) But there was no disease among this woman's bees. On the contrary, I found that her hives had had the nicest care, and her surplus combs were the finest I had seen anywhere. I have sometimes thought that beekeeping is not adapted to women, nor women adapted to keeping bees; but since I have seen the success of this woman, and of others whom I might mention, I have decided that it might be well to revise my opinion on the subject.

One woman went with her husband to look over the bees on a hot summer day. He had on a thick coat, gloves, and veil to protect him from stings, while she walked around fearlessly with bare hands and arms.

Still another woman, the mother of five small children, I found helping her grandfather, who was eighty-three years of age, and nearly blind, caring for a large yard of bees. With me she looked through the entire yard to find any diseased colonies. She told me she was in perfect health, and enjoyed the outdoor life.

An inspector has many opportunities to receive as well as to give instructions. In going around among all sorts of beekeepers he finds many persons who excite his pity or sympathy. One of these, an old man with a farm and a few bees, appeared feeble, and had but one hand. I have seen many one-armed people, but never before one that appealed to me as he did. How could he care for his bees with but one hand? I often find myself wishing I had three when I am working with them.

Beekeeping as taught in some of the rural schools of England.

One woman whose bees I went to inspect lived in an old house. Her clothes were in rags, and were thrown carelessly upon her person. Her house was in the utmost disorder. She seemed to think I had some sinister motive in asking her name, and would not tell me. I have since wondered if some Christian woman could not go to her, carrying some of the comforts of life, and take her hand and tell her that the good Lord loves and cares for her, and bring some light, cheer, and hope into her desolate abode.

And yet another. His neighbor carried me over to see him, and told me on the way that he was somewhat cranky. On reaching the place he introduced me to him. I offered him my hand, which he refused, saying, as he drew back, "I don't know you, sir." As I looked into his face and saw the wild, strange expression, I recognized that he was insane. Yet he was living alone, caring for himself. He had a good garden, and one of the largest yards of bees in the town. I suggested looking at his bees. He told me it was unnecessary. He knew all about bees, and said that they had no disease. Nothing I could say would convince him; but I admired his large patch of fragrant onions without a weed; his thrifty turnips, and his potatoes so free from beetles. He slowly relaxed; and while his neighbor engaged him in conversation on the value of different varieties of potatoes I managed to look into several of his weaker colonies where disease would be most likely to show itself if present. When I was ready to leave he bade me good-by with a hearty hand-shake, and asked me to come again. How sad to see the marvelous mechanism of the human body so disordered as to give the mind distorted thoughts and views of life!

A LARVA FOUND WITH ITS HEAD AT THE BOTTOM OF THE CELL.

In looking over brood constantly for disease I have found that one becomes more observing, and sees some things he never saw before. Last winter, in giving a talk on bees before a Young Men's Christian Association meeting I told them that in all my experience I had never known a young larva to spin a cocoon and to change from the larval state to a perfect bee with the head toward the bottom of the cell, possibly because larvæ instinctively sleep with their heads in the direction of the mouth of the cell, ready to walk right out when mature. This season, however, I saw one such case, and I had the pleasure of helping the little witless thing from its cell, rear end first.

I wonder if it will know enough when it gets to work to come home when it rains.

ANOTHER BROOD DISEASE.

There are diseases that afflict the larvæ of bees, other than foul brood; and I have been surprised to find how general one of these is. It seems to be everywhere; and, while not very destructive, it should be studied, and, if possible, some remedy found for it. I sent a sample of it to Washington, and was informed that I need have no anxiety about it. The disease seems to kill the larvæ after they are sealed up, and at almost the same time, as they all look alike when the cell is uncapped. These dead larvæ do not decay in the cell as those do that die from American foul brood, but retain their form, and seem to dry up when they are removed by the mature bees. I observed it several years ago, and in some cases it was very bad—almost every larva in large patches dying, and then it would disappear and I would scarcely see a cell of it for two or three years. While it is not so bad as foul brood, the loss in the aggregate is considerable.

SHAKING INTO A BOX FIRST.

I have noticed that, as a rule, the advice given to beekeepers who have foul brood is to shake their bees upon frames, these to be taken away in four days, and a clean hive given them. After a little experience I have advised shaking into the brood-box or any other box for the first time, and after four days giving frames of foundation. This has seemed to work well, and I have failed to hear of a single case where disease has reappeared because the old brood-chamber was used without being disinfected or burned out. It seems well to make it just as easy as possible, within the bounds of safety, for beekeepers who have diseased colonies. I have been more careful with inexperienced beekeepers than with those of more experience.

Middlebury, Vt.

To be continued.

BEEKEEPING TAUGHT IN PUBLIC SCHOOLS

BY JOSEPH TINSLEY

In GLEANINGS for Nov. 1 I notice Dr. E. F. Bigelow refers to his experiment of teaching beekeeping to boys who, he says, are the sons of wealthy parents. I am pleased to inform your readers that we in Staffordshire are a great way in front of this. We have actually ten public elementary schools where beekeeping forms part of the school curriculum. The schools selected for this experiment were purely rural

ones, situated right in the heart of the country, and are naturally attended chiefly by sons of agricultural workers. Such teaching is bound to bear fruit in time, whether at home or abroad; and now we have made a start I anticipate the whole of the schools in rural districts will be drawn to adopt a similar course of study, and in time beekeeping will form the syllabus of every country school.

The photos will explain themselves, and were all taken at one particular school at different times of the year. The first four photos have previously appeared in that excellent little journal, *The Beekeepers' Gazette*, but I have Editor Digges' permission to utilize them in this direction, as it is not often that we are in front of our cousins across the water. The remaining photos have not previously appeared in any paper.

You will naturally ask how beekeeping came to be taught in the schools at all. It was chiefly due to my own personal representation and to the good work of our association (though at the same time I must admit that the education in this country is undergoing a vast change, particularly in rural parts) that the Staffordshire Education Committee agreed to the experiment. The difficulty then presented itself, how could the schoolmasters and mistresses teach the subject, not knowing it? Such obstacles can be overcome, and they were overcome by my giving them a series of lectures and demonstrations; and here let me remark that it was not only an easy task, but a very simple one. Highly trained men and women can be taught a subject, or, rather, the elementary portion of it, in a very little time. They are apt pupils; and when I explained the anatomy the enthusiasm for the subject was apparent.

I need scarcely say that the children exhibit no fear at all. The trouble is to keep them back. Each school is supplied with two up-to-date hives, with accommodation for the storing of 60 lbs. of honey, two stocks of bees, ten veils and a smoker, while there are extractors and honey-sieves to go from school to school. The children are thus educated in all the various branches. We already see some results by parents of the children buying a hive of bees instead of the pet rabbits, cats, pigeons, etc.

The educational feature has been a great success, and the financial side has also been satisfactory, one school having made \$15.00 from the sale of honey from the two hives.

At one school, where the schoolmaster has developed rapidly into a first-class beekeeper, an observatory hive was fixed in the school window, and this has proven an ex-

cellent educative feature, the children being able to observe the bees at work in every detail. It is intended to fit more schools in a like manner in the future.

The children are taken to the colonies, and a practical lesson is given, according to the time of the year. The scholars then write, unaided, an account of the lesson, thus marshaling their thoughts and setting them down on paper. These are very cleverly done. At some schools the girls are instructed in cookery, and these girls are taught the art of making bee foods. Woodwork is another subject that is being taught, and here also the boys are instructed into making articles for the apiary, thus making the subject doubly interesting and practical.

A profit-and-loss account is kept in all the schools by the children, thus enabling them to be keenly attached to a subject in which they have a personal interest.

Stone, Staffordshire, England.

HOW I STARTED BEEKEEPING IN A LARGE CITY

BY ALBIN PLATZ

On July 6, 1908, I started my career as a beekeeper on a small scale, engaging in the pursuit principally for the recreation it affords, and to keep myself and friends supplied with the finest and purest of all sweets—honey. I bought my first colony on the evening of the day mentioned, paying \$5.00 for it, which also included all fixtures, such as queen-excluder, super complete, etc. The day was exceptionally hot and sultry; and in order to confine the bees securely while they were being transported to my home the beekeeper of whom I bought them nailed a piece of wood over the entire entrance, excluding all air. They were thus confined over three hours, and I have often wondered why the combs did not melt down and the bees smother. However, no such thing happened, and I received them in first-class condition. During October of the same year I purchased my second colony of a woman in the eastern end of Cincinnati, for \$3.50; and from this colony I raised my best stock and queens. I bought both of these colonies too late in the season for them to store any surplus, but they went through the winter in fine shape and were exceedingly strong in bees in the spring.

Now, thought I, having read all of the literature on bees I could get hold of during the winter, and knowing it all theoretically, I can not fail to harvest a nice crop

of honey; for every thing presaged a good honey year. That was in 1909. But I was sorely disappointed; for not only was there no honey, but, on the contrary, I had to feed the bees to keep them from starving. That made two years of failure to start with—somewhat discouraging for a brand-new enthusiast.

Naturally I had to stand a good deal of chaffing and ridicule about this time, and many advised me to give it up, saying that it requires an expert to make bees produce honey; and, moreover, they never would store any surplus in the city where the pasturage is so limited. "Give me one more year," I said; and if the third season would prove a failure I would acknowledge myself beaten and throw up the sponge, so to speak. Well, the spring of 1910 rolled around, and I increased my two colonies to four by dividing. Fruit bloom and locust yielded nicely, and then came white and sweet clover; and with the latter, lots of honey. I had two swarms, and harvested almost 300 lbs. of honey, besides saving almost 50 lbs. in sealed combs to use for feeding if necessary. I sold my entire crop for 20 cts. per lb.

Every thing looked rosy to me now, and I made great preparations for 1911, intending to increase my six colonies to a dozen or more, and to increase my honey sales. But a fine surprise awaited me. One morning in early June, while examining my colonies I was shocked to discover American foul brood in one of them. I immediately sent a sample of diseased brood to Dr. Phillips, at Washington, and he told me the bees had American foul brood, and gave me instructions for treating it. Before I had his reply, however, the other colonies became infected, two of them being virtually rotten with the disease. Here was a fine state of affairs. No honey was coming in, and foul brood to fight! Well, I prepared six clean hives with full sheets of foundation, and gave them the McEvoy treatment, shaking some in the morning and some in the evening; and in no case did the disease reappear. It was cured completely; but the cure cost me over a hundred fine brood-combs and about 150 lbs. of sugar. Thus ended the season of 1911.

After having survived the most severe winter (1911) in forty years my bees came through in fair shape for 1912—no loss, although the average mortality was over 75 per cent. By swarming and making a few nuclei I increased to eleven colonies, and secured 415 lbs. of honey. I produce only extracted, and it sells readily for 20 cts. per lb. My best colony of Italians stored

155 lbs.; and my worst, a colony of Banats, 37 lbs. I have two colonies of goldens; and while they are good honey-gatherers, they are also great robbers; and after the honey-flow is over it is almost impossible to keep them under control. I had one case of robbing this fall, and carboic acid had no effect on them. As for the Banats, no more for me. They are extremely excitable, poor comb-builders, great stingers, poor honey-gatherers, and it is next to impossible to find the queen in a populous colony. All things considered, no strain can compare with good Italian stock. They are gentle, and by far the best workers.

Before I close I should like to give a few pointers to beginners. Adopt the ten-frame hive and stick to it. Don't practice stimulative feeding in the spring. Keep the best strain of Italian bees. Use absorbent cushions in wintering (not sealed covers), and don't tinker with the bees too much. By reading GLEANINGS and keeping a copy of the A B C of Bee Culture at hand, the theoretical part may be acquired to perfection. The practical part will naturally take care of itself.

Cincinnati, Dec. 12.

A SCHOOLTEACHER'S EXPERIENCE WITH BEES

BY V. ROSS NICODEMUS

The shades of night had already fallen when I arrived at the old beekeeper's stand, three miles from home. He expressed his doubts as to whether I could get my colony home; but I assured him that, if he would get it ready, I would run the risk. I had not gone far on my homeward way before I saw the reason for his doubts. The little box which served as a super jolted loose, and at every chuck in the road threatened to release the prisoners. I soon fixed this, however, by sitting on the hive; and, driving old Dobbin at a brisk trot, I arrived safely home without becoming aware of a single bee getting through the cover board.

Later I bought two more colonies, one of which died before spring. Every day when I returned home from a strenuous day's work in the schoolroom, I would slide the lid of the hive to one side and peep in just to see how the bees were getting along. This first colony I transferred to a modern hive. Later I clipped the queen's wings—too closely, perhaps, for she died soon afterward. In June I purchased two two-frame nuclei of goldens, and put them into new hives. I thought I was getting along nicely in the land of beedom. Little did I

know that my birchbark canoe was drifting down the stream instead of up.

The summer of 1911 here was poor, as it was in so many other localities. In September the bees almost starved, and no honey, although I had two supers on one hive all summer. I fed enough sugar to last them over winter. When winter began I had fine colonies; and when spring came I had none.

Not dismayed, however, I purchased another, and, profiting by my experience of the past, I was able to increase from one colony to six by buying some queens and a nucleus. I now have six, and secured about 40 lbs. of honey. This amount has cost me no small outlay of money, and a greater amount of time, and a few stings; but the experience that I have gained, and the pleasure I have had in working with them have amply repaid any deficit on that score. I shall try again.

Henrietta, Pa.

SOME EXPERIENCES IN LEARNING TO KEEP BEES

Reading Necessary as well as Practice; Clipping a Leg as well as a Wing

BY W. M. SHIELDS

My first experience with bees was with a colony of blacks which some one had advised me to winter in a hole in the ground. The hole was lined with boards in order to avoid dampness. The hive was put in and covered over with boards and earth, all being done according to directions given by my neighbor. When opened in the spring the hive was floating in water, and the bees were dead.

The same neighbor, by way of encouragement, offered me another colony at half price. I bought it, wintered it in the same hole, first taking care to put in a drain. This hive, when taken out in the spring, was covered with white mold, but it contained live bees.

For some years, through lack of knowledge of bees and their ways I never got beyond three or four colonies. I read much about bees in various papers, but the articles happened to be written for those who already knew something about them, and generally left me in a rather muddled mental state. Later I bought the A B C of Bee Culture, Langstroth on the Honeybee, and subscribed to GLEANINGS. It was after looking into these books that my interest in bees took a start. Then a two weeks' course in apiculture at Guelph kindled my interest into a flame.

My original colony was in a home-made unpainted box with fixed frames. I had, however, gradually changed to the eight-frame Langstroth hive, and last spring I changed to the ten-frame Langstroth. With these standard hives I purpose to stay.

I read and reread bee literature during the winter; and when spring came I very naturally felt that I knew all about bees. I knew just what I should do and what I wanted to do. My three colonies had been wintered in the house cellar, each one in a box by itself. When taking them out in the spring, one hive slipped and slid about on its bottom-board, and the bees came out in thousands. That was the first event.

Then I discovered that one colony strong in bees had no honey. What should I do? My reading came to help me in a jumble of "avoid spring feeding," "Boardman feeds freely in the spring," "better not to have to feed at all." I *had* to feed—no doubt about that; but how much or how little I could not remember, so I had to go back to my A B C book.

I knew, or at least I thought I did, all about clipping queens' wings, and knew how to find a black queen; for hadn't I read Doolittle on the subject until I could say every word? The colonies had been out of the cellar a day or two when a growing anxiety about these wings led me to try things *a la* Doolittle. My wife thought she would like to help me. The day was cold and windy, so we took a folding screen from the house to shelter the hive and ourselves, and then began the hunt. We had transferred the frames, and hunted the hive several times, when my wife ventured the remark that perhaps Mr. Doolittle was joking (I had been quoting parts of his article to her). It was no joke, I thought. At last my wife said, "Look! I believe that is the queen." In the excitement of trying to see a queen for the first time, our heads bumped. Our straw hats were knocked awry, and we lost sight of her. After a while she was found, and we clipped her wings. It will be well, perhaps, not to dwell on the furious bees we had that day, and, in spite of veil and gauntlets, on the stings we both got. I know now, of course, that, although it is a very good practice to clip the queen's wings, we had no business poking about a hive on such a cold day nor so early in the season on such an errand; but when a fellow is *sure* he knows all about it he is apt to overlook some details and forget to put two and two together.

Then a bulletin on foul brood, and the need for Italianizing, came to hand. I had read about foul brood; but Italianizing

was something new. I had apparently skipped it in my reading. I looked it up, though, and sent off for an Italian queen. This was in June, I think, just when the colony was strong and fit to gather in a heavy white-clover honey harvest. The queen arrived, and we (the same two), hunted long for the black queen, found her and killed her, and also destroyed all the queen-cells we could see. When the hive was put in order again, and the cage with the new queen was in place and the cover on, my wife said, "Now, Willie, are you quite sure it was the queen that you killed?" I immediately began to think it wasn't the queen, for now I come to think of it, it was perhaps a drone. However, I said to her, "What is the use of making a fellow doubt his ability as a beekeeper?" Didn't I know a queen? It was the queen, though, as after events proved.

A week or two after that, we looked for her majesty, and it was very easy to find her among her black retinue. We clipped her wings; but in doing it we also took a piece off one hind leg—by mistake of course. Fortunately she has turned out to be a good queen.

Now, this bit of Italianizing was rather costly. I should not have meddled with the hive at the time I did, for the operation stopped the laying of eggs for some days, and made a very marked decrease in the working force. I got little or no surplus honey from that colony, when, by delaying the Italianizing until after the honey-flow, I might have had two supers of honey to extract.

These are some of the more serious blunders I have made while learning, and I console myself with the thought that we all make mistakes. I should like to say for the benefit of other learners that, time and time again, I have found the reading I did, and experience obtained in other ways, of much practical value. The reading enabled me to increase my apiary from three colonies to six, all very strong, and with young queens to Italianize all of them, and to extract 185 lbs. of honey. I do not think the business of beekeeping can be carried on successfully without considerable reading combined with practice.

O'Connell, Ontario, Canada.

[Occasionally beginners accidentally cut off a leg of a queen while endeavoring to clip her wings. As far as the queen herself is concerned this seems to do no great harm. although the bees sometimes supersede a queen thus crippled. Clipping is really very easy, but still, if there are drones in the hive it is well to practice on them first. —Ed.]

HOW TO LOAD HIVES OF BEES ON A WAGON

The Necessity of Thorough Preparation

BY ELIAS FOX

I have been reading the dangerous and hair-raising experiences of the two boy beekeepers in moving 30 colonies of bees 40 miles on a wagon, p. 688, Nov. 1, and I am prompted to write a few lines on moving bees by wagon or rail, as I think I have had as much practical experience as any one beekeeper. These directions will apply especially to strong colonies in warm weather.

First of all, they should be in good solid hives; and if not so, the hives should be put in the best possible repair. If the frames are liable to loosen and crowd together, nail each end with a small nail, or insert between each two, at ends, small blocks, and nail fast: then make frames of common rough lath to fit the top of the hives, and lay screen on top, and put another frame of lath on top of this, and nail down through into the top of the hives. If they are very strong, and the weather is proportionately warm, nail a comb-honey super on top of the brood-chamber, and fasten screen on top of this; and if the super is full of empty or partially empty sections it will be all the better, as it affords better clustering facilities.

Now comes the closing of the entrance. The majority of people close it by tacking screen over it, which is the poorest way of all, for this reason: If screen is tacked over the outside of the entrance, it leaves it open the full thickness of the lumber, and the bees sometimes crowd the entrance solid full, and are so heavily clustered over the inside of it that bees can not get back, and thus cut off practically all this source of ventilation.

A much better and safer way is to take strips one inch or even $\frac{7}{8}$ inch square, and cut proper lengths to nail on the front end of the hives, making a rim on either side and at the top; then tack your screen firmly to the outside of this rim and let it run down to the alighting-board and tack a strip of any light material across this, one inch from the entrance; then you have a cage the whole size of the front end of the hives (less the three strips), and the bees will be just as comfortable as it is possible to make them in confinement, with no probability of any harm coming to them.

Be sure to do *all* nailing before dark, excepting the simple closing of the entrance. Should any small unnoticed holes

show leakage of bees when loading, calk them tight with cotton batting. Take a good bundle of it along with you to use in the same way in case of emergencies which may occur.

Load the hives firmly on the wagon with a liberal supply of straw under them; and when all are on have plenty of $\frac{3}{8}$ -inch rope so that you can have one strand passing over the middle of each tier of hives. Draw as tightly as possible, and fasten securely. Then take more of the same size of rope and go two or three times around the entire load horizontally, and take one turn around each strand of body rope and draw as tightly as possible each time, and fasten securely, and I will guarantee with this method of preparation in loading, roping, and side lacing, that bees can be hauled for hundreds of miles without loss of a colony if you keep them supplied with water.

Union Center, Wis., Nov. 18.

ONE SUMMER'S BEEKEEPING

BY OPIE QUEUE

This is to be a little record of my first year's beekeeping, so I shall start with the very beginning and gradually lead up to the grand finale which will be—but then, that is anticipating.

I started by buying from a friend a ten-frame hive of beautiful gentle Italians at a cost of eight dollars. I also purchased one shallow super with frames and foundation, ready for use, which cost another dollar. The hive was placed nearly in the center of the half-acre of ground that I call my own. Here, in the shade of an old apple-tree, Mr. K., who had sold the colony to me, opened up the hive while I stood at a respectful distance from him. I was very much surprised that he used no protection whatever—not even a hat, and he was bald-headed at that. Yet not a single bee attempted to molest him, and so I became bold enough to come to his side and look on; and I, too, remained unhurt.

When all necessary work had been done, and I had been shown some frames of brood and bees and the super was in place, Mr. K. left and my career began. Now, I knew practically nothing of bees. I had never in my life been within a rod of a closed hive, and never, to the best of my knowledge, within a mile of one that was open. Quite naturally I felt some trepidation as to the outcome of my venture. Yet I was determined to learn all I could to succeed and to make my bees pay for themselves. To that end I sent for the A B C

and X Y Z of Bee Culture; also for numerous government bulletins and other pamphlets treating on bees. And while waiting for these to arrive I had every one who pretended to know any thing about bees tell me about them. It would have been better, as I was soon to learn, if I had first gotten my books and had studied them, and then bought the bees; also, if I had not heard quite so many people talk.

It was the middle of June. Day after day I went down to watch my bees at work. They were busy from the first, as I could see by their hurrying in and out of the hive. Moreover, a delicious aroma of delicate sweets came to my nostrils. The temptation arose within me to open the hive and to peer into it. Indeed, though I had neither veil nor smoker nor gloves, the temptation became so strong that I could not resist. At first I raised the telescope cover just a trifle. When nothing happened I slowly took it off. Then I partly drew off the oil-cloth cover. Again nothing happened. I drew it off entirely, laid my hands on the frames, took one out, then took them all out, and nothing happened. Not content with this I took the super off entirely, and drew some brood-frames out of the lower chamber; and all the while not a bee came near me. This was on the second day after receiving my bees. It was all quite natural. The bees, being very busy, were also very gentle; and I, being a novice and very timid, was very gentle, and that is why I got along so famously.

As to the condition of things within the hive, I was on this occasion very pleasantly surprised. The foundation in the super was practically all drawn, or in process of being drawn. Indeed, I saw quite a little honey in the combs. As the days went by, the super gained noticeably in weight. Seven days of beautiful weather and uninterrupted flow filled it completely. It had the weight of a box full of lead. I telephoned to a beekeeping friend in the city, asking for advice. He told me to get some more supers, frames, and foundation. I asked when the new super should be put on. He said that he generally waited till the combs in the first super were partly capped over.

The next day I got five shallow supers, 100 frames, two pounds of foundation, a veil, a smoker, and a pair of gloves. Having prepared one of these supers, I waited for a sign of cappings in the first super. Alas! day after day went by and I could not find a trace of cappings. The bees got lazy, and would not work. The brood-frames contained numerous queen-cells. These, as

I saw them, I religiously cut out. In doing this I was following a bit of advice that some one had given me. I did this daily until the fourteenth day after I had received my bees. On the fifteenth, confident that things were in a safe condition, I left home to attend a convention that was to last a week.

It was on Tuesday afternoon, about 2 o'clock, when I returned home. I found a great uproar within my household. My wife was pale and panting; my mother-in-law was half sick; and the farmer from the neighboring field sat on his plow, scratching his head. My bees had just swarmed and hid themselves to regions unknown.

I have always been by nature somewhat of a fatalist; and when I was confronted with this situation all I said, or at least thought, was: "Well, it's too bad; but then, if they are gone they are gone, and that is the end of it." One colony of bees I still had, so why should I lament about the other that I didn't have?

Now another bit, not of advice, but of ignorance, came into play. Where I received this information, or whether I received it at all, I am unable to say. At any rate, I was firmly of the opinion that it is not the old queen, but the young one that leaves with the swarm. I reasoned thus: The young queen left with the swarm, therefore the old queen is still in the hive. I found numerous queen-cells. But, I thought, if the old queen is here, what is the use of the queen-cells? Out with them! I didn't want any after-swarms.

And the result? Well, it was something like this: Every day I went down there and looked for eggs and brood. I found neither. Whatever of queen-cells those very foolish and very frivolous bees had the temerity to build, I forthwith cut out. After two weeks had passed by I began to get worried, and telephoned to Mr. K. "That's bad, awfully bad!" he said. He promised to come out the next day. He was true to his word. Moreover, he brought another hive of bees with him.

For the purpose of getting queen-cells we put a frame of eggs and brood from Mr. K.'s hive into mine. Then we waited for results. A week later, when Mr. K. came again, not one cell had been built. Looking over the combs we found eggs promiscuously scattered about in the cells. Instead, however, of being attached to the bottom of the cells as they should have been, they were attached to the sides. Mr. K. said: "Laying workers!"

We carried the hive about 60 yards away, and there shook and brushed all the bees

into a large patch of tall weeds. Then we returned the hive and frames to the original location, and gave another frame of brood to it. Several days later, when I looked over the hive, I found some more eggs. The laying workers were still present in the hive. By telephone I told Mr. K. of it. He came again, three days later, and brought a young queen with him. Again we carried the hive away—fully a hundred yards this time. We were careful to shake off every bee, both from the combs and from the hive. Having returned them we put the new queen, caged, into it. Mr. K. warned me not to go near it during the next week. When he returned we found that the queen had been killed. Moreover, we still found the eggs of laying workers. What is worse, there was not a drop of honey in my hive, and thousands of dead bees lay scattered about—a case of robbing. Worst of all, Mr. K. discovered traces of American foul brood, not only in my hive, but also in his. You have probably heard of that cataclysm when thunder struck the toad! A very thrilling sensation, to be sure! I can sympathize with the toad.

Mr. K. was much worried. He had had the disease in his apiary the year before, but thought it was cured—indeed, had been sure of it. He immediately proceeded to treat the hives. There was but a handful of bees in my hive, so he broke it up entirely, burying the diseased combs (there were only a few of them) and putting the others into his own colony, from which he likewise removed combs on which he could find the disease. He was sure that he would thus get rid of all trouble. I was not quite so certain of it. Indeed, after I had thoroughly gone over the matter in my books and pamphlets I was certain that he would not succeed. And he did not. As the weeks went by we buried comb after comb, giving in their place frames of foundation. About the first of September Mr. K. thought the bees were free from disease, and so brought another colony out. He expected a fine fall flow of honey. Half of all that would come in was to be mine. But there was no fall flow, except barely sufficient for wintering.

In spite of all this, however, I managed so to manipulate that I was able to credit my bees, though they were dead, with some profit. Here is where the grand finale comes in.

Mr. K. invited me down to see him extract his crop of honey. I was glad to go. When he had finished he put up twenty pounds of fine white-clover honey and insisted on my taking it home with me. I thankfully refused. Mr. K. is an Irishman.

A BEGINNER'S EXPERIENCE

BY B. KEEP

Continued from page 12

He persisted in insisting. Finally I yielded. In the evening I took my big bee-ledger from its little pigeonhole, and using a magician's wand, most solemnly put down on the credit side of it:

To 20 lbs. honey at 15 cts., \$3.00.

Thus had I a clear profit of \$3.00 from my first year of beekeeping.

And now, my fellow-novice, I will have the temerity to attach to the above a small appendix.

Never fool with bees when you don't know any thing about them.

Never fool with bees when you know just a little about them.

Never, never fool with bees when you don't know whether you know any thing about them.

But when you know that you know, and you don't give a snap if everybody knows that you know you know, then—

Don't fool with bees, but keep bees.

[As an afterthought to the above rather melancholy experience, we may say that most beginners (perhaps by luck) succeed in getting honey the first year without having all the troubles known in beedom as our correspondent seems to have had. If this were not true, we are afraid there would be very few beekeepers. But there are cases, like the experience cited above, when the advice received only seems to lead to more trouble and when every move seems to be just the wrong one. Our correspondent is surely correct in his observation that it would have been better if he could have secured his information from reliable textbooks, of which there are now many, instead of trusting well-meaning, but poorly informed neighbors.

For the benefit of other beginners who may not be able to discover just what was wrong in the above management we will say that merely destroying queen-cells will not always prevent a swarm. And if a swarm does issue, it is accompanied by the old queen, the colony on the old stand being left with queen-cells, one of which contains the young queen destined to be the future mother of the colony. Destroying all queen-cells again rendered the colony hopelessly queenless, and in time laying workers developed. The plan for getting rid of them, while commonly practiced, is not very reliable.

The diseased combs need not have been buried. They could have been melted up, and most of the wax, at least, saved, so that a little more might be added to the profits, which, had it not been for the kindness of the one beekeeper, would have been nothing at all.—Ed.]

All bottom-boards have the Cary feeder. I very soon discarded the flat Excelsior covers, and replaced them with double pitched covers having an air-space, and covered with asphalt roofing felt (the same as that used to wrap the hive body); no painting; no leaking; no warping; and all made of cheap $\frac{3}{8}$ or $\frac{1}{2}$ -inch lumber.

I must admit that no small part of my enjoyment in beekeeping is derived from the mechanical features of it—the nailing and painting, fixing up supers, and all the little things in anticipation of the next season. Another most enjoyable incident has been the remodeling of an unused chicken-house, whereby I have a dry cozy little honey-house where surplus fixings are stored, and where the extracting was done this fall. There is a chimney with a fireplace or stove, and during warm weather there is running water from a pipe intended originally for hosing the garden. The shanty, as we call it, is 8 x 12, and has an asphalt felt roof and concrete floor. The tar paper from the old roof was laid down on an inch of sand, and the concrete on top of that, so the place is positively dry. There was no frost on the windows all last winter. This season I found one colony queenless in April. One colony swarmed late in August, and five days later an after-swarm was put back. The prime swarm was reunited before cold weather, so that my number remains at ten, which I consider all that the locality and my time will warrant. One colony was found by the inspector in May to have American foul brood. It was treated by the McEvoy plan, and at the close of the season I took about 30 lbs. of extracted, which was not so bad after all. One colony I used for experimenting, but it gave about 25 lbs.; so that, practically, only seven of the ten can be credited with the 450 lbs. extracted, and 65 salable sections which I harvested. Owing to bad weather when fall flowers were blooming all colonies were very light in winter stores. One or two had practically nothing, so 120 lbs. of granulated sugar have been fed, and I am waiting anxiously the coming of another season, when I may try my hand at queen-rearing in a small way.

Heads of Grain from Different Fields

Bulk Comb Honey Brings 20 Cts. a Pound

I reported to you last April that I had saved all my bees but one colony, and that I had ten colonies in fair condition. I will tell you briefly my 1912 experience. I worked for both extracted and comb honey, or, in other words, I made all bulk comb honey out of my crop. I used the shallow frame for comb honey and the regulation size for extracted, and made a combination that seems to please my customers. I put it up in 2½, 3½, and 6 lb. buckets, and get 20 cts. per lb. for it. I closed the season Sept. 15, and I invoiced as follows: 1215 lbs. of honey, and my bees increased from ten colonies to 23, and all in fine condition for winter, either mild or severe.

TELESCOPE COVERS FOR WINTER PROTECTION.

I have adopted the telescope cover for winter protection that looks as if it would be a success. This telescope is 30 inches wide, long, and high, covered with rubberoid that slants to the rear with about 4 inches drop. This is stuffed, rammed, and crammed with forest leaves until it seems as if no cold air could get to the hive except at the front that faces east.

I am not prepared for cellar wintering, and do not believe I would swap my chances, as my bees are now fixed for a bee-cellar if I had one convenient. I feel reasonably sure that if I could save my bees from freezing such a winter as last, with only fair protection, that I shall have no trouble with them in any winter, as I now have them snug and warm. I put them away Oct. 2, and shall try to forget them until April 1, so far as care is concerned. These telescope covers cost me 68 cts. each; and as they will last as long as the hive I feel that they are not expensive.

GOOD OUTLOOK FOR ANOTHER SEASON.

I was surprised at some of the reports from Indiana regarding the small crop of honey. It seems to me, as an amateur, that 121 lbs. per colony, spring count, was not so bad; and had I expected such a flow from white clover I certainly would have been better prepared to receive it, and no doubt could have increased this amount considerably. From the white clover that we now see all over this part of Indiana, it looks as if next year would be a repeater.

J. F. KIGHT.

A Missouri Beginner

One day in September, 1909, I returned from work earlier than usual—about 3 P. M. My back yard seemed full of bees. I proceeded at once to get out the garden hose and make rain for those bees. It settled them all right, but in a bad place, in the midst of an old grapevine that had not been pruned for years. I had an old copy of "Facts about Bees," so I hunted it up and hurriedly consulted its pages.

About the first thing I saw was in regard to using smoke to subdue cross bees. I knew those bees in my back yard were cross, by the way they flew round and round, and kept up such a loud hum. So I made a smoker by wrapping cotton rags around the end of a ten-foot piece of gas-pipe. The only thing I could find for a hive was an empty box about half as large as an eight-frame hive.

By pushing it with my smoker, I got it under the grapevine, and in position to receive the swarm; but how to get bees out of that mass of vines I did not know. I lighted my smoker, and by blowing through the gas-pipe I could make plenty of smoke. The smoke only scattered the bees among the vines. As a last resort I swung my smoker high in the air and aimed a smashing blow at one side of the cluster.

Every bee went to the ground with a thud, and soon ran into the box (I guess they were glad to go anywhere by that time).

I now read the booklet more carefully, and discovered that bees should be fed in the fall if short of stores, so I went to the corner grocery and bought a pound of honey. I put off giving it to them that evening.

The next day was Sunday. When I went out to look at the bees there were none in sight. I waited a few minutes; still nothing doing. I carefully turned up the box, finding one dead bee under it, nothing more. We had honey for Sunday dinner. My wife and neighbors had the laugh on me; but I had a well-developed case of bee fever.

The next spring I bought a two-frame nucleus in a Danzenbaker hive.

The years 1911 and 1912 have been poor ones in this vicinity; yet my two-frame nucleus has increased to two strong colonies that have given a fair amount of surplus each year.

EDW. G. SMITH.

A Simple Plan for Frame Wiring; Efficiency without Expensive Equipment

I have often noticed in the bee journals mention of devices made especially for wiring frames—in fact, some of them rather elaborate. As the following plan is so very simple and yet extremely practicable it will perhaps be of assistance to some who are doing this very necessary work in a roundabout way.

It might be well to begin work with the frames out of six eight-frame supers, as a convenient number to handle at one time and to pile them on the table in front of you at either the right or the left. It is understood, of course, that they have been punched the requisite number of times in each end. For a seat, use a couple of empty bodies on top of one another. This will give you a rest for your feet, and will overcome the feeling of being perched on a fence, besides putting you on a proper level with the table. Your knees will be well up in front of you.

Take a frame; place it endwise with the bottom-bar up between your knees. The spool of wire should be slung around your waist with a short piece of the wire itself. This is the outstanding feature. The spool will lie in the hollow above the leg at the waist line, and the friction will keep it neatly coiled, and yet permit of free unwinding.

As yet your two hands are unoccupied, and can be used to the best advantage—i. e., in threading the wire back and forth through the perforated end-bars. Have a pair of pliers on the super between your knees for cutting the wire when enough has been pulled off. Go through the whole lot of frames with this operation, simply giving the wire a bend around each end-bar, and then come back again to make them taut, the latter operation permitting of a rest to the knees as you now hold the frame side-wise between them, with the end-bars alternately up; and the loose ends of wire are best fastened by shoving them through the hole a second time and turning it round and round the horizontal wire close to the end-bar. No hammer or nails have to be used, and considerable time is saved.

Working on a suggestion of Mr. Morley Pettit, we used a fourth wire in our frames, placed about three-eighths inch below the top-bar. This wire catches the upper extremity of the sheet of wax, holding it close to the top-bar; and in every case where the supers were placed on colonies in the evening, and the bees allowed to run up from below, they were fastened securely by the bees.

The time of day does not make much difference; but in hiving swarms it would be best to use sheets

with wedges, as the bees will be piled on the foundation in great numbers all at once, and the heat they create is likely to bend the wax away from the top-bar and make a mess of things. I have gone a step further this season in wiring, and used only three wires, the third one being next to the top-bar, and the other two dividing up the remaining space. I feel sure that if used in the right way, the bees will do the sticking without pulling the sheets out of true. I have seen them even cut small holes in the foundation further down to get wax without secreting it. Evidently their first thought when entering a newly added super over the brood-nest or extracting-body is whether the foundation is secure. The top-bars used should be plain $\frac{3}{8}$ or $\frac{1}{2}$ inch. Having on hand a large stock of the bars with grooves for wedges we made use of them, but did not insert the wedge—an operation which takes more or less time.

Kirk's Ferry, Ont.

H. HARLEY SELWYN.

One Month's Record of a Hive on Scales

The following is a record of two frames of bees shaken on May 3, 1912, with a golden Italian queen introduced the same day. No brood was given.

WEIGHT OF HIVE AND CONTENTS.				
	7 A. M.	12 M.	6 P. M.	INCREASE
Sept. 3		22 lbs.	27 lbs.	5 lbs.
Sept. 4	26 lbs.	26 "	31 "	5 "
Sept. 5	29 $\frac{1}{4}$ lbs.	30 "	33 "	3 $\frac{1}{4}$ lbs.
Sept. 6	32 "	31 "	31 "	1 lb. loss; cold rain
Sept. 7	31 "	31 "	38 $\frac{1}{2}$ lbs.	7 $\frac{1}{2}$ lbs.
Sept. 8	36 "	36 "	43 lbs.	7 lbs.
Sept. 9	40 $\frac{1}{2}$ lbs.	40 $\frac{1}{2}$ lbs.	46 $\frac{1}{2}$ lbs.	6 "
Sept. 10	44 lbs.	44 lbs.	51 lbs.	7 "
Sept. 11	48 $\frac{1}{2}$ lbs.	49 "	54 $\frac{1}{2}$ lbs.	6 "
Sept. 12	53 $\frac{1}{2}$ lbs.	53 "	54 $\frac{1}{2}$ lbs.	1 " rain; 3 P. M.
Sept. 13	54 lbs.	54 $\frac{1}{2}$ lbs.	60 lbs.	6 "

It is to be noticed from the above, that, with the exception of the 5th, 11th, and 13th, all of the daily increase in weight came in from noon to 6 P. M., and that which came before noon on the 5th, 11th, and 13th, was very small. Is this to be taken as showing the rule or not?

Then, again, the sum of the daily increase is 54 $\frac{1}{4}$ lbs., while the net is but 38 lbs., or showing a loss of 16 $\frac{1}{4}$ lbs., which I attribute to evaporation of the nectar and the slight difference in the weight of the bees at 7 A. M. and 6 P. M. The daily loss from 6 P. M. to 7 A. M. was from $\frac{1}{2}$ to 2 $\frac{1}{2}$ lbs. On the 6th, there was a net loss of 1 lb. from 7 A. M. to 6 P. M. There was a cold weststorm all day which kept all bees at home, and forced evaporation with nothing coming in.

Sandwich, Mass.

E. B. HOWLAND.

[It is possible that the bees were getting this nectar from some source that yielded mainly in the afternoon; but we think it is more likely that the great number of field bees absent from the hive at noon would counteract the increase in the weight of the honey.—ED.]

Proper Size of Entrances; Mice in Hives

This season my bees made a net surplus of more than \$8.00 per colony, average, spring count, and increased 50 per cent. They are now packed for winter. Most of my hives are home-made, some single-walled, some two-story, and some one-and-a-half story. The top stories telescope one inch down over the brood-chamber, and rest on a $\frac{3}{4}$ strip.

I laid two rows of corn-cobs across the frames to give a passage from one side to the other, then put on trays of planer shavings that rest on the top of the brood-chamber.

Last winter the mice got into several hives at

the entrance, and nearly ruined the colonies. The hives being home-made, the entrances were from $\frac{3}{8}$ to about $\frac{1}{2}$ inch. So this time I fitted in pieces that closed the entrances to $\frac{1}{4}$ by about 12 inches. Do you think that will give them enough ventilation? Our weather prophets predict a cold winter because the corn shucks are thick, etc.; but I do not take much stock in it, and hope they are wrong. We have a fine prospect for white clover at present. My honey is about all sold locally, at 15 cts. for comb and 10 for extracted, net.

Walton, Ky., Dec. 5.

J. G. CRISLER.

[While it is difficult to give a definite answer to the above that will fit all cases, we should say that an entrance $\frac{1}{4}$ x 12 inches should give more than enough ventilation for the average colony.—ED.]

How Bees Eat Dry Cube Sugar in Winter

Since my letter in regard to wintering bees on dry cube sugar appeared in GLEANINGS, Oct. 15, p. 663, I have received several rather sharp calls along one line—*viz.*, that sugar, before it can be used for wintering bees must be made into a candy or syrup—that it is impossible for bees to live on dry sugar.

Cube sugar will absorb a large amount of moisture from the air in a hive during frosty weather, and at the same time will retain its shape and will not become sticky or runny. After it has absorbed a certain amount it refuses to absorb any more. When in this condition the bees readily work on it.

There is a slight loss in this way of feeding, due to the fact that the bees eat the cubes down to a size where they will fall through between the frames. During the spring housecleaning fewer some colonies will carry these small pieces of sugar out of the hive, while others will work it over till there isn't a crumb to be found.

It is possible for bees to winter on dry cube sugar placed above the brood-nest.

Newark, N. J.

CHARLES S. SHARP.

An Explanation

It seems, p. 755, Dec. 1, that Dr. C. C. Miller doesn't understand me. I do not intend to convey to the minds of the readers of GLEANINGS the idea that they should develop a taste for honey they do not like. What I meant is, that honey should be called by the name of the blossoms from which it is gathered, leaving to the judgment of the consumer which honey he prefers, hereby giving all honey, regardless of color, an equal selling chance. We do not buy potatoes as blue, red, or white, neither sugar nor any other staple, except tea. We name them by their kind. We all have our preferences, regardless of differences in opinion. I hope this will set me right.

Cincinnati, O.

HENRY REDDERT.

Dandelions and Buttercups in December

I have 35 colonies of bees, and at 9 o'clock in the forenoon of Dec. 6, this year, I was in my yard, and the bees were flying all about me, like summer—something quite unusual for December in this latitude. On our hillside we can now find dandelion and buttercups in blossom. Clover is looking fine, and we hope to be numbered next year among the first in the way of white clover in the comb.

Cherry Valley, N. Y., Dec. 9. WAYNE SNYDER.

28 Colonies Increased to 76

I successfully wintered 28 colonies, and have increased them to 76 good colonies, and harvested 3300 lbs. of honey, which is not so bad for a beginner.

Lowville, Ont.

GEORGE BRADT.

Our Homes

A. I. ROOT

The sabbath was made for man, and not man for the sabbath. Therefore the Son of man is Lord also of the sabbath.—MARK 2:27, 28.

WHAT SHALL WE DO ON SUNDAY?

The first thing I read in your journal is *Our Homes*, therefore I value it most. I wish Mr. A. I. Root would some time give us a talk on what we *should* do on the sabbath, as he often tells of what we *should not* do. As I am a beginner in Christian Endeavor work I am looking for information to help the society here.

Lakeside, Cal.

G. E. PHILBROOK.

My good friend, the Bible enjoins us to remember the sabbath day to keep it holy, and therefore the first thing to consider is the word holy—what does it mean? How did the Savior spend his sabbaths? For one thing, he went to church. We read in the fourth chapter of Luke, sixth verse, "And as *his custom was*, he went into the synagogue on the sabbath." Again, we are told, I think repeatedly, that he healed the sick on the sabbath, and so we are told two things—he attended church without fail, and he also ministered to those who were sick and suffering on the sabbath as well as on week days. When the Pharisees complained about his manner of keeping the sabbath, he asked who it was who would not go to the rescue of a sheep or an ox that had fallen into a pit on the sabbath. If I did not attend regularly the preaching on the sabbath, and also Sunday-school, I should feel guilty; and I do not see how any follower of the Lord Jesus Christ can be excused for absenting himself from some place of worship on Sunday unless it is next to impossible to get there; and I should not be particular what church it was. You are pretty sure to hear a good sermon in any of the evangelical churches, and you are pretty sure to be among a lot of good people who love the Lord whenever you go into any Sunday-school.

While I do not believe in promiscuous visits on Sunday, I think it is right and proper that you should do what you can to help or relieve sickness among the relatives or immediate neighbors. If you know of any thing you can take them that will cheer them up, say fruit or flowers, by all means do it, even though it is Sunday. If you have reason to think that the sunshine of your presence will do them good, do that. Carry something to read to those who are unable to read; and if opportunity offers, read the Bible; and it is a nice thing also to sing a hymn to those who are lonely and are glad to see you. If you can not sing a hymn, get right at it and learn some simple hymn. The Sunday-school is a

splendid place to learn such hymns. Our recent hymn-books contain gems of thought as well as music, and are wonderfully cheering to one who is sick and discouraged.

Now, there are some people I know who think they must sit at home and read when not at church. I do not agree with this. One of the most important things in order to feel well, and especially if I want to keep well, is to have exercise in the open air, even if it is Sunday. If I were a farmer, and had live stock and crops, I would go out over the farm and "count my blessings," see how much I have to thank God for, which I did not think of during the week. Give the domestic animals something they are fond of—a lump of sugar or an apple to the horses and colts. Make them feel, as well as everybody else, that Sunday is the day to have a good time. Get acquainted with your domestic animals. I need not tell you, for I have said it so many times, that a hen lays more eggs when she gets well acquainted with you, and feels happy every time you come around. Sunday is a good day, too, to encourage a *closer* acquaintance. Above all things, look at the flowers; and do not forget to raise your thoughts to the great Giver of all things in thanksgiving and praise. Like the animal that has fallen into a pit, as mentioned by our Savior, there is almost always something to be done for the relief of suffering in your community or neighborhood among the people or among the domestic animals.

Of course, Sunday is a time when you have more leisure to read. On Saturday I usually have a great mass of periodicals—journals given to farming, gardening, poultry, and many other things; but these are all put away just before I go to bed Saturday night; and Sunday morning, when I first get up, I go for the *Sunday School Times*. Several years ago I said if you can afford only one periodical besides your town paper, let it be the *Sunday School Times*; and I have no reason to change my mind in regard to it. It is the best religious periodical I know of—at least of its kind. After the *Sunday School Times* I would suggest periodicals published by your own denomination. We take the *Chicago Advance*, which is a Congregational organ; but I do not feel as free to read it on Sunday, *every bit of it*, stories and all, as I do the *Sunday School Times*.

I want to speak once more about our domestic animals. I have heard of farmers who put off salting their farm stock till Sunday because they would have *more time* on that day. I do not believe that that is exactly the thing to do; but at the same time we should bear in mind that a merciful man is merciful to his beast. I do not know but it would be right and proper for a Christian man to look all of his domestic animals over with a little more thoroughness on Sunday than on any other day—look after their happiness, and see that their water and feed are just what they ought to be; and, if it is a possible thing, teach them so that they will look forward to it and expect it, and to expect, too, that Sunday is a day of rest.

There is one thing I like about automobiles. They permit the whole family to get to church without depriving the tired horses of their rest. But when I say this I recognize, sometimes with sadness, that automobiles too often go in some other direction than toward the church on God's holy day. Sometimes after having been to church they take long spins somewhere else. The different automobiles that Mrs. Root and I have owned have never been used except to go to places of worship or perhaps to call on near relatives. Until my mother died it was my practice all my life to make her a little call every Sunday afternoon, and I did this before I was a professing Christian. Very likely these Sunday-afternoon calls had much to do with the fact that I finally accepted my mother's religion and her Savior. Since her death I have been in the habit of calling on my sister, for only one is left now out of four.

And now, my dear brother, I have given you a pretty good account of the way in which I spend my Sundays. Perhaps I should add, however, that whenever I am induced, during these calls I have mentioned, to talk about business or week-day duties, my conscience is not as clear and as devoid of offense toward God and the Master as when I have tried to keep in mind the command to keep the day holy. Perhaps we can not do better in closing than to quote the 13th and 14th verses of the 58th chapter of Isaiah:

If thou turn away thy foot from the sabbath, from doing thy pleasure on my holy day, and call the sabbath a delight, the holy of the Lord, honorable; and shalt honor him, not doing thine own ways, nor finding thine own pleasure, nor speaking thine own words, then shalt thou delight thyself in the Lord; and I will cause thee to ride upon the high places of the earth, and feed thee with the heritage of Jacob thy father; for the mouth of the Lord hath spoken it.

SHOULD MURDERERS HANG!

I have just read Mr. Thomas Dewees' letter on page 459, July 15. It is a good letter, and breathes a Christian spirit right through. All the same, I am firmly of the opinion that it is necessary to hang the murderer as a deterrent to other evil-disposed persons.

I have read a lot about the statistics of the United States, and there is no doubt that the crime of murder is increasing there to an appalling extent. Butler, the man who murdered and buried his victim, Le Weller, within a quarter of a mile of one of my bee-farms on the Blue Mountains, was brought back from San Francisco, and hanged; and there is no doubt in my mind that it had a salutary effect on others of a like stamp. There are some men who are simply human tigers; and to imprison these brutes for life, which means here really fifteen years, and then let them loose among the people again, is, I think, criminal.

A little time ago a man in Sydney, named Phillips, ravished and murdered his nine-year-old daughter while he was under the influence of drink. He was condemned to death; but the ministry in power here at present will not hang, and they commuted the sentence to imprisonment for life—that is, fifteen years.

A little while ago a young man only twenty years of age, a fine-looking fellow, only just married, murdered a man named Travassius. He traveled thirty miles to commit this murder. He made arrangement with his victim to meet him in his own home at 8 o'clock in the evening, brought a plow-coulter with him, and a razor; and while they were talking together he suddenly struck his victim over the head with the coulter and then cut his throat. He was sentenced to death, but the ministry commuted the sentence to life imprisonment—fifteen years. Now, this young fellow is a type of the human tiger. He was not drunk. He simply wanted money, and he murdered a man for \$250, and then cleared off for Melbourne and enjoyed himself with his wife.

Just a little time after this, a half-caste committed an assault on an elderly woman in Sydney; and the very first thing he said when the police caught him was this: "They can't hang me; they did not hang Phillips." You can see how he reasoned. At one time they used to flog people here for certain crimes. Then the public cried out at the futility of the practice, and flogging was abolished. Some time afterward an epidemic of garroting broke out; and the ordinary punishment of imprisonment proving no deterrent, the flogging law was brought into use again. The magistrates sentenced the culprits to six months in jail and two floggings of fifteen lashes each. Still the garroting continued. So the magistrate sentenced the man to one flogging and then to be turned adrift among his friends. The lockup where the flogging was to take place was surrounded by a crowd of his friends and sympathizers, and they could hear him howl as he got his punishment. Then he was pushed out among the crowd, and his friends had a chance of examining his back, and could get a fair idea of what flogging meant. Brutal? Yes; but it stopped the garroting. Is not garroting brutal? Is not murder brutal? and is it not necessary to deal with these brutes as brutes? Murder is on the increase in New South Wales on account of not hanging, and I believe it is so in the United States also, for the same reason. MAJOR SHALLARD.

South Woodburn, Australia, Sept. 1.

While we are giving place to the above we also submit the following, which was furnished by our stenographer, W. P. Root, for our *Medina Gazette*:

THE RIGHTFULNESS OF CAPITAL PUNISHMENT.

As I write these words, Sept. 23, preparations are being made in Charlestown, Mass., for the execution, by electricity, of the third man, in the same chair, in the space of just four months. The first was Rev. Mr. Richeson, who ruined a girl in his flock and then induced her to swallow a capsule filled with cyanide of potassium. He was executed May 22, after a full confession, "for Jesus' sake," as he put it.

A week ago a Mr. Spencer was executed in the same chair for playfully shooting a lady schoolteacher when trying to rob her of her money.

The case under way is that of Mr. Chester Jordan, of Springfield, Mass., who murdered his wife and cut her body to pieces as did Mr. Crippen, the Detroit dentist, in London.

The case of Mr. Beatty, of Richmond, Va., who shot his wife while she was in his automobile, a year ago, and for which he was executed on the 24th of last November, is still fresh in our minds.

This whole business is sad indeed; but some seem to see no sadness in it except the ending. The sadness is in the thought that the three men first mentioned, and probably all five, singularly gifted, mentally and physically, should have been so destitute of all moral perception as to choose deliberately a course of action which they knew would haunt them to the grave, even without detection, but which, after all, they knew they could not escape. These men had it in their power to make their names honored for all time as did the late Wm. Booth, of the Salvation Army; but instead they shook a dead tree to get the apples of pleasure, and pulled down on their own heads the fire of Sodom. In each of the five cases the matter was rendered many times worse by the fact that the victim was a helpless woman; for, bad as is the murder of a man by anybody, the sand-bagging and shooting of a woman is the limit so far as depravity is concerned.

During the late campaign some literature was sent out here, arguing against the execution of such artists in human slaughter as I have mentioned. I am glad the law will stay as it is. Statistics in such cases prove nothing by saying that Michigan has no executions and only a few murders, while Ohio has more. A difference in nationality would account for all that. Cleveland has a foreign population of fully 400,000 and Cincinnati about 250,000, while Toledo, Columbus, Dayton, Youngstown, and Akron would run the number up to all of Michigan's population, the latter being composed largely of the most progressive people from the eastern part of the country. But even the Michigan law does not prevent murder there.

Unless we know how many men have checked a murderous thought when a possible rope has dangled before their eyes we can not decide those questions by statistics; but it is easier to believe that a man will refrain from murder if he knows he will probably be hanged for it, than to suppose he will abstain from it with only a penitentiary sentence back of him and a probable early pardon.

The rightfulness of inflicting death by law is questioned. That depends on our standard of right. I assume it to be the Mosaic code. Alfred the Great, a thousand years ago, made the 20th, 21st, and 22d chapters of the book of Exodus the basis of common law in England, and it has been so regarded since that time; and that basis is also the standard of law in the United States. As a clear conclusion from that law, or a comment on it, we read in Numbers, "If he smite him with an instrument of iron, that he die, he is a murderer; the murderer shall surely be put to death." That law was nowhere deprecated by Jesus Christ, nor does it antagonize his doctrine. He came to

preach to men as individuals; but he left society, organized under law, to bring down its own tremendous malediction on those who take human life when in the commission of crime.

Of course, some murderers should not be executed. If it could be proved positively that the present incumbent of our jail slew his wife, his apparent mental condition would seem to call more for confinement than rope; or when men get into a row over a line fence, or several engage in a wholesale carving rumpus, and one gets laid out, it is impossible to say who is wholly to blame. But when we consider such midnight assassinations as that of the Coy family here, and the devilish cruelty of Blinky Morgan and his gang as he held Marshal Frazier up here, in December, 1886, while the villains blew up our county treasury, and afterward shot the policeman dead, near Ravenna (for which he was hanged), the subject of mercy ceases to be mercy when dealt out to those who never showed any, and despised it when they saw it. As it is, only about one murderer in eighty is put to death in this country, as our criminal courts are so defective in their operation—vastly inferior to those in England.

Still, I am greatly opposed to capital punishment; but I am not so much opposed to it as I am to the cause and necessity of it; and it can be done away with, with neatness and despatch, as soon as we get the consent of the gentlemen sirs the murderers themselves.

W. P. Root.

As if to add emphasis to the communications above, the papers tell us that Shrank, the would-be assassin of Mr. Roosevelt, followed him from New York to Milwaukee, through about ten States, in order to do the deed in a State where capital punishment is not inflicted. This shows conclusively how such men reason.

"PROFITS" AND "DOLLARS."

Dear Friend:—To me GLEANINGS is one of the best journals I ever read, taking it from cover to cover. To my mind I never read its equal. I am 68 years of age; 52 years of that time I may say I have been a member of the Methodist Church, in good standing, so you see I can take great pleasure in your Home talks.

In the issue for Oct. 15 there is considerable attention given to temperance. In it and other issues you combat earnestly the evils of intemperance, but you seem to me to wrestle with the effect, instead of the cause, of that unnamable evil.

I am not going to lecture you, for I am not able, because I believe you are doing your part to keep the light of truth and humanity burning on the altar.

1. What would happen if congress and the legislatures would pass laws to prevent any profit being made out of the liquor business, tobacco business, or any other evil business?

2. How many people would engage in those vile businesses, if there were no dollars to be made out of them?

Nelson, B. C., Oct. 27. GEORGE FLEMING.

My good friend, I thank you for your kind words; and my opinion of the points you make, 1 and 2, is that you are exactly right. But what are we going to do? How can one consistently vote for Chafin after his unkind and unchristianlike fling at the Anti-saloon League because they have happened to differ with him in regard to meth-

ods? See Special Notices for Nov. 1. I am certainly heart and soul in favor of removing the temptation by cutting off this profit from the business. I have already mentioned that in Cuba, where I spent one winter, intoxicating liquors were sold at almost every country grocery. A man could get enough whisky for a penny to

make him drunk, and a child could get a cent's worth of whisky in a tin cup; but intemperance there in Cuba was nothing to be compared with what it is here in the United States; and especially was that the case before "we, the people of the United States," carried over to the Cubans our American beer and other liquors.

Poultry Department

FLORIDA FOR POULTRY.

Dear Mr. Root:—Many letters have been received, asking if Florida was good for poultry. These and other inquiries about the country have gone unanswered because the writer was too busy to reply to so many. Perhaps GLEANINGS will be kind enough to carry an answer that will reach and relieve all these anxious ones. After three years of careful investigation I can say, without reservation, yes. Below are some of the advantages. Land is cheap; housing costs almost nothing; no long hard winters call for expensive houses and intensive care. Prices are good. If one will use open roofless pens or houses in which to keep his birds they will be healthy and free from vermin. They can be hatched at all seasons of the year; but I suggest that one cut out the rainy season. Now is a good time to start the hatching. Yesterday morning as I passed a neighbor's I caught sight of a bunch of turkeys, and remarked that I would be around Thanksgiving day. He said they were all gobblers, and would need to be eaten that day or Christmas. But he added that he had hopes of perpetuating the flock, as the old hen was faithfully incubating a batch of eggs. Think of it, you frost-bound people—young pullets in November! The weather is favorable. They should do well.

A surveyor is away from home so much that he can't raise poultry, no matter how fond he may be of that work. I can get more pleasure watching a brood of chicks ("biddies" the Floridian calls them) than I can by watching a championship game of ball, and I have been a fan over 40 years. I must follow my profession, and that cuts me out of a lot of fun with the biddies. A man must live with his flock every day of the 365 if he would make it pay, and a surveyor can't do that. My work called me to Lee County three weeks of September, and fifteen days of October were spent on another job besides many single days away from Parish. So I cut out the practical side of chicken culture and confine myself to observation. Eyes and ears are open all the time for all facts that bear on this interesting subject, but I claim to be only a "looker on."

The chief drawback down here is the cost of feed. Long hauls from the North make heavy freight bills. The middleman comes in for a big profit. Of course, feed is high; yet all the poultrymen of whom I have knowledge buy it rather than raise it. Mr. Stevens, at Alva, keeps 600 that roost in his orange-trees and feed on dry mash from old boxes. He spends not one per cent on equipment, but buys all his feed. Mr. Throop, at Enterprise, is in the business big. He has 2000 hens the year round, that clear him at least \$2.45 each per annum. He says it is better than a grove. He raises no feed, preferring to give the time to personal care for his flocks. The houses are cheap low sheds with old fertilizer-sacks for sides. They cost scarcely a hundred dollars for the whole outfit. A writer who makes his living at Clearwater out of his White Leghorns, said in a recent number of the *Florida Grower*, that he bought all his feed last year and cleared \$1.40 per hen.

This man goes in for more expensive housing than the others. He writes that he "would as soon think of sleeping with a leaky roof over his head as over that of his chickens." Fine sentiment, that, but only sentiment. Down here the roofless house is the kindest place in which to keep your pets. There they are healthier, and freer from insect pests than when under roof. There are no kinder people than Mr. and Mrs. W. A. Halsey, of Terra Ceia Island. They shut their chickens up in roofless coops or houses the year round because they are healthier and more comfortable there, and lay well. Last summer, when everybody else's hens were on a strike, and no eggs could be bought in the country stores, theirs were shelling out the hen-fruit, keeping them supplied with all they could use, and they never stint themselves.

The Halseys were formerly in the poultry business, but now have only enough for their own table. They live off of the returns from 700 grapefruit trees on their ten acres, which nets them \$5000 or better per annum. Mr. H. came to Florida 25 years ago from Chicago. His experience was that of a city man. He knew nothing about farming. Having no capital, he worked at day labor as he could find something to do. When he got a chance he started to raise poultry. He saw that those who let their hens roost in the trees with a piece of old stovepipe about the trunk to keep the varmints away had no trouble with vermin and disease, and those who built houses for them had no end of trouble. Therefore he adopted the roofless house. Later he took up with the bottomless coop resting on the ground, which the poultry papers of those days were suggesting. It was the Philo system long before Philo hit upon it as the way to make money. In this case it was adapted to the conditions where it was to be used, which is the secret of success in every business, in every clime. Adapt yourself to your condition, and stay with it, spells success everywhere.

The Halsey plan is a light-weight bottomless coop set on Bermuda-grass sod, and moved every two or three days. There is an orange-box for a double nest in one end of the coop, which last is 8 feet by 8 feet on the ground. Its two ends are shaped like a capital A. It has two cross-pieces that strengthen it and serve as roost. It is enclosed with wire netting. Twelve hens spend their whole laying experience in it and enjoy it. As I told above, they lay well, much better than those that run out on the neighbors' land, and they are never in the way in the truck-patch. Fresh water is supplied, and they get a quart of mash in the morning, and a pint and a half of wheat in the afternoon, to each coop. During the trucking season they get plenty of lettuce. The rest of the time, grass furnishes their green food. It is not unusual to see the Philo system in use here, just as its author directs for city backyards and house-tops in the North. There seems to be no effort to adapt the method to conditions. Proper adaptation to location and surroundings is needed in all things. When the farmer comes down from the North he must forget what he knows, and

learn over again if he would get the best results in the quickest time. Then he needs to bring either enough money or enough time and ability to work so as to carry him through several failures. As a rule the road to success begins on the failure route, and in many cases it is a long way to the proper turn.

As many are thinking of Florida I may do them a service by telling two stories—one of them of the friends whose method with poultry has just been set forth, the other of their neighbor and uncle, Mr. Chas. Blood. It cost Mr. H. about twelve years of his early manhood to get a start here. He worked and struggled hard, but made little progress apparently. He was finding himself, and learning the growing of groves. Offered a job of caring for a grove, he went to Terra Ceia, a fertile island just north of the mouth of the Manatee in Tampa Bay. Having endured hardness, he was ready for his opportunity, and grasped it when it came. He found a good woman, one of the salt of the earth, and married. Then he made the first payment on ten acres. They built a shanty, and began the struggle for a home. He grubbed palmettos and stumps, grew truck, and cared for the grove of the non-resident. She raised chickens with his help; but all the time they were working for a grove as the goal of their ambition. They planted the seeds, grew young trees and budded them, and after a while they began to yield. Then they got on to Easy Street, and are now enjoying the fruit of their struggle. They bought the ten acres in 1899, 13 years ago. For about half of that time they have been getting a revenue from their grove, and for about five of them the revenue has been large enough to mean comfort. A quarter of a century, divided into twenty years of hardship and five of prosperity, is not bad, is it?

The most remarkable grove that I have seen in my rather extended travels over central Florida and the west side of south Florida belongs to the Mr. Blood mentioned above. There are thirteen or fourteen acres in his tract, with about 2000 grapefruit-trees on ten of them. House, barn, lawn, packing-house, and a pond occupy about four acres.

Mr. Blood is the apostle of intensive grapefruit culture. His trees are set 14½ feet apart, 200 to the acre. The old-time grove-grower sets them thirty feet apart, less than fifty to the acre, and for many years cultivates land that his trees do not fill, waiting for the time when, tall and stately, they will take all the space.

Mr. Blood believes in the present rather than the future, and wants the largest returns this year rather than a decade hence. As many trees to the acre as will take up the entire space in a few years, then all the water and fertilizer those trees will stand is his practice. The results are good. He began on Terra Ceia about seventeen years ago with nothing. His revenue by the time he had been there ten years was at least fifteen thousand dollars per annum. Since then his yearly average, clear of all expenses, has been fully that amount. Who can tell the value of an acre of ground that nets \$1500 annually?

He and his wife spent the summer visiting northern friends and relatives. For several weeks they were with a brother-in-law who owns a big wheat-ranch (two whole sections) in the valley of the Red River of the North. A large force of hands, with traction engines, gang-plows, and other up-to-date machinery make this 1300-acre farm very profitable. It is the ideal of modern farming; but our Florida friends prefer their thirteen-acre grove. They live easy, in the best climate in the United States, with no rush, and get more comfort and as much money as the big farmer. One acre of their farm is worth a hundred of the bigger one. Comment is unnecessary. The story speaks for itself. If one wants to know Florida's possibilities, there they are.

Please notice that these successful people learned the business through struggle and failure, and that their success came after years of waiting. Gold grows on trees here, but one must first learn how to grow the tree. Time, patience, hard work, grit, and many a disappointment are elements of life here as elsewhere; but the opportunity is great, and conditions favorable. Come and see for yourself.

Parish, Fla., Nov. 21.

F. M. BALDWIN.

SITTING HENS VS. INCUBATORS.

Our readers will remember that I have several times brought this matter up. Let me go over it briefly. Last winter I filled our incubator with eggs by standing them on the small end, and thus got in quite a few more than the incubator was made for, proposing to take out the unfertile eggs after three days. But that night I found a sitting hen, so I took fifteen eggs out of the crowded incubator and gave them to the hen. She managed in some way to have almost every egg fertile; but the incubator made only about two-thirds fertile. The experiment was repeated with like results. Finally our good friend Keyser, well known in poultry circles, announced that he took some eggs from the incubator at testing time, which showed no sign of fertility. He gave these to a sitting hen to "keep her going," but forgot about it, and in three weeks' time she hatched quite a few chicks. In other words, the eggs that would not show any sign of fertility in one of the best up-to-date incubators were, the greater part of them, afterward made fertile by the sitting hen. I found the same true with duck eggs. Sitting hens produce ducks from almost every egg; the incubator does it with only a little more than half as many. I submitted this question to incubator men and others; and I think the general verdict, although sometimes reluctantly given, was that a sitting hen is possessed of some "trick of the trade," or whatever you may call it, that beats, if not all incubators, the greater part of them, in getting the germs in the egg to start. In my investigations I notice that the eggs under a sitting hen have a greasy or oily appearance not found on eggs in the incubator; and a writer in the *American Poultry Advocate* for June, last year, has quite an article on the matter, from which I clip the two following extracts:

He believes that the oil on the eggs which are set under hens plays an important part, and goes on to say that some experiments have been conducted with a combination of the use of moisture, hen oil, and carbonic-acid gas; and that the difficulty was the absolute control of the factors. The few hatches have given great hopes of being able to accomplish something worth while when the control of these factors was learned.

The presence of more oil on eggs under hens than in incubators was brought out at the Oregon station. The amount of oil was also found to be

greater by seven or eight times when eggs had been incubated under her two weeks than at the beginning. By removal of eggs from the hens to incubators it has been found that the oil on the shell disappears in large part. In regard to the oil, Prof. Brown believes that it checks evaporation, since it has been shown that there is a greater circulation of air under the hen than in the incubator, while at the same time evaporation is less; but the oil may have other important functions that we as yet know nothing of. (Personally, I believe that the hen feeds the chicks in the eggs by the absorption of this same oil through the shell. An experiment proved to me that the hen does secrete something, whether oil or what not, which goes through the shell into the chick or egg during incubation. I took an egg from under a hen, which had been in process of incubation for nearly three weeks, and another from an incubator that had been in incubation for the same length of time. Both eggs were infertile and intact, and I broke them and fried them. I endeavored to eat the egg from under the hen; but the rank, strong garlic taste compelled me to forego the pleasure. The incubator egg had no disagreeable taste whatsoever. This is conclusive proof that the hen does do something for the chicks in the egg which the incubator does not; hence the reason why a hen generally hatches better than the incubator.)

This oil mentioned above is, no doubt, the oil secreted by the hen to smear on her feathers to shed water during a rainy time, and it is, no doubt, the same oil that we get out of a fat hen. Now, suppose we have a bottle of "chicken oil," and oil the eggs once or more when put into the incubator. It would stop evaporation, and prevent the egg from drying out, particularly when the incubator is not located in a damp cellar. You know how dampness has been highly recommended for the incubator room, even to keeping water on the floor. Who can tell us more about this matter? Has anybody tried oiling the eggs with chicken oil? I do not think we need to worry about its doing harm. The nicest lot of chickens, or about the nicest lot I ever grew, were from a lot of the muddiest eggs I ever saw. In fact, they were so plastered with mud I thought they would not amount to any thing, as I was too busy to wash them off. The hen hatched every egg with about the strongest chickens I ever saw. Now, if covering them with mud, or a sticky or clayey mud, such as we have here, did no harm, but, rather, good, then we have reason to believe that a little chicken oil applied every little while would not be a bad thing. Just one more suggestion:

A sitting hen sometimes if not usually pulls off all of her feathers where she touches the egg with her body. This naked body looks greasy and feels greasy. In fact, she squeezes the eggs up against this greasy body of hers with her wing. Have you not seen a sitting hen, when chased off the nest, carry an egg or two under a wing?

TURKEYS, CHICKENS, AND BEES.

See these two clippings from the *Ohio Farmer*:

I notice in your issue of Nov. 2 an article concerning a "prolific turkey hen." Mr. Harris states that his turkey hen laid 115 eggs without stopping. I think I can go him one better. My mother had a turkey hen that began laying April 17, 1907, and laid her last egg Nov. 27, same year, making a total of 166 eggs, without attempting to sit, not even after through laying. She was of the Bronze variety. This is no fake, and if necessary I could furnish affidavit to that effect.

M. E. ROBINSON.

Wm. R. Lewis, custodian of the grounds and buildings of the Kansas Agricultural College, has ten hives of bees. The past summer Mr. L. took from one hive 180 pounds of honey. The average product of the ten hives was \$15 worth of honey, or \$150 for the ten hives. He figures the cost of looking after the bees to have been \$10, leaving \$140 clear profit. He devotes a few minutes to the apiary daily. He says the secret of beekeeping, if there is any secret, is to do the few things necessary at the proper time. Put on a super just when it is needed. Know when a swarm is to come out, and be ready with a hive for it. Know how to detect bee diseases and how to combat them. Work carefully and steadily, and don't get excited.

First about the turkeys. Even if the above is very unusual, it reminds us that a strain of egg-producing turkeys (like Leghorns and Indian Runner ducks) is possible, yet, so far as I can learn, there isn't a "turkey ranch" in the whole State of Florida, and at the same time wild turkeys are in the woods, more or less, all over Florida. All the turkeys in the markets for Thanksgiving and Christmas are shipped in from Georgia and further north.

In regard to bees somebody has said that, while the feed bill for all kinds of fowls (especially here in Florida) is a big expense, *bees* "work for nothing and board themselves." This is, to a certain extent, true; but *once in a while* the beekeeper is not only without honey, but may be compelled to buy barrels of sugar to keep his hundreds of colonies from "going dead." The statement from the Kansas Agricultural College is interesting because it is not only authentic, but because it indicates what educated care accomplishes. And, by the way, is it not true that some of our experts *always* get a crop of honey, more or less?

Since writing the above I note the following, which I clip from the *Cleveland Plain Dealer* of Nov. 26:

20,000 TURKEYS TO TROT; LED BY TEXAS GOVERNOR, THANKSGIVING BIRDS WILL PARADE.

CUREO, Tex., Nov. 25.—Twenty thousand Thanksgiving turkeys will "parade" here to-morrow at Cureo's famous turkey-trot celebration which will last three days.

Gov. O. B. Colquitt and staff will lead the procession. Thousands of the turkeys were driven over land many miles, and this afternoon the incessant "gobble" was heard all over the city.

The turkeys will be shipped following the parade. They will go through the streets afoot.

Editorial

EXTRA-YELLOW VS. LEATHERED-COLORED ITALIANS.

ELSEWHERE in this issue, Mr. Penn G. Snyder alludes to the fact that the editor, through these columns, has spoken of Golden bees as being very often cross and short-lived. We do not mean to claim that *all* extra-yellow bees are bad stingers; but we have obtained stock from all over the United States, and the most of it is either cross or dies off before spring. Many of these so-called five-banders have been bred so much for color that they are about like some of the high-class poultry that has been bred so much for feather that they are practically good for nothing. On the other hand there has been a great demand for the extra-yellow bees. They are beautiful to look at, and are sometimes the equal of any other stock of darker color. If Mr. Snyder has that kind of stock he is to be congratulated. Only recently one of the largest honey-producers in the United States, and a queen-breeder as well, told us he had eliminated all the yellow bees from his yard, adding that he was much disgusted with them on account of their being so cross, and he was going back to the old leather-colored Italians. He and his customers have had some disagreeable experience with his yellow bees, as we happen to know. Notwithstanding he says he bought stock all over the United States, they seem to be very much the same as regards bad temper and impaired vitality.

SHIPPING BEES WITHOUT COMBS, AGAIN; THE GREAT AMOUNT OF INTEREST IN THE PROPOSITION.

LITTLE did we anticipate, when we first advocated shipping bees without combs to save the cost of express charges, and to eliminate bee disease, that so much interest would be manifest on the part of our subscribers. Correspondence is coming in thick and fast from all directions, asking for more particulars—"What kind of cage would you recommend?" "How do you supply the bees with water?" "What is the best food while in transit?" "Could comb-

less bees be shipped by parcels post?" "What effect will parcels post have on express rates on bees?"

Some of these questions we have answered in part. Other questions will be answered more fully as soon as we can secure engravings to illustrate the form of cage.

In the matter of food we use for the present at least the ordinary candy, such as is used in regular queen-cages. But we are coming to the opinion that a thick syrup may be even better. The problem is, however, to provide a receptacle that will feed the syrup to the bees as fast as they require it, *without daubing*. We have tried out the atmospheric feeder using one hole. So far the experiments with the use of syrup have been on so limited a scale that they have hardly warranted us in giving a definite opinion. Water is given to the bees in the same kind of a feeder. Through the top or bottom, rather, is punched a hole about the size of a coarse pin.

Both the cans for holding the syrup or the water, or both, should be secured to the top of the cage. In order to prevent the package from being laid on its side, or being turned upside down (thus causing the feeders to leak) the top is provided with a convenient handle; and, of course, there should be displayed a label, reading "*This side up*."

Through the body of the cage there is secured a series of thin slats arranged horizontally about $\frac{3}{4}$ inch apart and the same distance vertically. These slats taking the place of combs serve the purpose of a support for the bees during transit. Dearly bought experience years ago showed that the mere wire-cloth cage without any clustering supports to hold the bees while in transit would deliver only a small portion of them to their destination in good order. While many of them went through, the use of the slats in lieu of combs has eliminated two-thirds of the former losses while the use of the water-bottle during hot weather has served to eliminate the remaining loss not taken care of by the slats.

It is important that these cages be made light and stout—capable of standing rough usage, and to that end they should be well braced, and only a strong light *galvanized* wire cloth should be used. The latter should be further protected by a wooden grating to prevent making holes through it.

We do not know whether these cages can be sent by parcels post. We advise against it for the present, or until this method of sending bees by express has been developed a little further. The express companies will doubtless reduce their rates on bees so that they will be level with those for parcels post. As the express companies have always met postal rates before, we assume they will do it again. Furthermore, we do not know whether Uncle Sam will accept pound packages of bees in the mails. We believe, however, that the time will come when bees can be sent by parcel post. The only fear we have at present is that some beginner or ignoramus, not realizing what he is doing, may attempt to ship three or four pounds by mail in a package so frail that it will let the bees loose in transit, resulting in a ruling barring bees from the privileges of parcel post. When we have developed a package that will prove to be a perfect success for expressage, then it will be time enough to try for the new postal privilege.

The obvious advantage of sending bees without combs across the country is so great that there will doubtless be a big traffic in the near future. Arrangements are now being perfected whereby bees can be shipped from the South to make up for death losses in the North early in the spring. Due announcements will be given in our advertising columns, with statement of prices, so that the beekeeper of the North, desiring bees to let loose on empty combs where his bees have died, will know just what it will cost to make a new start.

THE IMPORTANCE OF WINDBREAKS FOR OUTDOOR WINTERED BEES.

THE reader's attention is called to an excellent article by Mr. A. J. Halter, in this issue, page 55, on the subject of windbreaks. It will bear careful reading because it strikes at one of the basic principles of successful outdoor wintering.

We are coming more and more to believe that, while double walls and packing are important for outdoor-wintered bees, suitable windbreaks, or something to break the force of a clean sweep of the wind, are equally important. We have known excellent wintering in single-walled hives that

were well sheltered by buildings and shrubbery. We have known of poor wintering in double-walled hives, subject to exposure to the prevailing winds, especially when the entrances faced those winds. Just notice how the dumb animals in the blast of an on-sweep of wind will turn their backs to the wind. The dogs of the polar regions, that will stand more cold, perhaps, than any other living things, have heavy bushy tails; and when not in motion they will stand with their backs to the wind, and the aforesaid bushy tails afforded them a protection that is invaluable. Similarly we have noticed that hives with their backs to the wind will winter better than those facing it; and invariably we find that those in the exposed portions of the apiary will suffer much more than those sheltered by shrubbery, trees, or buildings. Last winter gave us some examples of "deadly parallels." At our Clark yard were some hives upon a knoll facing a half-mile strip of free country. In the same yard were other hives located in low ground among low-spreading apple-trees and brier bushes. The last named came through in fairly good order, while the first mentioned were practically all dead by the first of March. We found the same "deadly parallel" at our other yards. At our home yard there was a bunch of colonies just in front of an opening through the evergreens facing north. These bees nearly all died, or were so weak that they might as well have been dead. Those back of the evergreens, especially in the lower portions of the apiary, wintered in very much better condition. If the reader will turn to the cover page of our Dec. 15th issue, he will see the kind of evergreen for windbreaks which we have found to be most satisfactory. They "do the business."

This winter, for the purpose of experiment, we left one apiary, the waterworks yard, on a high knoll, where it had been all summer, with a windsweep from the north-west, west, and southwest, with practically a mile of almost free country. When we located that apiary, we did not intend to leave it at that location all winter; but late in the fall we thought we would try it out for a few weeks to determine how the bees would stand this exposure of wind. They were all in our latest double-walled packed hives; but in spite of this protection we noticed in the month of December that some of the bees were beginning to dwindle, and that they were using stores faster than the bees of the other yards sheltered by windbreaks.

Our Brunswick yard was located about 9

miles to the north. It was on a sort of side hill, but so situated that it could get a strong windsweep from the south and north-east. These bees were packed in winter cases—cases that ordinarily have given us good results. But as in the waterworks apiary we found the bees were beginning to dwindle, showing that they too were suffering. It became necessary, therefore, to move both yards of bees home and put them in the cellar. This was done on sleds in the snow. How this was done will be fully explained later.

Now, then, let us take a look at the bees at the other yards, packed in precisely the same way—double-walled hives, no better nor stronger in the fall than those at the waterworks and Brunswick yards, but well protected by windbreaks of woods and shrubbery. Presto! we found an entirely different condition. One such yard is located in the midst of woods. Another apiary, next to our factory, is surrounded by tall evergreens shown on the front cover of our Dec. 15th issue. Another yard, the Harrington, is located in an orchard with low shrubbery and apple trees on the north; a piece of woods on the west, apple trees and shrubbery on the south. All the apiaries had an equal and a fair chance. All were well fed up for winter, and all were equally well housed. As already reported, the two yards that we left out in the open, subject to windsweeps, were losing bees and stores; those that were sheltered from the wind were in excellent condition.

We have never had any difficulty in wintering bees outdoors when placed in double-walled hives properly protected with windbreaks, except in extraordinarily cold weather such as we had a year ago; and as these very cold winters come only once in about thirty or forty years it is hardly worth while to take them into serious account; and when they do come, the bees should all be put indoors in the cellar.

If the reader of these lines discovers that his bees are exposed he can very easily move them, if cold weather has set in in his locality, to a more sheltered location. We recently moved a yard of 90 colonies about 1000 feet to the west on a sled. On the north and west is a big mass of woods. On the east side of it is a grove of basswoods. On the south is a slight knoll and some low shrubbery. The most perfect windbreak that we know of is an open spot inside of a piece of woods. A mass of undergrowth consisting of brier bushes and low-spreading trees we would place next, providing they surround the apiary, or at least are on the sides from which the prevailing

winds come. Farm and out buildings make an excellent protection.

We have come to attach less importance to a high board fence on the north and west than we formerly did. The trouble is, the wind strikes it, glances upward, when it is struck by the on-impelling blast overhead, and then glances downward. At our basswood apiary from which we have just removed 90 colonies to a more sheltered location, we found there was one row of hives where the bees would die more than anywhere else in the apiary. The drifting snow shows how the wind would strike those hives and then rebound, apparently, and skip the other rows, which would winter better.

The objection might be raised that bees, if put in an inclosure of woods, will wear out their wings in flying through the brush or trees. To a certain extent this is true; but the most of them will ascend almost vertically until they reach a height sufficient to clear the obstruction. In doing this they clear all domestic animals in the fields near by, thus avoiding trouble with neighbors. When an apiary is located near a line fence next to an open field the bees are apt to fly in such droves that they are liable to attack the farmer and his horses in plowing, cultivating, or in haying and harvesting. We have, therefore, come to the conclusion that all apiaries should be located, as far as practicable, remote from a line fence, and so inclosed that the bees will have to fly high, where they will not bump up against live stock in great droves. When they descend they will be so scattered that they will prove to be no menace to either man or beast.

We shall be glad to hear from some of our subscribers and correspondents, because we believe that a thorough discussion of this matter of windbreaks will show their very great importance. While they have little or nothing to do with bees wintered in cellars, we should remember that probably only about a tenth of the bees in the country are housed indoors during winter.

We are also pretty well convinced that this matter of windbreaks is of supreme importance to beekeepers located in the southern States. If there is a place where one suffers from cold it is in a semi-tropical climate during winter. The atmosphere is chilly and damp—so disagreeably cold that it seems to go clear through one's anatomy. We are convinced that damp chilly weather is about as destructive to bee life in the South as the cold dry weather in the North. In fact, for our own comfort we would prefer the latter.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

CHARLES S. SHARP, feeding dry cube sugar, p. 30, is a fine thing in some cases, *with* the proper moisture; but I'm afraid the beginner can not count on that moisture in all cases without supplying it.

P. C. CHADWICK, I don't know about your locality. May be, as you say, p. 5, it takes a lot of bees to defend large entrances, but here, in the height of storing, I've some doubt whether any bees lose time merely as guards. At any rate, I believe a larger force is needed for ventilation with a small entrance than for defense with a large entrance.

A. I. ROOT, you say, p. 36, "Is it not true that some of our experts *always* get a crop of honey more or less?" While an expert might get a crop where a bungler would fail, it might be nearer the mark to say there are *localities* where there is always a crop. If there is no honey in the flowers there will be no crop, expert or no expert, and there might be a locality always so good that even a bungler could never fail.

MORLEY PETTIT, referring to a Straw, p. 754, in which I say, "European would have to be pretty bad if you couldn't find two healthy combs in every diseased colony, at least that is the case in this locality," replies, "In the locality of Ontario you would have to put the word American instead of European in that sentence. When we find European foul brood in one or two colonies of an apiary, we can rest assured that we do not need to go any further, for it is practically certain to be in every colony in the apiary, and in every brood-comb. I suppose the fact that it is found mostly in apiaries of black bees makes it so much worse with us." Thanks for that much more light, Bro. Pettit, even though the darkness be yet somewhat profound. [This is a surprising statement concerning European foul brood. We have never had any experience with it, we are glad to say. We should like to inquire whether others have had the same experience.—Ed.]

"We have not yet seen the cellar where the ventilation was as good as outdoors," p. 790. Strictly speaking, no. Yet if you'll go down cellar with me, Mr. Editor, I think you'll agree that the difference is not recognizable. At this present moment, with 37 degrees outdoors and 53 degrees in cellar, the door is wide open. When cold enough to close or partly close it so as to keep up to 45 degrees, the difference outside and in

makes a rapid change of air so that it is always pure. [Those who recommend outdoor sleeping-porches for the treatment of tuberculosis claim that there is a big difference between porches and a ventilated room inside of the house. If there is any thing in this, the quality of the air outdoors is very much purer and better than that inside of a building that receives its air through a door. Relatively, however, the difference may not be so great. But there is one thing sure, doctor, we do not believe you would run the risk of dropping your cellar temperature to, say, the freezing-point, 32 Fahrenheit, within your cellar; and yet it is conceded that outdoor bees will stand the freezing-point very nicely, and come out in fine condition the following spring. They will stand all grades of temperature, providing it does not go below ten above and continue there too long.—Ed.]

NOT often are two such interesting articles brought out as in the friendly Lovell-Ryan controversy, pages 654 and 771. As a beekeeper of the rank and file, I should incline to the opinion that bees may be attracted by the odor of honey where color can play no possible part, and also that color plays even a more important part than odor when it comes to bees and flowers. But more interesting to me than this is the Crane-Ryan item. Mr. Ryan says, "It seems rather out of the way to speak of the Man-God as learning any thing from the hills and valleys, flowers, etc.: If I mistake not, he was invested with all human science, and had naught to learn from his own creatures." Surely reason would point in that direction. Of him it is said, "All things were made by him; and without him was not any thing made that was made." And is it reasonable to believe that he would learn from the objects of his creation? Plainly Bro. Crane is following something else than reason. And I must confess sympathy with his view. I like to think of the Savior of men as very God in the highest and fullest sense of the word, and yet at the same time, in some mysterious way that I do not pretend to understand, as being a man just as much as I am a man, who had to learn things just as I have had to learn them. Moreover, if Bro. Crane has no reason for his comforting belief, he has something higher than human reason; he has the word of God, which says, "And Jesus increased in wisdom."—LUKE 2:52.

SIFTINGS

J. E. CRANE, Middlebury, Vt.

In the discussion of cases and carriers, p. 683, Nov. 1, there is this to be said: That honey needs much more careful packing to go safely in cool or cold weather than when the temperature is up to about 70 degrees.

* * *

The bulletin recently issued by the Department of Agriculture on the management of bees for the prevention of swarming and securing surplus comb honey is, I believe, one of the best things we have along this line. Every beekeeper should secure a copy.

* * *

Mr. Doolittle's advice, p. 687, Nov. 1, about selling the year's honey crop, is certainly orthodox, and all right for the beekeeper without much experience; but the season is longer than formerly, and we have calls now for comb honey from July till March.

* * *

The reason why that swarm hung on a limb all the fall without building any comb, p. 743, Nov. 15, is not at all strange. It was, doubtless, because no honey was coming in. Bees swarm in some parts of Florida before the flowers yield honey, and I found last spring that it was impossible to get new swarms even to draw out foundation unless the bees were fed.

* * *

Mr. Doolittle's advice, page 723, is all right for hives with sealed covers; but where there are absorbent cushions that will allow the moisture to escape above, it seems to me quite too much ventilation to give. If we ventilated our sitting-room as much in proportion to its size it would make an opening across one end and four feet high, or about 65 square feet.

* * *

That editorial, page 717, Nov. 15, on the difference between the flavor of comb and extracted honey, is right to the point, and covers very fully the ground of putting up extracted honey. I can only add that every time honey is liquefied it seems to lose more and more of its original flavor, until, if repeated many times, it becomes only a soggy mass of sweetness.

* * *

The parcels post seems likely to prove a blessing to beekeepers as well as to the rest of mankind. This reminds me that I recently received by mail a section of comb honey from Paul Hunten, of Somerset, Col-

orado, without any breakage or leakage. The section was as handsome as the honey it held, and was simply enclosed in a corrugated paper carton; but the section was a special kind as described on page 732, Nov. 15, and well adapted to being shipped in this way.

* * *

Mr. Byer's experience with black Italian bees in a new yard is of general interest. I used to think that a black colony was hardly worth wintering; but of late years I find I can get almost as much surplus from blacks as from Italians, and I sometimes wonder whether the blacks have improved or whether the Italians have degenerated. I think more difference will be seen between the two kinds in a poor season than in a good one, and this may account for the great difference experienced by Mr. Byer.

* * *

The house apiary shown on the cover page for Nov. 1 certainly looks well. I have run across two or three in inspecting. There are some points in their favor, such as the lessened danger of stings and a chance to work in all kinds of weather. But on the other hand, the inconvenience and loss of light more than balance the advantages, to say nothing of the greater expense and loss of queens.

* * *

Major Shallard, p. 701, Nov. 1, gives some facts about bee paralysis that interested me greatly. I had the care of some bees last March where the disease existed, and I studied it from day to day. My first impressions were that the disease is caused by some kind of poison, and I found it hard to think otherwise. But why should but two or three colonies in a yard be diseased? I have found in two or three instances that a single colony of bees would gather honey in quite a different manner from any other in the same yard. These bees would either go further or would work on sources that other colonies would reject. Major Shallard's statements that some localities were much more subject to the disease than others would seem to confirm the idea of poison. Poison, I learned, was being used in the vicinity of the colonies which I just mentioned. The poison, I also learned, was often mixed with honey when used. Very much more study of the subject, however, will be necessary before I can assert positively or with much certainty that I am right.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

REPORT OF 23D ANNUAL CONVENTION.

The 23d annual convention of the California State Beekeepers' Association was held on Dec. 12, 13, 14, at the Y. M. C. A. building, Los Angeles. It would be impossible to give a report of the three days' session in detail. I will, therefore, mention briefly some of the most important points. Nearly all of the great honey-producing counties were represented. Many new faces were seen. Men from north and south worked side by side for results. No one man won more esteem than Willis Lynch, of Newman. C. Hauser, of Sacramento, and J. G. Gilstrap, of Ceres, were also strong factors in the convention. All were new to the annual assembly.

In many respects it was the most successful meeting ever held by this organization, the most pleasing features being that harmony prevailed, and that advancements were made on foul-brood legislation, so long hoped for. The bill is now ready to present to the State legislature, and has the solid support of the entire beekeeping fraternity. It is to be hoped we may be able to convince our representatives at Sacramento that they should pass it in the interest of this important branch of agriculture, for I think it is without doubt the most complete bill of its kind ever drafted for the protection of the beekeeping industry.

Mr. J. D. Bixby's remarks on black brood were eagerly listened to, for there is no question at the present time that is agitating the minds of the beekeepers of California so much as that of eradicating black brood or being able to combat it.

Mr. J. E. Plesants, of Orange County, had a very interesting paper entitled "Ridding a County of Foul Brood." This venerable gentleman told how he had in ten years reduced American foul brood from 15 per cent to $\frac{1}{2}$ of one per cent, which is a record well worth being proud of.

The paper of Mr. A. F. Wagner, of Imperial County, entitled "County Ordinances and their Value," created much discussion, and showed plainly the opposition to drastic county ordinances, but doubtless helped to crystallize opinions favorable to our proposed State law.

Prof. A. B. Ulrey, of the University of Southern California, spoke on "The Principles of Breeding."

Prof. Ralph Benton, of the same institution, spoke on "The Varieties of Bees as Nature Left Them," which was largely geographical in nature, describing the lo-

cation of different races and the surroundings that limited their natural distribution.

Then came two fine papers on queen-rearing, by Mr. Henry Perkins, of Artesia, and Mr. Geo. J. Brown, of Tusten. Both are young men, and have a great future in prospect.

At the evening session Dr. C. A. Jenks gave a very interesting demonstrative lecture on "First Aid to the Injured." While this was not on a subject in connection with the bee industry, yet it was valuable for its instructions as to what to do in case of emergencies. The most valuable part to the beekeeper was that relative to snake-bites, for there are few apiaries that do not have the rattlesnake as a visitor.

Willis Lynch, who has traveled around the world observing the different races of bees, told of bees as he found them in Hawaii, the Philippines, Borneo, India, Egypt, Italy, France, Germany, and England. His description of the large bee of the Philippines, as well as the smaller, was especially interesting, as well as how the natives of Borneo feast on the unhatched brood, preferring it to the honey.

Mr. C. Hauser's remarks on organization were timely and to the point, and deserve a place on the records of our association.

Of Mr. J. G. Gilstrap, I can say nothing better than that he came to work, and helped accomplish many of the advancements of the convention.

Mr. J. B. Neff, who conducted our beekeepers' institutes so successfully during the past summer, spoke on co-operation. Mr. Neff is in the Walnut Growers' Association, and knows the value of co-operation.

The association passed a resolution inviting the National to come to California in 1915. This developed a scramble between San Diego and San Francisco for a place of meeting, which was finally disposed of by leaving the decision to the National.

Riverside County presented a resolution adopted by that county's club relative to protecting the bee-ranges from brush fires. They have asked their county supervisors to appropriate a fund for fighting such fires, and to prosecute persons who carelessly start fires. I was especially glad that this action was taken, for I know of nothing that is more detrimental to the beekeepers of the sage-range country than to have their honey source destroyed.

Suitable resolutions were adopted in

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

THE SCHOLL IMPROVED HIVE-NUMBERS.

The accompanying illustrations will give a very good idea of the hive-numbers of my own design which I have used for a number of years. Though everlasting they are easy to make for any style of hive in use, quickly interchangeable from one part of a hive to another, or from hive to hive. No nails, staples, nor any thing of the kind are necessary to hold them in place; and in this way they overcome the greatest objection to practically all the hive-numbers so far invented. This advantage is especially

from one to another in case the hives are interchanged or changed end for end. They are easily made by simply cutting pieces of galvanized iron $2\frac{1}{2} \times 3$ inches, snipping off the two upper corners, as indicated, and then bending over the ends to hang over the upper edges of the hives. They are easily bent or folded over in any common bench-vise. By means of a small piece of hard wood the exact width of the upper edge of the hive in use, clamped in the vise, a gauge for each number-tag is obtained that insures all being folded alike.

FIG. 1.—Scholl improved hive-numbers, showing how the galvanized iron is folded and adapted to various styles of hives.

FIG. 2.—Numbers for the rubber stamps; simple, plain, and bold, hence easily read.

marked when hives are composed of many shallow stories, as with our divisible-brood-chamber hives. Then, too, in the old system of numbering it is a nuisance and expense to keep nails, staples, or hooks in proper repair, on each end of every deep hive-body or shallow story. I say on each end of every hive or story, because it becomes necessary to change the numbers

They are easily numbered by using a set of only nine numbers, as shown in Fig. 2. It will be observed that only one stamp is necessary for the 6 and 9, as the former can be reversed to print the latter. A simple home-made cotton pad can be supplied, covering the cotton batting with a piece of thin domestic. I used good solid black coach paint, and find that it lasts admirably. Of

Conversations with Doolittle

At Borodino, New York.

FEEDING BACK FOR COMB HONEY PRODUCTION.

As the price of comb honey is much more per pound than that of extracted, I have been wondering whether I could not extract my honey next summer as I have usually done, and then, instead of selling it, feed it back to the bees and have them put it in sections. What do you think of this?

Feeding back extracted honey for the purpose of producing comb honey is something which has been often tried and frequently written about; but so many conditions enter into the problem that many of our most skillful apiarists have very nearly if not quite failed of success. From my own experience, and from what I have been able to learn from others, the character of the bees that are used is among the first in importance. If my experience proves any thing it is this: No financial success can be obtained with bees which are prone to store their honey close up to the brood in the brood-nest. Any variety of bees whose disposition is to cling to the brood-chamber, to crowd it with honey, and, when that affords no more room, to cease labor rather than to overcome the disinclination to pass beyond the limits of the brood-nest into a surplus apartment above, can not be successfully used in this plan of feeding back. In fact, such bees are hardly profitable for section honey, even though they may prove the very best to the one whose apiary is run for extracted honey. In selecting bees to be used for feeding back, no point is more important than that those should be chosen which are willing to enter and work in supers or sections quite distantly removed from the brood. The dark or leather-colored Italians, which prove to be the very best for extracted honey, are very defective in this respect, and they also give their cappings a dark greasy appearance by their plastering the scanty amount of wax used right down upon the honey. These bees can not be profitably used for section honey, to say nothing about comb honey produced from honey fed back. Carniolans, golden Italians, the German race, or crosses, in which black brood predominates, are superior for your purpose; though even among these, judicious selections may be made to a great advantage.

Then nearly if not of equal value with the character of the bees comes the character of the queen. The point to be looked after here is that the queen should be of such a make-up that she will have her hive well supplied with brood at the end of the honey-flow, when we wish to begin feeding

back the honey we have extracted during the flow. It is not so necessary that she continue her prolificness after the feeding has begun, more than enough to keep the colony in good condition for winter; but unless she has a hive pretty well filled with brood in all stages, when the feeding should commence, the colony will not have the numerical strength desirable, and there will not be enough brood in the combs to furnish the required reinforcements, as the work progresses and the old bees perish, in which case the finishing-up of the matter will result in failure, no matter how "rosy" the outlook at the start.

Next in importance comes the time for the white-honey flow in your locality. If the flow continues till late in the season, it is little use to try feeding back at all. If we can commence feeding comparatively early in the season we shall avoid, as far as possible, the disposition of the bees to store honey in the brood-chamber—a disposition which, with all varieties of bees, increases as the season wanes. Then we secure the great advantage of having the work done during the hottest weather, at which time bees produce wax and build comb with more economy than is possible after the nights become longer and colder. If we attempt feeding back before the harvest of white honey closes we shall lose all the bees would store without making a proportionate gain. In this locality the opportune time is immediately at the close of the basswood flow, about July 12 to 16, in the interim between this and the yield from buckwheat, which commences about August 15 to 20.

Lastly, we have the size of the brood-chamber. This, of necessity, should be small, otherwise room is given for the storage of a large amount of the honey fed, in which case this honey is of less value than was the case before we commenced operations. Then with a large amount of comb an opportunity is furnished for the production of an immense amount of brood whose value beyond a certain limit can not be great, and such brood means the consumption of a very large amount of the honey fed. I have had better success with a brood-chamber of about the capacity of five Langstroth frames than with one either larger or smaller; and by selecting such well filled with brood, the larger part of which is in the egg and larval form, a seeming advantage is gained.

General Correspondence

THE IMPORTANCE OF KNOWING YOUR LOCATION

How the Absence of Pollen in the Breeding Season in the Spring May Ruin a Whole Apiary

BY A. B. MARCHANT

For the past fifteen years I have been keeping bees for profit. I have kept from 500 to 1000 colonies in three yards, running mainly for extracted honey, having shipped as much as 50 tons in one season. I have always reared my own queens, and the past two seasons I have gone into commercial queen-rearing, which has led to the discovery I am now writing about.

Last March The A. I. Root Company contracted with me for a carload of three-frame nuclei and a carload of ten-frame-hive colonies of bees. I knew this was a big undertaking; but, as the bees were not to be shipped until I had gathered the season's crop it seemed to me there would be a good profit in it. I accordingly made preparations to ship them; but before I made either shipment I had young laying queens ready to take the place of those that were shipped with the order. The hives from which I shipped those bees were left with about a three-frame nucleus. I immediately gave each a laying queen and began feeding to start brood-rearing. I then left the bees with my helper, and was gone for over a month, expecting to come back and find them in fine order, when, to my surprise, I found about one hundred dead and swarmed out. Upon investigation I found that the bees were destroying the eggs as fast as the queens could lay them.

I saw at once that something would have to be done immediately. I examined all apiaries near me, and found the bees weak, and queens not laying, on account of no pollen coming in. I have always known that my locality is short on pollen after the honey flow is over; but I had no idea it was as bad as this. So I decided the only chance for me was to buy bees and strengthen what I had left. So I began to look out for bees. Many times I have heard the beekeepers 15 miles south of me say they had swarms in February and March, and plenty of brood up till November; so I at once called on some of these men, and examined their apiaries. I found their bees in fine condition. I purchased one yard with 65 colonies and borrowed 50 from another beekeeper, and began to give out the brood to my weak ones. I had been in the business for fifteen years, and for the last ten years

I well knew that pollen was my difficulty in getting my bees strong in time for the honey-flow. I also knew that the beekeepers south of me built their bees up earlier than I did; but on account of my location being better for honey than those south of me I paid no attention to them.

After all these years I have found what I have needed in my own locality, and a way to get it. I am now moving my bees to these locations, and will keep them there until the first of April, when the tupelo bloom is open, then move to my present location and stay till June 1, then move back and stay till next April. In this way I can get a crop of tupelo honey, build my bees up for winter, and at the same time have an ideal place for queen-rearing and the shipping of bees by the pound, and nuclei of any size. This location I purchased with the 65 colonies. The owner tells me that he has drones flying in February and sometimes has swarms during the same month.

This place is located on an island; and, with the exception of one small apiary, it is five miles from any other bees; so it is a fine place for queen-rearing and pure mating of bees.

Sometimes it pays one to get into trouble. In this case I believe it will pay me. It goes to show it pays one to study his location and find out where the trouble is, and then try to overcome it.

Sumatra, Fla.

A NEW CURE FOR BEE PARALYSIS

A Disease Resembling Bee Paralysis Relieved by Feeding Syrup Containing a Physic

BY W. A. BARSTOW

Some may laugh at the strange treatment that I gave my bees when they were sick, but nevertheless my plan was a success. The bees in one of my colonies were dying in large numbers, their abdomens being unusually large; and when I picked them up in my hands a slight pressure would cause them to excrete a large amount of yellow liquid, which, when dry, looked like pollen. The bees trembled as though in distress, and it occurred to me that the intestines might be clogged.

My theory is this: When plenty of honey is coming in, the bees may show no sign of sickness; but later in the summer or fall the bees may get some honey containing pollen that might be poisonous, or that has soured, or grown moldy to a certain extent; so that, when they feed on it, it is in the

right condition to cause what might be called constipation. At any rate, if there is no relief the bees die in great agony. In this condition they crawl out of the hive with their wings stretched out or lying close to the floor, and they roll over and tremble, and at times seem to lose control of themselves. They have a greasy appearance, and their abdomens seem to be so distended that the different segments hardly meet. They go to the edge of the alighting-board, and fall to the ground in great numbers and die.

I am not a doctor nor a medicine man, nor even an expert beekeeper; but I decided to try a remedy that occurred to me. I made a syrup of equal parts of sugar and water, and then mixed with it about a fourth of a teaspoonful of *herbine*, a medicine which we get here at the drugstore. I poured some of this syrup into an empty comb and set it at one side of the hive, and the bees quickly emptied the cells. The next day the hive was fairly covered with brown spots, and one would almost need an umbrella in the apiary, for the medicine took quick action. I suppose almost any kind of strong physic would answer, but the *herbine* is all that I happened to be able to get.

Later on, the bees in this colony were sick again, and I tried feeding syrup alone, but it had no effect. Then I added the medicine, and it worked as well as before.

Two more colonies were diseased, and I gave the bees the same treatment and with the same result.

My colonies are all right now; but if I have any trouble I intend to shake the bees on empty combs and give them a new supply of medicated syrup to take the place of any bad stores they might have had.

San Jose, Cal.

[This looks like a case of bee paralysis. If so it might not disappear of itself without treatment. Was the medicine responsible for the cure of the trouble mentioned? We should be glad to have others try it and report.—Ed.]

THE ADULTERATION OF HONEY, AND WHAT IT MEANS TO THE BEEKEEPER AND DEALER

BY HENRY REDDERT

Up to a decade ago, before our national Government enacted the pure-food laws now in force, widely distributed eatables of all kinds, including honey, were found adulterated to some degree. It was said at one

time that 40 per cent of the honey sold in Ohio alone was mixed with ingredients foreign to its own kind. We know of cases where small dealers, eager to make the most money out of a given quantity, mixed it with sugar syrup the moment the farmer selling it left their store. But the practice has been abandoned, so far as we know, simply because they fear the sting of prosecution.

Large dealers, as a rule, were honest. If not, their business lasted but a short time. It was the small consumer who suffered most, the large buyers having skilled inspectors at their warehouses—a fact known by the sellers. I remember when honey that was purchased from any one excepting the beekeeper was considered impure, even if the dealer guaranteed it. Even up to the present day this supposition is still found, but mostly among people who know very little about honey. Recently a lady said to me, "I buy your honey because you have bees." I told her that I knew dealers in the city who also had pure honey, but she still insisted that the beekeeper's honey was better.

Frequently we read an article in the daily newspapers about artificial comb honey, colored and mixed strained honey, sugar syrup, etc. All have their share of condemnation. One year my son sold the larger part of my crop to druggists in one city. The honey was very light. He had solicited their orders by a small sample in a clear white-glass bottle. One refused to take the gallon he had ordered, saying it was colored, because the density of the honey in the tin bucket didn't admit the clear and light color of the sample. Of course, he should have known better. This case shows that even men of science are baffled as to the purity of honey.

A beekeeping friend relates this incident: A grocery and daily-market owner bought a quantity of his honey for his own table, saying, "When I buy your honey I know it's pure." My friend replied, "What's the matter with the honey you sell?" He answered in broken English, "Dey always put a little in."

Why is the consuming public so doubtful? Simply this—even now we have beekeepers and honey-dealers who believe they have found a recipe to improve the color and taste of their product. Every purveyor of honey should bear in mind that the education of the general public in the elaborate use of honey instead of other syrups depends largely on the purity of the article. By all means, don't mix. Every now and then the newspapers cite cases where this or that firm or person has been fined for

violation of the pure-food act. Let us conduct our business in such a manner that every consumer will be thoroughly convinced the honey he eats is pure, whether purchased from a dealer or beekeeper. In the long run, honesty is always the best policy. Cincinnati, O., Dec. 8.

BEEKEEPING IN CALIFORNIA

BY P. C. CHADWICK

Continued from page 42.

memory of prominent beekeepers and members of the association whom death has claimed during the past year.

Mr. W. H. Allen, of Ventura, asked that the report that Mr. Corey brought the first bees to California be corrected, as Mr. Corey never claimed that honor. Mr. Harbison shipped the first bees to the State that we have record of, but said he found others here when he arrived. Mr. K. M. Henneken, of Monterey, said that the Spanish fathers had a record of bees having been brought here some time during 1700.

The annual election of officers resulted in President Farrer and Secretary Shaffner being re-elected to their respective offices. J. G. Gilstrap, of Ceres, succeeds Ralph Benton on the executive committee.

Action was taken looking to the establishment of a bee journal for the association.

* * *

NOTES FROM THE CONVENTION.

J. D. Bixby condemned old combs as being detrimental to beekeepers when fighting black brood. This position was also taken by W. G. Hoore.

* * *

Owing to sickness, Geo. L. Emerson was not seen after the first day's session. Mr. Emerson is one of our old war horses, and that he was missed goes without saying.

* * *

Mr. C. Hauser, of Sacramento, had some honey from carpet grass (*Lippia nodiflora*) at the convention. It is a beautiful white in color, and has about the mildest flavor of any I have ever tasted.

* * *

Mr. K. M. Henneken, of Monterey County, told of a colony of bees that produced honey to the value of \$38.00 in a single season. This gentleman was inviting beekeepers to come to his county with bees to help save the wasting nectar. It really seemed strange to have a man asking beekeepers to come with him instead of sending them word that there was a foul-brood fence up to keep them from sending bees in from

any locality within twenty-five miles of some other place.

* * *

Spraying black-brood combs with strong brine and allowing the salt to crust thereon until ready to use to protect from moth and kill disease germs was a plan spoken of by Mr. Bixby. Although he lays no claim to having originated the idea, it is said to work successfully. The combs are dipped into the water in order to remove the salt before being used again.

* * *

A word of praise to the deserving is never amiss, so I say that, when President J. W. Farrer and Secretary A. B. Shaffner were unanimously re-elected to their respective offices, their efforts of the past year were recognized.

Sec. Shaffner during the past year has written more than 600 letters, and has addressed thousands of reports and bulletins, for which he would not even accept the meager \$25.00 which was his by virtue of his office.

* * *

Colorado claims to have 27,000 colonies of bees. Los Angeles County, Cal., is said to have 60,000; Imperial County, 12,000, and from the best information at hand I feel safe in saying that there are 250,000 colonies south of the Te hatchapi. No wonder beekeepers complain of being a little crowded in places. I have no figures on the number in the San Joaquin and Sacramento valleys or the upper coast country; but that California has "some bees" is a foregone conclusion, and there are thousands of colonies in the State that never figured in the last census.

* * *

As a matter of information to the California beekeepers I wish to say that our exhibit at both the San Diego and San Francisco fairs in 1915 will be under the supervision of Mr. M. H. Mendleson, of Ventura. The writer will be Mr. Mendleson's secretary, with H. J. Warr, of Perris, in close touch. I wish I could impress upon the California beekeepers the necessity of beginning now for this exhibit. We have an opportunity before us to astound the world with the grandest exhibit of our products ever seen. We must have money, honey, and nice wax in just as liberal quantities as we can afford. We want as many kinds as California produces of as near pure honey of its kind as can be secured. Brother beekeepers, this will doubtless be the last time in the lifetime of at least the older of us to see our industry crowned

with an exhibit that will show to the world that we are able to grasp an opportunity presented at our door. Every beekeeper in California could set aside at least one case of honey or the proceeds from a case to help with the exhibit. We also must have the finest of comb honey in liberal quantities. Begin your plans now for helping to make it a grand success, for it will be a monument not only to our industry but to the State as well.

* * *

During convention time I busied myself talking with members regarding the flora of various parts of the State, and the quality of honey produced from different flowers. I was especially anxious to learn, if possible, whether alfalfa produced different colors of honey in different regions, or whether the difference in color is due to the mixing of darker grades with the alfalfa. I have always doubted the claim of some that it produced different colors in different soils. The opinions of those I questioned were about evenly divided, but several to whom I spoke were emphatic in saying that it is other darker grades mixed in the alfalfa that give it the darker color, so until I have stronger evidence on the question I will remain of the opinion that it is no more inclined to do so than is the button sage, the orange, carpet grass, or any other of our forage plants.

A NEW PLAN FOR REQUEENING

Allowing Queenless Bees from a Strong Colony to Unite Slowly with a Nucleus Containing the Young Queen

BY A. V. SMALL

It is often desirable to requeen a good many colonies late in August or early in September—first, because the apiarist has more time to give to queen-rearing at that season; and, second, because the August-reared queens usually prove vigorous layers the following year. But at such a time as this, when the best of the smartweed is gone, and there is a hint of fall in the air, the bees sometimes refuse to accept a queen introduced by the ordinary cage plan; also some colonies are very irritable when the late honey-flow tapers off; and to hunt for queens when bees are cross is a disagreeable job.

The following plan is original with me; and while I have used it only one season the results have been very satisfactory: My queers are mated in nuclei of from two to five full-depth frames. After the young

queen has begun to lay, and some of the larvæ have hatched, I lift out one or more of the frames with brood, adhering bees, and the queen, and place them in a hive-body on the stand of the hive I want to requeen, putting over it a screen with a spool plugged with queen-cage candy tacked to the under side of the center of the screen, where there is a hole the same size as the hole in the spool. On this I put an empty brood-chamber with a feeder of thin syrup. This I cover with a bee-escape board, and finally I set on the full colony that is to be requeened. This is done in the evening after the bees have stopped flying.

The next morning, when the bees of the full colony pass down through the bee-escape, they find themselves with a feeder of thin syrup in the empty hive-body, separated from the full colony and old queen by the escape-board above, and from the nucleus below, containing the brood and young laying queen, by the screen wire with the candy spool. In this queenless, broodless, combless condition they realize that there is something wrong. They have lost their old home and their old queen. By the time they have eaten their way through the candy spool they are fairly crying for a new queen, and are more than willing to unite with the nucleus. The strong point in this plan is that the bees are made to feel the desire for and the need of a queen; also notice that this large force of bees from the old colony is composed of the strangers, and that the little nucleus force is at home in the sense of possession.

In a day or two the old colony on top will have only a few bees, and the old queen can be found easily, and removed, after which the combs and what bees are on them may be put in the lower hive, the two empty hive-bodies removed, and the work is done. One colony that was requeened by this plan had been queenless for nearly three weeks. No fertile workers, however, had appeared. I should like very much to try this on a colony that did have laying workers.

At a time when there is no honey to gather, and the bees are loafing instead of going to the field, they are slow to pass through the escape. At such times they can usually be induced to pass the bee-escape, in an attempt to go to the field, by placing a small feeder of thin syrup in an empty super above the full colony.

From my experience last fall, this plan will work up to the time it is too cold for the bees to pass readily through the bee-escape.

North Topeka, Kans.

FIG. 1.—Robert Stites, of Colorado, preparing his winter cases.

SOME BEEKEEPERS OF COLORADO

BY WESLEY FOSTER

Mr. Robert Stites is one of our newer beekeepers in Colorado; but he is going at the business right, and we expect him to make a success of it, as he already has in the arrangement of a very neat apiary. He lives but one or two miles from Montrose, and his apiary overlooks the Uncompahgre Valley, giving a beautiful view of this rich agricultural and fruit section. We found Mr. Stites at work upon his winter cases, one of which is shown over the first hive in Fig. 1. He lost most of his bees the winter of 1911, and he does not expect to have another like experience if preparation will avoid it. The space between the hive and the outer case he will pack with leaves, chaff, etc. This winter he has packed them

with dried horse manure. An empty super filled with chaff goes on top, and an outside strip goes around the super to cover up the space at the top of the winter case. The bottom-boards are made several inches larger than the hive, so that the winter case will just fit. I do not know whether Mr. Stites plans to bank up around the bottom-board, but I should think that space would be cold for the bees during very cold weather, with only the inch board between them and the outside.

Fig. 2 was taken near Mr. Robert E. Foster's apiary in Montrose County, Colorado. Mr. Foster is standing beside a clump of greasewood. Greasewood is a native of the desert, growing, however, on the lower levels, but rarely found upon the well-drained mesas. It is quite a favorite with the bees, the large yellow clusters of bloom

FIG. 2.—Robert E. Foster standing beside a clump of "greasewood."

attracting them in large numbers. The resemblance to goldenrod is quite marked.

Mr. Foster is apiary inspector for Montrose County, and has done excellent work in reducing the prevalence of foul brood.

Over to the south of Fruita, in Mesa County, Colorado, rise the rocky sides of the mesas. Along the foot of the cliffs flows the Grand River. Sloping gently to the north and east from the river for several miles is some of the best land on the western slope. Apples and peaches are grown by the hundreds of carloads. Alfalfa, sugar beets, and general farming operations are followed by many. Much of the land, however, has become seep land from the application of too much irrigation water or the running of ditches and the application

of water to land lying higher up; and over much of this seep land sweet clover grows, making of this district a valuable honey-producing section.

Mr. F. B. Hill lives about three miles east of Fruita, and has the largest and best conducted apiary I have seen in Colorado. Three long sheds, one of which is shown in the illustration (cover picture for this issue) shade about 120 colonies each. The advantage of these sheds is very apparent if one visits this country in August. The alkali-covered ground reflects the sunlight with a blistering glare. The intense light deceived me, and I over-exposed two films so that they were worthless, and the film this was taken from was so dense it was difficult to get a good print.

FIG. 3.—One of the rows of hives in Mr. Babberger's artistic garden apiary.

FIG. 4.—Panes of glass used as super-covers or honey-boards.

Mr. Hill “flags his queens,” as his hives are so close together in the rows. Different-colored rags are tacked on the fronts of the hives; and red, green, black, etc., spots are painted upon others. A few of the hives have the entire front painted a different color.

Mr. Hill operates his apiary for comb honey in 4 x 5 plain sections, and he secures a beautiful product. He uses shallow extracting-supers early in the season, taking them off and placing them below the brood-chamber when the comb-honey supers are put on. These extracting-supers are left below until fall, when they are removed and put away till spring. They are then put on top full of honey for the bees to use in breeding up. Mr. Hill told me that he sold \$1800 worth of honey this year from his apiary. He operates only his home apiary, having no outyards.

Several months ago I told about the beautiful Canon City fruit district—its sylvan country homes, pretty country lanes, and delightful climate. Now I want to tell you of one of our beekeepers there.

Mr. Babberger is an artist photographer, a fruit-culturist, gardener, and beekeeper. He is a shrub and flower lover, and his little Dutch garden beside his house reminds me of my friend and neighbor Karl Dehn, whose particular passion is dahlias. (I wish you might hear Mr. Dehn pronounce “dahlias” and hear him talk flowers.) Mr. Dehn learned his flower gardening in Berlin; and whether Mr. Babberger gardened

in Berlin I do not know; but his little garden and apiary are worthy of his fatherland.

Mr. Babberger considers his work in the studio far too confining and also too mercenary. People want only cheap pictures, and he does not make that kind. His pictures are worth his price; and when we had our beekeepers meet Dr. Phillips in his studio, Mr. Babberger had his honey piled in the reception room, and he was charging a price commensurate with what he considered it worth. He was asking \$3.50 a case for his comb honey, and was getting it. Some others were selling for \$2.50 and \$2.75; but Mr. Babberger would not sell for such a price.

Probably scores of fruit-growers—neighbors of Mr. Babberger—have stopped when driving past his apiary to admire the white rows of hives between the apple trees, one of which is shown in Fig. 3.

Mr. Babberger harvested 2300 sections of honey from 25 new swarms, and has always counted on ten dollars' worth of honey from each hive. The spraying for the leaf-roller destroyed a good many of his colonies last spring, so that his crop was very small.

If we could have half a dozen beekeepers in each county like Mr. Babberger they would have a wonderful influence in raising the standards of bee culture. Mr. Babberger uses the Danzenbaker hive and 4x5 sections. One of his special hobbies is the use of panes of glass for honey-boards.

He claims for them many advantages, chief of which is the ease of diagnosing the condition of the colony without disturbing the cluster. The glass requires cleaning about every two years. Two hives with the glass in place are shown in Fig. 4.

Boulder, Colo.

BEEKEEPING IN WEST FLORIDA

S. S. Alderman a Progressive Beekeeper for Forty Years

BY J. J. WILDER

This year I had the opportunity of making a 3000-mile tour or ramble visiting beekeepers over the Southeast, and it was my great pleasure to meet some of our old landmarks in beekeeping; and among others were Mr. J. K. Isbell and S. S. Alderman, near Wewahitchka, Fla. Both gave me something of their ripe experience in beekeeping, and Mr. Alderman gave me his photograph and some data regarding his experience. His letter follows:

The first bees I owned were bought in 1872. The apiary was located at the "Old Fort" place, 7 miles from the postoffice now known as Wewahitchka, Calhoun Co., Fla. This embryo apiary of 70 hives was turned over to the care of a young man, J. B. Roberts, who was a natural apiarist, but he knew nothing of the advanced methods of beekeeping. I persuaded him to try new hives, and we worked together for twenty years, during which time we increased the number of hives to 700 at the "Old Fort" place. At this period I began to scatter the apiaries, placing the bees near the feeding-grounds, until I had six apiaries, numbering in all about 1400 stands. The yearly yield from this number was 84,000 lbs., which was extracted and shipped in barrels to New York and Boston.

The principal flora from which the crop is gathered is the tupelo gum and the orange bloom. This latter flower is a favorite of the bees, and suggested to me my trade-mark, "Orange Bloom," which I had patented about 1880. The "Orange Bloom" has one great advantage over any other honey, it will keep for ever without granulating. This "Orange Bloom" honey took the first premium at the Atlanta Exposition, and I was awarded a medal.

I was born in Marianna, Fla., March 19, 1835. My parents were both born in England. I have been engaged in the honey and orange business for more than 40 years, having been blessed with fine health most of the time.

Mr. Alderman was a good beekeeper the year I was born, or 40 years ago, and all the way down the line of years he has been a good and progressive beekeeper—not in and out, but year after year he has continued in his main line of business, that of producing "Orange Bloom" honey. He has produced trainloads of it, and has thereby gathered up around him considerable of this world's goods—at least enough to make him very comfortable in his old age. He spends the summers up in the mountains of North Carolina, and the winters at

S. S. Alderman, of Wewahitchka, Florida, an up-to-date beekeeper for forty years.

his Florida home, which is a beautiful one located on an island on the Chipalo River. His home is surrounded by a beautiful orange-grove on the east and south side, and along by the front flows the beautiful river. A more beautiful or more modern home can not be found in our Southland.

A glance at the face of this veteran beekeeper will show that he has been wonderfully blessed with health. It is strange that he has not been a great writer on bee culture, for he is very intelligent. A better type of beekeeper can not be found in all beedom.

Cordele, Ga.

WHY ORDERS FOR QUEENS CAN NOT ALWAYS BE FILLED AT ONCE

BY PENN G. SNYDER

With reference to Mr. Lewis P. Tanton's article, page 581, Sept. 15, I have made it one of my business principles to reply as soon as an order is received. I use a printed post card that requires only the name of the purchaser and date the order

The effect of poorly attached starters. Notice the combs in the two middle sections have fallen, leaving a space for the bees to fill in to suit themselves.—Sires & Sires, Wapato, Wash.

will be filled. To say the least, however, it is difficult to guarantee to have queens on a given date.

There are several distinct reasons why the expected queens may not make their appearance as expected. "There's many a slip 'twixt cup and lip" is a very true statement when speaking of bees. Our bee pets(?), as we all know, sometimes disregard all rules, regulations, and standards, and apparently set out to see how mean they can act.

One of the many things that sometimes happen is that, after the cells are started beautifully, a couple of days later they may be cut down. They may be chilled or possibly jarred in handling. An unexpected queen-cell in the brood-frames might hatch and destroy them, or a small virgin from an unknown source might get through the protecting zinc which I use to cover all entrances of cell-building colonies.

Then there seems to be nothing easier for the queenless bees in nuclei than to destroy the cells or virgins given them, or for the virgins to disappear while on their mating-trips.

The queen-rearing business is not all "beer an' skettles," as one can readily find out by making an experiment when conditions are not favorable—when there has been no honey gathered for a month or so. Under the best of conditions it is easy to obtain plenty of good queens; but when conditions are the reverse, then comes the need of skill, patience, and knowledge. Then the weather plays a very important part in determining the success of all efforts, to say nothing of the honey-flow.

Yet all this can not excuse the queen-breeder in not replying *at once* to all orders as all up-to-date business men do. He can at least promise, and then do the best he can to fill the order on the date promised.

Personally I can heartily agree with Mr. Tanton in his arraignment of the greater

number of the producers of bees and queens. It is more than annoying to send an order, and receive no reply, possibly, for weeks—an experience I have had repeatedly in years past. "None but the brave deserve the fair." We bee-men can change the above quotation to "None but the prompt deserve our orders," provided they are filled with good stock in good condition.

PURE GOLDEN BEES ARE NOT CROSS.

I have a growing complaint to register. The editor invariably, in speaking of "Goldens," states that they are often very cross, also that they winter poorly. Now, that may be true of some of the strains composed of more or less Cyprian blood; yet in the manner in which the term is used it gives Goldens as a whole, irrespective of strain, a black eye.

I have in my home yard about 80 colonies of Goldens, to say nothing of nuclei, and I do not use a veil on an average of one hour out of ten while working in this yard. I can give names of many beekeepers who have been in this yard, who have seen me, without smoke and without preparation, and, last of all, without stings, open colonies containing eighteen or more combs of brood. Just after a rain, or during one, I have frequently opened the hive containing the breeding queen, and have received *no stings*.

Two years ago I sold to a gentleman in Porto Rico a two-frame nucleus with a tested queen. When the hive was full of bees, and they were working on the supers, his two young sons were discovered grabbing out the honey by the handfuls from the extracting-combs. The children were more or less covered with bees, yet neither of them received as much as one sting. Are such bees cross?

Swarthmore Apiaries, Pa.

[Undoubtedly there are many colonies of Goldens that are gentle and also hardy;

but in our long experience of years we have found that the *majority* of Goldenes are below "par" on these two points.—ED.]

THE COMBINED SUMMER AND WINTER SHED A NUISANCE

BY G. C. GREINER

The general tone of Mr. List's article with its illustrations, page 766, Dec. 1, suggests beekeeping after the old-fashioned let-alone plan. For that kind of management, his combination summer and winter sheds, or stands, as Mr. L. calls them, offer some advantages, although I should prefer a finer material, such as oats, wheat, or clover chaff for packing instead of straw. But for the beekeeper who aims to get from his bees "all there is in 'em" by practicing up-to-date methods, such a thing as "summer and winter stand combined" does not exist unless we apply that term to the properly constructed chaff hives as they are listed by our regular bee-supply establishments. And even these are not as readily accessible and easily managed as a single-walled hive.

The only way that will allow the easy, convenient, and time-saving manipulations of a season's campaign, is to have hives spread over the ground, on separate stands, with about two feet space between. Does Mr. List imagine the time and work it takes to remove the sheds and spread the hives in the spring, and then move them together again in the fall for winter packing is lost labor? If he will follow up the season's innumerable manipulations that are unavoidable with modern beekeeping, such as examining in the spring, feeding, equalizing and spreading brood where necessary, artificial increase, and "shook" swarming, dequeening and requeening, adjusting and readjusting of supers, then a little later the extracting work, and, still later, removing the last supers, feeding for winter, and uniting where necessary, and many others that may unexpectedly loom up in the routine of the season, he will see at once that the time saved by having hives conveniently placed will do that little extra work he considers "unnecessary" a dozen times.

To the experienced beekeeper the disadvantages of crowding bees into close quarters, as shown by Mr. L.'s illustrations, are too well known to need any comment. But I would caution beginners and prospective beekeepers never—no, never, if it can be avoided, to plan arrangements of this kind. It is bad enough to fight the ill-tempered individuals of one colony; but when six are

aroused every time one hive is touched, the overdose becomes (to express it mildly) an annoyance. Individually I am practically immune to bee-stings, although I do not enjoy them; but to the great majority of the human family they are an undesirable donation. For the good of all concerned, bees included, all unnecessary aggravation should be avoided.

In the sheltered position behind the raised roof of his stand Mr. L. may not notice the disturbance he causes to all the inmates of the stand whenever he manipulates either one of the six; but I can assure him that the least jar, even the opening of his roof, is felt by every bee in the lot; and under certain conditions it would be sufficient cause to put the whole company on the war-path.

A slight change in the construction of his cases, which would greatly improve their efficiency as a winter protection, and at the same time preserve both cases and hives, may be an acceptable suggestion to Mr. List; or if not to him to some one else. The opening below the hinged front all along the bottom should be closed by letting the front—in fact, all sides and ends—pass down below the floor. This would shut out water, and keep the snow from blowing in. As it is, a heavy drifting rain from the right direction would saturate the whole under part of the cases and their contents full of water, which a sudden freeze would transform into ice. Snow also is liable to drift in around the straw, which straw would, under certain changes of temperature, undergo the same transformation, and surround his hives with an icy inclosure. While these conditions may not be absolutely destructive, they are in no way conducive to the welfare of the bees.

La Salle, N. Y.

CLIMATIC CONDITIONS AND SURROUNDING FACTORS TO BE CONSIDERED

Windbreaks for Winter Protection; Too Much Shelter Allows the Bees to Come Out when the Air is too Cold

BY A. J. HALTER

I note with interest what Mr. Holtermann says on p. 776, Dec. 1, with reference to tight board fences for windbreaks. Probably his location is more adaptable, owing to climatic conditions. I can not argue from his standpoint, and will only relate my own experience, based on conditions in this locality, a distance of 40 miles south of Lake Erie.

When I first began wintering bees with

Double-walled hives containing live bees buried in snow.

windbreaks I bought a lot of binder canvas, nailing it on posts, taking two strips high, thus affording a height of six or seven feet, and placed the hives to the east of the windbreak. This, with a shield of large apple-trees, seemed a good protection except in case of a few end colonies which were a little weak the following spring. The next season a strip to the south side was added, forming an L, and the bees wintered well, for there was scarcely an air current back of this tight windbreak. Only an eastern or southeasterly wind could reach the entrance of the hives (all hives faced in a southerly direction), and I felt that I had some assurance of successful wintering so far as windbreaks were concerned.

The next fall windbreaks were again put in proper position as last stated, every thing progressing favorably, there being plenty of snow, and the bees were in fine order. About the same time I built a ten-foot tight board fence on the north side of an outyard—there being buildings to the east, and woods and elderberry bushes to the west of the apiary.

The bees did not have a flight for some time; and during the latter part of February there was about a foot of snow. The temperature suddenly rose to about 50 degrees by this time, with a bright sunshine mingled with a light breeze which was melting the snow very rapidly. That evening a neighbor who had passed the yard a short time before informed me of what had happened. The next morning I went to investigate; and, to my astonishment, I found thousands upon thousands of bees scattered all over the snow outside of the windbreak

for a radius of 300 or 400 feet in a westerly and southwesterly direction, and one could scarcely step without treading on bees. The ground was still covered with plenty of snow, even around the hives, where great numbers had also fallen in the melting snow and were lost. There were over a hundred colonies in this yard; and when spring came, several colonies were dead. The rest were very weak. There were, perhaps, ten colonies all told that built up strong enough to store

surplus at the beginning of the honey-flow.

After having viewed the situation I proceeded to visit the outyard which was protected by a tight board fence on the north side only, and arrived there about noon. The snow had a very thick crust, caused by a heavy freeze directly after the thaw. What a relief to find only a few bees imbedded in this crust of snow! I began to study the situation, for the bees had not come out for a flight at the outyard except from several scattering colonies from which a few had emerged. This is how I summed up the situation: At the yard where the windbreak was on the west and north, the sun heated up the hives and immediate surroundings, as the air currents were almost entirely shut off by the windbreaks at the stated time, and it became warm enough for bees to fly out in great numbers. But when they came in contact with air currents they became chilled, and dropped on the snow outside of the windbreak, never to return. At the other yard, the air or breeze came in among the hives and did not warm up enough for the bees to venture out.

Since that I have not put up canvas, but just pile up hive stands or boxes about five feet high where light air currents pass through, and have not had any loss by bees flying out. They seem to winter as well as those at the outyard where the ten-foot fence is still retained and where the hives are placed in five or six rows, about twenty in a row facing south.

Last winter the mortality was mostly in hives in the center rows, being about 35 feet south of the high board fence. What explanation can be given? Possibly the

severe north and northwest winds coming in contact with fences and buildings on the east was forced back and scooped down to the surface of the ground only to rise again in accordance with laws of distribution. This was probably only an incident in accordance with directions and velocity of storm; but would it be wise to reconstruct the situation thus, providing a repetition might come from some other direction? This idea of windbreaks seems about as perplexing to me as the swarming question. When all looks well, something is sure to be wrong. If we knew of coming weather conditions it could be solved accordingly; but as most of our storms or cold winds come from the west or northwest, we naturally make provision accordingly; but when an eastern storm comes we simply say, "It won't last long."

My idea of a windbreak is a location where severe and cold winds are elevated to pass over a certain obstacle, which is more natural where hills or valleys are natural landscapes. An apiary located on a side hill with this natural protection would be the ideal; but, unfortunately, only a small number of beekeepers are so located, and these must adopt the artificial to the best of their judgment and surroundings. A light breeze in an apiary located back of a windbreak is, I believe, essential, as it will bring pure air and destroy dampness, and is less apt to lure bees from the hives until conditions are safe for a general flight. My observations along this line lead me to believe that careful study of climatic conditions and surroundings are the main factors in constructing windbreaks, and that success can be obtained only under favorable conditions.

Akron, O., Dec. 10.

[See editorial.—Ed.]

BEES BURIED UNDER A FOOT OF SNOW AND ICE

BY F. J. LILLIE

The photograph shows how I dug my hives out of the snow March 1, after they had been buried under a foot of snow, having a heavy coat of ice for four weeks. I thought the bees would be all dead; but I lost only one colony out of ten. All seemed well supplied with stores.

Corry, Pa., April 1.

EXPERIENCES OF A FOUL-BROOD INSPECTOR

Superstition and Ignorance

BY J. E. CRANE

Continued from page 21, January 1.

The ignorance of the great mass of beekeepers is past comprehension. So far as I can judge not more than one in six in some sections ever reads a bee journal of any kind. Most of them know little and seem to care less. One family on whom I called told me that the reason their bees had done so poorly was because they had sold bees and had taken money for them. No argument on my part could convince them to the contrary. It was of no use to tell them that the season had been unfavorable. No; they had sold bees and had taken money for them, and they must suffer.

Many seem to think that, if they succeed in hiving a swarm, and then place it on a stand in the back yard among the bushes, or over by the hog-pen, or leave it sitting on the ground, their work is done.

Somewhere I tipped up a hive from the bottom-board, and began scraping off what appeared to be a scab from the bottom of the combs so as to get into them to examine them, when the proprietor informed me that I was tearing off what remained of the old bottom-board that had stood or rested on the ground until it was rotten, after which the hive, rotten bottom-board and all, was set on a new board and given a stand.

One man declared to me that the apple worms (tent caterpillars) got into his hives and spoiled combs, "Do you know they were tent caterpillars?" I asked. He said he did, for he could see the cocoons they had left! A friend of mine, an inspector in another State, tells about finding a hive standing on the ground, and weeds growing up through it; also of another where the combs had been cut out and old burlap stuffed in to fill the empty space.

An experienced beekeeper was telling me how one of his neighbors came to him in trouble. His bees had been getting something that made them drunk. He went over to see what was the matter, and found that the hives were standing about two feet above the ground while the day was cool, and all of the bees that missed the entrance fell to the ground, and, being chilled, were unable to rise again, so they crawled aimlessly around to be reported by an ignorant beekeeper as drunk. What a shame! I have said to myself many times, "If bees will live under such conditions, what would they do

with intelligent care?" No domestic animal would live with such treatment as bees receive. It is a great pleasure, after visiting such beekeepers, to meet intelligent apiarists who are readers of bee journals. They know who the inspector is, what he has called for, and are ready to give him any assistance in their power. They don't need an inspector, for they have been doing their own inspection, and can tell to a dot just the condition of their bees, and whether they have any contagious disease or not.

I called on one of this class; and after I had looked into a good many hives he said, "The colonies in that row of hives have Doolittle queens; in that row, Moore queens; and in that row Hand queens," and I envied him the fun of watching the differences in these three strains of Italian bees, for he had enough to give him a pretty good idea of their relative value. The inspector would like to stop to visit a long time with such; but "beesness is beesness," and he must move on.

SOME OBSERVATIONS ON EUROPEAN FOUL BROOD.

European foul brood in an apiary is always an interesting study. If the disease has not made great headway, I have found from one to three colonies very bad, and between a dozen and twenty in the earlier stages of the disease. There seems to be some relation between the very bad and those in which the disease has only begun its deadly work.

I visited a yard the latter part of the summer where I found the disease well advanced and in all stages. In this yard the whole process of ruin could be observed. The first colonies that came down had reached the last stage, and were a mass of worms, filth, and cocoons. Only one out of twenty-four colonies was still healthy, while the rest were in all stages of foul brood.

When the first colonies that come down become weakened, robbing sets in and disease is carried to the other hives. As soon as the bees become too weak to protect themselves against moths the one happy home is soon changed into a mass of ruins, and the beekeeper vainly believes that the moths are at the bottom of his trouble, while they are only the scavengers that have consumed what was left by disease and the robber bees.

QUESTIONS ASKED.

The questions that are asked an inspector are often amusing. For instance, "How long does it take to learn beekeeping?" To this I reply, "I have been at work learning for more than forty years, and

haven't it all learned yet." Or a more frequent question is, "Do bees ever sting you?" "Yes," I tell them, "I suppose I have been stung more than seven or eight times in the past forty years," and likely I may hear their exclamations of surprise that I should continue the business and take such risks.

THE RIGHT WAY TO MANAGE.

It is a great relief to me when I get such a letter as I received last summer from a woman in a neighboring town. She said she was afraid that they had foul brood among their bees, so she had sent a sample to Washington. Later she wrote me that it proved to be genuine European foul brood. I was not surprised, a little later, when I called, to find GLEANINGS on the table. Now, how sensible! She had inspected her bees and had observed something wrong, and had done just the right thing in sending a sample of the brood to the Department of Agriculture at Washington instead of waiting until her own yard was ruined and her neighbors' yards exposed. If all who keep bees were as prompt, the disease would soon be stamped out.

WASTEFUL NEGLIGENCE.

In opening hives I have been surprised at the great amount of drone comb I find near the center where brood-rearing begins in early spring, and where worker comb is to the last degree necessary.

I often find combs lying around on the ground and going to waste that might be saved and made into wax. I have often thought it would be money well spent to send an inspector around among beekeepers to instruct them, even if there were no such thing as disease. I wonder if they would take the lessons to heart, and practice what they were taught.

Middlebury, Vt.

To be continued.

THE TREATMENT OF EMPLOYEES ON A BEE-RANCH

BY SUBSCRIBER

My own experience in California was something after the same style as the experience given on page 350, June 1, so it may interest some of your readers.

The majority of ranchers in this State, including the beekeepers, appear oblivious of the fact that their hired help are of the same flesh and blood as themselves, and that, possibly, may account for the treatment meted out to them by their employers.

I answered an advertisement for help on a bee-ranch, not because I knew any thing about bees, but simply that I was out of employment and needed the money. I was

to receive \$30.00 a month, and room and board. The room was the veranda. I was supplied with a spring cot and blankets.

As to board, breakfast consisted of badly cooked greasy bacon, dry bread with a tough crust, flapjacks cooked in an old frying-pan which was as black as charcoal, inside and out (honey supplied the place of butter and sugar), canned milk liberally watered, and prunes. The latter were put on the table in the same pan in which they had been cooked. Dinner consisted of fried bacon, boiled beans, and a kind of stew composed of macaroni, tomatoes, potatoes, and bacon grease. Bacon and leftovers from dinner were used for supper. I saw fresh meat about half a dozen times in three months, and then it was usually liver. When the crew worked the apiaries away from home, the lunch consisted of canned beans, a cheap grade of sardines, and dry bread.

The cook employed by this outfit was an old man past 80, who had been a miner in the early days. What salary he received I never discovered. I only knew that he never by any chance cleaned out his kitchen, the floor of which bore the grease of ages.

As you may readily imagine, a few days of this kind of thing was usually sufficient for most of the help who came. As an inducement to some of the help to stay, they were offered a bonus of \$5.00 per month if they stayed during the entire season. But this failed to hold most of them.

A young fellow from Chicago, after putting in about four months, was carrying a hive of bees, when he stumbled. The owner happened to see him, and shouted, "If you had dropped that hive I would have knocked your d—d head off." I asked the young man why he stood for that kind of thing, and he replied, "Oh! he wants me to quit so he won't have to give me the extra \$5.00." Is this the kind of treatment to be expected on bee-ranches?

About this time of the year a good many men from the East come to California in answer to advertisements for help. Let me give them some advice. First, if you can get any kind of labor by which you can get enough to live on, stay where you are. I honestly believe from personal observation that there are more able-bodied men working for their board and a small pittance, in the State of California, than in any three other States in the Union.

Second, hired help in most ranches is required for only a few weeks, after which the men must hunt other work. They must carry their own bedding. The board is inferior, and so are the sleeping accommodations.

There is an old story told of a hired man who, on asking the employer where he was to sleep, received the reply, "I own 5000 acres around here, and you can sleep anywhere you like outside the house."

[We are afraid our correspondent is a little hard on the California men as a whole. We have known students who have been treated most royally by their employers in the Golden State.—Ed.]

BEEKEEPING IN THE SOUTHWEST

The Scholl Improved Hive-numbers

BY LOUIS SCHOLL

Continued from page 43.

course, the number can be painted with a brush, but it can not be done as nicely nor as quickly as with the rubber stamps.

They are easily applied to either end of any story at any part of the hive by simply hanging over the edge of the upper story or the rabbit of the hive. Fitting snugly, they do not interfere with the ends of the frames nor with any upper stories or supers piled on, nor with the covers, as those slip right over them. These numbers can be changed quickly to any other part of the same hive or to any other hive.

They are always securely in place, being either locked down by the covers of the hives or the upper stories and supers. Hence they can not be misplaced easily by a strong wind, and are more secure against mischievous depredators who might be apt to remove them or exchange them on the hives, and thus cause considerable trouble.

They are cheap and everlasting, therefore, and I am giving them to beekeepers who desire a good hive-number as the "Scholl improved number-tags." You are welcome to use them if you like them.

New Braunfels, Texas.

CONVERSATIONS WITH DOOLITTLE AT BORODINO, NEW YORK

Continued from page 44.

In addition to what I have already given you, use partly finished sections, which are generally quite numerous during the middle of July; and if you thin the honey to about the consistency of the nectar as it comes in from the field when it is given to the bees you may be quite certain of a profitable outcome. Lacking in any of the points given, any one trying the experiment is likely to conclude that his time and honey can be more profitably used otherwise.

WHY DO BEES DISLIKE BLACK?

Some Interesting Data; Black Objects Stung by Bees because More Visible

BY JOHN H. LOVELL

In GLEANINGS for December 1, 1912, Mr. J. E. Crane says that it is the almost universal opinion that bees dislike black. So far as my experience goes (and I have given considerable attention to the matter during the past few years), this would appear to be undoubtedly the opinion of the majority of American beekeepers. Now, why should bees dislike black? They will gather honey indefinitely from a piece of black paper or from a black dish. A part of my winter cases are painted black; but I have never been able to discover that the bees exhibited any antipathy to them on that account.

On the other hand, let an animal wholly or partially black approach the hives, and the evidence is most convincing that it will receive more stings than if it were entirely white. Of a flock of twelve black chickens running in the bee-yard, seven black ones were stung to death while the five light ones escaped (GLEANINGS, March 1, 1911, J. Ridley). A dog with a black rump is badly stung on this part, while the white portion of his body is comparatively free from attack (GLEANINGS, March 1, 1911, H. C. Driver). As mentioned by Mr. Crane, a white horse may be driven near the apiary with less danger of its being stung than a black one. Another correspondent has told how a white dog ran among the hives without attracting much attention, while at the same time a black dog was furiously assailed by the bees.

Many beekeepers report a similar experience from wearing black clothing. A white coat does not excite the bees so much as a black one (GLEANINGS, March 1, 1912). Dr. Miller gets more stings when he wears a dark suit than when he wears a light one (GLEANINGS, Dec. 1, 1906). Mr. Huber H. Root had a black felt hat "literally decorated with stings." On changing to a gray hat he did not get a single sting. The black head of a hat-pin is repeatedly attacked by bees. A pair of black stockings substituted for bee-gloves is literally "peppered." The editor of GLEANINGS has related that, while examining one of the apiaries of Mr. E. D. Townsend, he wore a dark suit and received more stings than Mr. Townsend, who was dressed in a white one. Elsewhere he has expressed the wish to have the question discussed further.

All beekeepers, however, do not agree

that it is the black color which excites the anger of the bees. One observer suggests that it is a question of education. Editor Root received more stings than Mr. Townsend because he was a stranger. The bees would have treated him more kindly if he had given them a little time to get "educated." However this may be in the case of beekeepers, it does not help us any with the black and white dogs, or the black and white chickens. Here both were equally strangers. Another beekeeper thinks that it is not so much the darkness as the roughness or hairiness which annoys the bees. To this Dr. Miller replies that he has seen at least a dozen bees viciously jabbing at the smooth glass head of a black hat-pin, following it for half a day.

The *Irish Bee Journal*, according to Dr. Miller, hinted that had he put on a clean shirt he would have had fewer stings; that is, it was the odor and not the color which offended the bees. As would be expected, the doctor replied that the shirt was newly put on, and was void of offense in the particular mentioned. Dr. Miller's photograph, indeed, effectually refutes such an imputation. The above-mentioned editor seems rather to scout the accepted opinion, and says that he has worn a black felt hat and didn't get any stings. St. Patrick, so it is authoritatively reported, formerly drove all the snakes in Ireland into the sea. Possibly the good saint, while he was about it, blunted the stings of their bees a little. However it may be in green Erin, bees in America certainly sting black objects, if endowed with life, more freely than they do white.

Let us consider for a few moments the psychology of colors in an endeavor to ascertain if one color ever irritates more than another. A bright-red garment, as many know from experience, will greatly enrage the turkey-gobbler or a bull. Boys sometimes use pieces of red cloth as a lure to catch frogs. Physicians state that children wearing bright-red clothing and people living in bright red-rooms are often very nervous and irritable. These symptoms disappear when another color is substituted. There are persons who can not bear to look at red. The case of an officer is cited who was made giddy by red.

There is a word for red in every language, but not always one for blue. Savages use red pigments in painting their bodies more than any other hue. Red is claimed to exert more motor power on the eye than blue. Soldiers are no longer dressed in scarlet. Persons suffering from melancholia are benefited by looking at red; but insane patients may be rendered uncontrollable. A

man will become intoxicated more quickly in a room painted red than in one which is blue.

Smallpox patients escape pitting if they are placed in rooms with red glass. Under the advocacy of Dr. Finsen, red-light treatment has been widely extended. There can not be any doubt that red waves of light tend to excite the nervous system. The ether waves which give rise to the sensation of red are longer than those of any other color. Accordingly we should expect that the color with the shortest waves, as violet, would produce the opposite effect, or be very depressing. This is the fact; and those who live in dark-blue or violet-colored rooms are apt to be low-spirited. It is said that state prisoners in Russia are sometimes confined in rooms with the walls painted a deep violet, with the result that the mind in time becomes enfeebled and helpless. Red in moderation is a warm stimulating color; but in excess it becomes an irritant.

If black were a color we should conclude that the waves of light from it irritated the bees. But black is not a color. An object is black because all the rays of light are absorbed; it is white because they are all reflected. Now, we do not see how black can irritate the bees when it does not, like red, give off any rays of light to affect them. The physical cause, waves of ether, is absent. So far, then, as finding out why bees sting a black animal more than they do a white one, we do not seem to be much better off than when we started; but we have narrowed the problem.

Are, then, bees angered by black?

We think not.

Is there no other explanation of their apparent dislike for black?

Some time ago, if I mistake not, it was suggested in GLEANINGS that perhaps the true explanation is that bees see a black object more quickly than they do a white one. This, in my opinion, is correct. Undoubtedly in the glaring white light of a day in midsummer a black object is more rapidly seen than one which is white.

In the polar regions all forms of animal life, whether mammals or birds, in the winter season become white like the snow. In contrast with the vast expanse of white landscape a black object would be very conspicuous. A black coat is equivalent to a death sentence. A bee hastening out from the darkness of the hive would more readily see a black object than one which, like white, is less visible in the intense light. Like white, a mirror reflects the larger part of the rays of light; and if one could be constructed which would reflect them all it

would be invisible. Failure to detect the presence of a mirror has, indeed, been the cause of many mistakes.

Again, a black surface in bright sunshine is several degrees warmer than a white surface. This additional heat may also exert some influence in attracting the attention of the bees, though this is doubtful. As bees pass so large a portion of their time in the darkness of the hive, it would certainly seem improbable that blackness *per se* would annoy them.

The disposition of the bees and the way in which they are handled are likewise factors which must be considered. Nor in emphasizing the supposed dislike of bees to black must it be forgotten that they very readily sting white objects. The case was mentioned of a beekeeper who used a pair of black stockings instead of gloves, with the result that they were stung very badly. I always wear white gloves, but at times the bees attack them very fiercely and in great numbers. On the whole, then, the supposition that bees see a black object more readily than they do a white one seems to afford a satisfactory explanation of why at times they sting the former more freely than they do the latter.

It follows that one of the principles of apiculture is: Let every beekeeper dress in white.

Waldoboro, Maine.

CARNIOLANS AHEAD OF ITALIANS IN MANY RESPECTS

Their Tendency to Swarm Excessively Overcome Easily

BY E. F. ATWATER

In this locality we have never had black bees unless rarely from a mismated queen sent here by some breeder in the East or South. With this condition, and for many years with nothing but Italian bees, we are prepared to say that the idea so often advanced that Italians will, when left to themselves, degenerate to blacks, or approximate that type, is a myth, pure and simple. The existence of this long-time myth, false as it is, has been dependent on the fact that in most localities the bees, of more or less black blood, in woods or rocks or box-hive apiary, will rear a vast number of drones compared to the few that are usually allowed in an up-to-date apiary.

Excellent as are the Italian bees, they are not superior in all respects for all localities. For several years we have been slowly and rather cautiously adding a little Carniolan stock. We know that the Carniolans (not necessarily pure Carniolans), rightly man-

aged, will average to bring a larger force to any flow than any strain of Italians.

Unlike Mr. Holtermann, p. 10, Jan. 1, 1912, we have had excellent success with these bees when using the eight-frame hive; but we add one or two stories to accommodate them before the flow, or else we draw from the Carniolans to build up the Italians. However, we are working more toward a large hive, using ten-frame size largely, and have no doubt that in many ways the twelve-frame may be better.

BANATS A FAILURE FOR COMB-HONEY PRODUCTION.

Three years ago the enthusiasm of a near-by beekeeper for the Banats led the writer to try 130 queens of this stock, as they were very highly recommended by several. They were one of the finest and most uniform lots that I have ever seen, and they arrived in splendid condition after their long journey. They were nearly all successfully introduced. This was one of the most disastrous mistakes in my experience. The much-praised non-swarmer comb-honey Banats will build up to great strength in the spring (much like the Carniolans), swarm as much as any bees, and when a good flow comes they crowd the brood-nests (if comb honey is produced) so that they are scarcely numerous enough to work one super when the second flow arrives. They winter well, but their product will run at least one super per colony less than any bees that I have ever owned. Only one Banat colony of all that I have owned has made 100 sections of comb honey, while many Italians, in the same season, far exceed this amount. This inferiority is not so apparent if extracted honey is the product; but naturally the Banats are being weeded out of our apiaries, while the Carniolans are being used in increasing numbers.

We usually buy and breed some of the best Italians every year, having, one season, 30 Italians from a famous breeder that gave us at least one dollar per colony more than the average from the remainder of the yard.

Since but few breeders can supply purely mated Carniolan queens, we sometimes buy many of them mated to Italian drones, as that strain is better than a lot of uncertain black and hybrid bees. Then we have an imported breeder to use when we have time to rear some of our own queens.

We have occasionally had a few Carniolan colonies that would fill two supers before any Italian colony would fill one, and their white cappings and hardness are valued while their prolificness is a decided help in handling disease. If it is true that

the Italians are so superior to the Carniolans in handling disease, how is it that the late Capt. J. E. Hetherington, with his thousands of colonies, was, before his death, introducing hundreds of Carniolan queens into both the Virginia and New York apiaries, in the latter yards finding them a great aid in combating disease?

If they are such great swarmers, how is it that Capt. Hetherington could handle them to advantage in his many yards?

If, as claimed for them, they are likely to convert their surplus into brood, how is it that our helpers find our Taylor yard, mostly Italian blood, very light for winter, while in the Highland yard, three miles south, with Carniolan stock, the hives are packed with stores?

If they are such great swarmers, how is it that a row of 20 of them in the home yard, with but little care, made over 100 lbs. per colony, and cast only two swarms, while the entire yard averaged but 63 lbs., there being but little Carniolan blood in the other colonies?

The beekeeper who can not adapt his manipulations to the racial characteristics of the Carniolans had better continue with the Italians. But for those who will so adapt their methods, the Carniolan race offers some marked advantages in some localities.

Meridian, Ida.

Preventing Granulation in Comb Honey

In looking over a copy of GLEANINGS for May 15, 1909, page 305, I notice an article on candied comb honey, by Frank Rauchfuss. In the footnote to the article you speak of experiments you were at that time conducting in trying to liquefy candied comb honey without spoiling the sections in any way. You say the chief difficulty is in keeping a steady temperature. This subject has interested me for some time past. If you will give me any information in regard to the experiment I shall be greatly obliged.

Forest Park, Ill., Dec. 16. J. W. ALLERS.

[We finally abandoned all attempts to keep comb honey liquid by very high heat. We do, however, store our comb honey in a room, the temperature of which rarely goes below eighty degrees Fahrenheit, and we aim not to let it go above ninety. A rapidly changing temperature from cold to hot, and *vice versa*, is conducive to granulation. We have actually reduced granulation by keeping the honey around 103 degrees Fahrenheit; but the expense of the undertaking is far greater than the advantages warrant. Besides this, there is very great danger of the honey melting down suddenly so that large quantities are lost outright. Some combs will stand a higher temperature without sagging down than others, and some honey requires a higher temperature to be reduced, so that, take it all in all, we have come to the conclusion that the best way is to sell comb honey *before* it granulates, and not be obliged to resort to expensive experiments after granulation has actually begun.

By a little effort granulated comb honey can be sold. There is nothing wrong with it so far as taste is concerned, although if sold indiscriminately to those who do not know what it is, it is likely to cause suspicion of adulteration, the average person thinking that it has "gone back to sugar."—ED.]

Heads of Grain from Different Fields

Making Increase and Honey at the Same Time; Feeding Candied Honey as a Winter Food; Carniolans Excessive Swarmers

I have 20 stands of bees (Italians), and want to build up to at least 100 the coming season, at the same time getting what honey I can. I have planned to set aside a few hives to work for increase, dividing as soon as I safely can in the spring, and by so doing leave half or more of my bees to harvest undisturbed what honey they can.

From the time the first willows start in April until the last of the sweet clover and goldenrod is killed by the frost in October we have no time when pollen and nectar can not be found if the bees can fly.

I have some 175 lbs. of thick honey, candied, that I am holding for stimulative feeding, but have had no experience; in fact, the past is my first season's work with bees. I was fairly successful in building up by separating into two-frame nuclei, and either providing a queen-cell or eggs and larvae. I am using Danzenbaker ten-frame hives, but shall change to the double-walled of the same dimensions.

Can you give me any hints that will steer me clear of the pitfalls I am apt, as an amateur, to fall into?

Are you still of the same opinion regarding the Carniolans, as when the 1908 edition of the A B C book was published?

I don't enjoy the "glue" left on the frames in the fall, nor do I want to fight swarming all of the time. The last is all that keeps me from trying the Carniolans, and doing away with the Italians.

Ironside, Ore., Dec. 15. A. W. ANTHONY.

[Your plan of dividing your colonies by running one portion for honey and the other for increase is correct. It is usually a mistake to try to secure increase and honey both from the same set of colonies, although there are some seasons when a heavy flow of honey will enable the apiarist to secure both increase and honey.]

For the best methods of increase we would refer you to the subject of "Increase" in our A B C and X Y Z of Bee Culture. The Alexander plan has much to commend it.

Your locality is exceptionally favorable, for it is seldom indeed that bees will be able to secure something, either pollen or honey, whenever they can fly.

Your candied honey can be given to the bees direct, providing it is not dry and hard. In fact, feed in that form is an excellent thing to give to bees either in the North or South. In your climate there is danger that your candied honey will "run" and daub the bees. We would advise putting it in wooden butter-dishes or on paper pie-plates, so that in case it becomes mushy the receptacle will hold it until the bees can take care of it.

In a general way we are not able to give you hints as to how to avoid pitfalls; but if you are a beginner we would suggest that you read "Spring Management," "Robbing," and "Feeding," in our A B C and X Y Z of Bee Culture.

Our opinion concerning Carniolans has not changed since the 1908 edition of our A B C and X Y Z of Bee Culture was put out; and while the edition of 1913 contains new matter and fuller details as to their undesirable as well as their desirable traits in the line first mentioned, we can not make the emphasis too strong that Carniolans are the most inveterate swarmers of any strains of bees we have ever tried. Last year our sixty or seventy colonies of Carniolans at our waterworks yard gave us more trouble in the matter of swarming, twice over, than our five other yards of Italians combined. Ordinary methods of swarm control will not work with Carniolans. For the production of comb honey they would be very undesirable, for the simple reason that the ordinary methods of comb-honey production would

cause them to swarm excessively; but in the hands of some experts Carniolans are excellent for the production of *extracted* honey. We would, however, advise the average beekeeper to try a few of them in a yard by themselves before he invests in them largely. We should much prefer the leather-colored Italians for all purposes, to either Carniolans or Caucasians. The latter are about as bad for swarming as the Carniolans. In these days of out-apiaries it is desirable to have a strain of bees that will swarm as little as possible. The ordinary leather-colored Italians will give as little trouble in this respect as any.

The bee-glue deposited by the Italians is nothing compared with the amount deposited by the Caucasians. The Carniolans are only a little better than good Italians in the amount of bee-glue they use.—Ed.]

Ideas for Up-to-date Honey-house Wanted

I started five years ago with a few stands of bees as a side line to ranching, and they have increased until now they take up practically all my time during the summer.

The expansion of the business makes it necessary to build a new honey-house in which I desire to put all up-to-date equipment for both comb and extracted honey.

I should like to have, through the medium of GLEANINGS, plans for building, location of doors and windows, and placing of equipment for convenience of work and economy of floor space. I can obtain water power from a nearby irrigation ditch to run saw, extractor, and other machinery, and should be pleased to hear from experienced persons as to some manner of installing.

Cedaredge, Colo. GALE H. PATTERSON.

[There have been other inquiries of a similar nature. We should be glad to hear from those who have had experience.—Ed.]

Outdoor Feeding for Supplying Winter Stores

This fall I began looking over my colonies early in October, and found a number of colonies that had not over a pound in the hive.

I took a burlap sack that was woven tight, and made it about the size of a stove-pipe, and about 30 inches long. Then I made some half-and-half syrup, and when it got cool I poured it into this sack and hung it out in a tree about ten rods from the apiary. Then I put a dish under to catch the drip. In this way the weak ones could get their share.

Swartz Creek, Mich. CHARLES BURTON.

[While the bees of weak colonies get some of the syrup when outdoor feeding is practiced, they do not get as much in proportion. For this reason the safest plan is to feed each colony individually, to an extent depending upon the needs of each.—Ed.]

How Many Hives Needed to Provide for Increase?

Last year I started an apiary in June with 15 three-frame nuclei of pure Italians. The bees built up strong by fall without help, and made about 300 pounds of surplus honey. I wintered them in an ideal bee-cellar, under my residence, with no loss. They came out strong last spring. They increased to 36 good strong colonies, and produced for me 2000 lbs. of surplus comb honey in one-pound sections. Last year was a very poor one for honey in this locality, but the season was very good this year.

I put my bees out on summer stands last spring on April 8. I put them in last fall, Dec. 19. This fall I put them in Dec. 8. My hives will weigh from 70 to 90 pounds now. They are all ten-frame dovetailed hives.

From the time I set the bees out last spring until about Nov. 1 we had almost a steady flow of some kind. I was not troubled at all by robbers. I had four swarms about Sept. 1. All made good. How many hives should I purchase next year normally? Lewistown, Ill., Dec. 12. CALVIN BROWN.

[The number of new hives you will need depends largely on your management. If you intend to do all you can to keep down increase you would not need many new hives—perhaps ten would be sufficient. But if you permit natural swarming, or if you follow artificial methods of making increase, you may need as many as thirty or forty.—Ed.]

Mixing of Bees in a House Apiary

Dr. C. C. Miller:—I have built for little chickens a brooder-house 100 ft. long and 16 ft. wide. I wish to use the floor for the little chicks, and a shelf 18 inches above the floor to set the hives on, facing the outside, with an alighting-board running the full length of the building. Some distance above the hives is a door 18 inches wide and the length of the building, to raise up in summer time. Do you think the bees would have any trouble in finding their proper entrances, or would give any trouble inside the building?

I thought this a good plan for protection of hives in all weather, and chicks on floor space below.

I have noticed that some say the building must be painted different colors on the outside.

Lafayette, Ind., Dec. 15. WM. H. ROBINSON.

[As the entrances are well lighted there should be no trouble about the bees finding them. Yet with entrances so close together, and all alike, there will be some mixing. Different colors painted over entrances will do some good, but I suspect that bees pay even more attention to form than to color. Some advise different form as well as different color over entrances, as a circle over one, over others a triangle, square, etc. Still better, have trees, or even posts, to help locate entrances. One or more trees within five feet of the building will help much, even if the trees are small. Instead of having the alighting-board continuous, you had better have a separate one for each hive. There should be no chance for bees to get into the building near entrances from outside, unless the building be so freely open that no bees would be imprisoned.—C. C. MILLER.]

Small Introducing-cage did Not Work Well

I have used a queen-cage with the block on one side, described by A. V. Small, page 762, Dec. 1, but it did not work well for me. The queen would stay in the cage for a week after the candy was eaten, rather than crawl out through a hole $\frac{3}{8}$ inch in diameter and one inch long.

I find that it works better to press the cage into the comb about $\frac{1}{8}$ inch, and place in it five or six bees just hatched from the colony to which I wish to introduce the queen, together with the queen. I tie a wire around the frame to keep it from pulling off. I place the frame at one side of the hive, and after four or five days remove it without using smoke. If the queen is out I remove the cage, replace the frame, and do not disturb it for ten days or more.

A. L. C.

The Carbolic Acid Solution Should Not be too Weak

On page 761, Dec. 1, E. D. Townsend says, "We use a one-to-one-thousand solution of corrosive sublimate or carbolic acid." The corrosive-sublimate solution is of the proper strength, and will work all right, but must not be made or used in a metal vessel. A solution of carbolic acid of 1 to 1000 is not strong enough to be of any use for killing spores. When used in place of a 1-to-1000 solution of cor-

rosive sublimate, a carbolic-acid solution should not be less than 1 to 20, and should always be made by pouring boiling water into a vessel in which the proper quantity of acid has first been placed.

THE COFFEE A SUGAR.

On page 771, regarding "A" sugars, before the introduction of granulated sugar in this section of the country we had what was called "Standard" or "Straight A" sugar. This has been displaced by granulated sugar. We also had "Coffee A" which was of a light-yellow color, and fits the description given by Mr. Miller of the "Coffee A" of to-day, with which I am not familiar. Before the introduction of granulated sugar, many merchants would substitute what were known as "Off A's" for "Standard A" sugar; the "Off A's," as the name implies, were a little off in color, and moister than the "Standard."

Scranton, Pa., Dec. 9. L. F. HIORNS.

How to Recognize Honey-dew

How can I recognize honey-dew when examining for winter stores?

St. Paul, Minn., Dec. 9.

J. PETERS.

[It is rather difficult for a beginner to recognize honey-dew, especially when there is but little of it in proportion to the amount of honey in the comb. In fact, it is often difficult for one who has had experience to be able to say definitely whether there is honey-dew in the combs. A chemical analysis reveals honey-dew, of course, but this is out of the question ordinarily.

By holding the comb up to the light, one can often detect honey-dew by the muddy dark color. Pure honey which is dark in color, unless it is beginning to granulate, is generally clear, though dark; while honey-dew, if there is very much of it at least, has a dirty smoky color.

The taste is different from that of any kind of honey, as it is rank and disagreeable; and if the contents of the comb are nearly all honey-dew, the flavor is often quite bitter.—Ed.]

Cause of Fermentation of Jamaican Honey Late in Season

In Jamaica, honey ferments in the comb as well as in the extracted form; but this happens only to honey gathered after the month of May. In June and July, fruit commences to ripen in great quantities, especially the mangoes, and it is the juices of the fruit which the bees gather, and with which they adulterate the honey, that cause the fermentation.

BEES GATHER POLLEN WHETHER THEY HAVE A QUEEN OR NOT.

The fact that the bees are carrying in pollen is no proof that the colony has a queen. The above reminds me of a youth of about sixteen summers who visited my apiary, and who professed to know a lot about bees. On seeing a bee enter its hive with a load of pollen, he exclaimed, "Oh! I am sure that colony has a queen." "Why are you so sure?" I asked him. Then he began to explain that, if there was no queen in the hive, there would be no young larvae to feed; hence the bees would not gather pollen. Becoming somewhat interested in the lad I asked him to see whether the colony really had a queen. I now discovered that all the youth knew about bees was the difference between a cross colony and a gentle one. He must have read about pollen in some ancient bee-book.

Four Paths, Clarendon, Jamaica, B. W. I.

Meeting of New Jersey Beekeepers

We were obliged to change the date of the meeting to Dec. 20, but we had a large and successful meeting, fifty being present. There was a fair show of honey, considering it was the first attempt at

a venture of this kind for this Association. There were four entries of extracted honey, three of comb, and two of old beebooks. Harold Horner, of Philadelphia, did the judging.

For the best display of old books, the award was given to Mr. J. H. M. Cook, of Essex Fells, N. J., who had one of Quinby's first edition as well as an old one by Miner, and a *Beekeepers' Journal*.

For the best honey in $4\frac{1}{4} \times 4\frac{1}{4}$ plain sections, W. B. McNamee secured the reward; and for the best in 4×5 plain sections, E. G. Carr was the winner. There were no beeway sections shown.

New Egypt, N. J., Dec. 21. E. G. CARR, Sec.

Trading a Skunk for a Colony of Bees

In December, 1901, I got my first stand of bees. We were cutting wood, and caught a civet cat (small skunk). On the way home we passed the house of a trapper, and he wanted the civet and tried to buy it. As he had no money I asked him how he would trade a colony of bees for it. He asked me a dollar to boot, so I gave it. I tied them on the back of the buggy and took them home.

The rest of the folks all laughed at me; but I had always wanted bees, and was going to see what I could do with them. I had an old A B C of Bee Culture that my grandfather gave me. I bought two Danzenbaker hives. I let the bees swarm once, and then transferred them. I used no veil nor smoker, and didn't get stung; but I soon learned better in trying to give a wild swarm. It was on the corner of a neighbor's house, and was trying to go into a knot-hole where there were some bees. I got my hive fixed on the ladder, and took a weed to brush them off. I got about 25 stings, but I secured the bees.

I have tried about all of the different sizes of hives; and the best for a beginner in this State is the ten-frame dovetailed. No beginner should use any smaller, and I think all manufacturers should have a notice to that effect in their catalog. I have the Danzenbaker; and while it is excellent for the purpose of getting the honey in the super, I always have to feed or put on a super of shallow frames for winter. I always get my biggest colonies and the most honey from the ten-frame hives.

I think one of the most serious mistakes that most beginners make is in not having a good strain of bees. I always get from 30 to 50 lbs. more honey from my pure Italian bees than from the common bees. The best queen that I ever had lived three years, and her colony always ran 100 lbs. ahead of the rest. They swarmed once in that time. I have always found it easy to keep down swarming.

There are few people who will make good in the bee business, as most of them do not understand bees, and will wonder why they don't do better.

I gained some valuable information in helping to move an apiary of 40 or 50 colonies, all kinds of hives, and in all conditions. Most of them had not been opened for years. Part of them had combs and honey on the outside. Some were rotted out. It took four of us the greater part of a day and all night to get them nailed up.

Blaine, Kan., Dec. 11. W. V. PITTENGER.

Mating of Queens

One thing does not seem clear to me in regard to queen-mating and queens clipped to prevent swarming. You say they mate only on the wing. Well, what is a queen worth with one wing off? They come out and flutter around on the ground alone.

In the Jan. 1st issue for 1912 some one wanted to enlighten beginners by asking questions and answering them himself. In his description he makes

out that the worker bee is only a stunted female. I didn't suppose the Creator made any stunts.

Greenleaf, Idaho, Dec. 19. B. H. VANTRESS.

[Queens very rarely meet a drone more than once, and this mating takes place within a week or ten days after the queen has hatched from the cell. If a beekeeper should clip a virgin queen, that queen would, of course, become a drone-layer. The idea is to clip the queen *after* she begins laying worker eggs, and then she will continue to lay fertile eggs, even though she never meets a drone, again, for from two to three, four, and sometimes five years more. There are records of clipped queens that have been profitable for six years.

It is true that the worker bees are undeveloped females, really stunted in their growth by coarser food given in the larval stage and the smaller cells. This is proven by the fact that the workers have every female organ, although in rudimentary form. —Ed.]

Hive-tool Made of Old Sheep-shears

Mr. Crane's trouble with hive-tools, page 763, Dec. 1, makes me think it would be a good thing for the inspector to carry a good hive-tool. I used to use a screw-driver, and thought it was all right; but I should like to give a description of an article that will make a better hive-tool than a screw-driver, and it may be found on almost every farm.

Take an old sheepshears. Cut it into two equal parts; bend the flat part of the handle so it will form a ring. Wrap the handle with sheep-twine; break off the point so it will be about $\frac{3}{4}$ inch wide. One side of the blade is oval. It should be ground flat so it will not spoil the hive. Then you have a fine tool.

Sycamore, Ohio, Jan. 1.

C. A. HALE.

Bee-stings Had no Effect

The enclosed letter from Geo. Shiber will interest the readers of GLEANINGS. I have not changed my mind on this subject. There is but one rheumatism, the inflammatory type, and this is a germ disease. Bee-sting poison has no effect on it.

Buck Grove, Ia.

A. F. BONNEY.

[The following is the letter referred to.—Ed.]

My boy, fifteen years old, is just recovering from a bad attack of inflammatory rheumatism. His joints were swollen badly. The truth is, he has been stung to "beat the band" all summer, and he helped all the time while we were extracting 8000 lbs. of honey. The stings did not stop the rheumatism.

Randolph, N. Y.

GEO. SHIBER.

Another Report Favoring Silverhull Buckwheat

The hot dry spell caused a short clover-honey flow last summer; and since the Japanese buckwheat has been grown here the honey from buckwheat has been very light in color. If we go to a field of silverhull buckwheat in full bloom in the morning, it will be alive with bees; but in a field of the Japanese there will be but a few bees at work. The Japanese yields more grain by far, and that is the reason that it is grown so largely.

Bartonsville, Pa., Dec. 22.

ELWOOD BOND.

Limiting Time for Inspection to a Short Period

It has been proposed in Vermont that the time for foul-brood inspection be limited to a very short season, and the bill will be introduced at this session. As no other State has done this it might be well to have the opinion of some practical beekeepers. The member from this section desires advice from GLEANINGS readers.

Swanton, Vt., Dec. 17.

MRS. C. A. SIBLEY.

Our Homes

A. I. ROOT

What hath God wrought?—NUMBERS 23:23.

Lord, thou hast heard the desire of the humble; thou wilt prepare their heart; thou wilt cause thine ear to hear.—PS. 10:17.

[To the following fragmentary account of a trying experience with a new "talking" machine, an explanation is necessary. The dictaphone is a machine somewhat on the order of a common phonograph, which enables one to dictate letters on a wax cylinder which, later on, in another machine, gives a faithful reproduction of the record to an operator who writes it on a typewriter. In order to save A. I. Root's time and strength while he is in Florida, one of these mechanical stenographers was sent to him, the idea being that he could send the cylinders back to Medina to be typewritten. He did not realize how fragile the waxen records were, however, and so he did not pack as carefully as he should have done the first six that he sent. The result is that four of them were broken to "smithereens" in transit. Numbers two and three were intact, and "Our Homes" for this issue is the part of the story they tell.]

Since the first cylinder was broken, as well as numbers four, five, and six, we have no idea what text he selected; but in view of the fact that, in a note accompanying the cylinders, he was very enthusiastic over what he regarded as one of the new wonders of the age, we have an idea that he would like the ones which head this page. However, if he could have known that two-thirds of his work was to be lost outright because of broken cylinders we fancy that he might have added to it the third verse of the sixth Psalm.

There was some adjusting needed; and, as will be seen, the account starts right in the midst of the trouble he was having.—H. H. ROOT.]

As a great part of my life was spent in the watch-making and jewelry business I have been in the habit of handling delicate pieces of machinery and small tools. Very few necessities for this work, however, were to be found in our Florida home; and another thing, not only has my hearing failed more or less, but my eyesight also. Then the fingers of my right hand that has served me so skillfully for years past were also getting more clumsy and unwieldy than they were forty years ago. Notwithstanding, in a little time I succeeded in getting the machine apart and in managing the electrical attachment so that I got along fairly well. Very soon the carriage which travels over the cylinder refused to move. In order to remedy this I had to pull the machine apart still further, and I puzzled several days over the problem of finding a screw or something else that would let it come apart. Finally I told Mrs. Root that I could neither eat nor sleep until I found out what the trouble was with the dictaphone; and in order to get at this trouble it must be pulled to pieces.

I was still puzzling over it until bedtime when Mrs. Root came into the room and suggested it was time to kneel down, and

asked if I wanted to stop just then. As I was getting to be more or less vexed and impatient because I wasn't making any progress, my first impulse was to say that I hadn't time just then. On further reflection, however, it occurred to me that it was just the time of all times that I needed to kneel down and ask the dear Savior not only to give me patience but skill and understanding in the work that puzzled me so much. So we knelt together, and I prayed over just this one thing and nothing else. (By the way, friends, let me stop right here to remark that, though it is right and proper to pray for our nation or country or neighbors or relatives and many other things, when in trouble I have found relief by making just one petition, and nothing else, and ending it up with my little prayer, "Lord, help.") As we arose from our knees the dear wife, as a matter of course, asked if she could help in any way. I told her that there was a pair of eye-glasses for very close vision that I had used in testing eggs, but they had been lost some time. If I had those glasses I thought I might be able to see in the machine by the aid of the electric light, and find how it might be taken apart. In a little while she produced the needed eye-glasses from an old desk, and almost the first thing when I arose from my knees I discovered, with the aid of these glasses and the strong electric light, a little bit of screw, smaller than a pin-head, away down in the depths of the machinery. I said to myself, "Surely it can not be possible that this little screw releases the machinery so it will come apart." Now, I had no small screwdriver, such as watchmakers use, with which to remove the screw, nor had I any tweezers to pick it up when released—or at least I thought at first that I had none. I wondered if this little screw would happen to be loose enough so that I could turn it out with the point of my knife. It was loose, and in a little time I had it out so that I could get it if I had the proper tool. Then I thought of a pair of tweezers that we used for some time a year ago or more for pulling out stick-fleas. (I am glad to tell you that not a stick-tight flea has shown itself this winter so far, either on ourselves or in any of the poultry-yards. They have been vanquished completely by our heroic treatment, which seems the proper means to rid ourselves of this insect pest.) With the aid of these tweezers I soon had the little screw safely deposited

on the table of my secretary. And, sure enough, this permitted a part of the whole shaft to come off. Then was revealed a larger screw that could be turned out, letting the whole thing come to pieces. My prayer was answered. I very soon found the trouble with the machine, and the reason why it would not move the cylinder. There was a little screw that was not turned up tight enough.

Let me pause a little right here. In this day and age of wonderful progress, every one who is at all desirous of being up with the times must have more or less to do with this new and complicated machinery; and whether it be the automobile, the mowing-machine, reaper, or even the up-to-date dictaphone, it behooves us all to know if possible in regard to these wonderful labor-saving implements; and it behooves us also to be able to undertake to remedy minor difficulties. Now, after many years of experience let me give you a few suggestions before you try to take any complicated machine to pieces, whether it be an automobile, mower, or reaper. Be sure that you have all the available tools gathered together that you will need. Then get a clean piece of paper or newspaper, if nothing else is handy, and lay your tools on this paper; and when you commence taking the machine apart, lay the different parts, as you take them off, down on the paper where they can not be lost, misplaced, nor dropped in the weeds. When you are at work with agricultural implements out in the field this is especially advisable. Some farmers have a fashion of having the handles of their tools painted red so that, if they are laid on the ground or in the grass, they are more readily discernible because the bright red quickly catches the eye, and I have found this to be an excellent suggestion. But, no matter how much you are hurried, do not under any circumstances get into the fashion of dropping nuts or bolts down in the grass, weeds, dirt, or rubbish that may be around where you happen to be making repairs. I have seen quite expensive delays caused by this piece of carelessness.

Not long ago a skillful mechanic was called upon to repair a reaper, and he was obliged to go out by the roadside in the grass and dirt. He did his work in a workmanlike manner, and the owner of the machine started off with it; but after he had been gone some time we found in the grass and weeds several important washers which had been laid down and carelessly forgotten. It often happens that a good mechanic may do more harm than he does good; but it is seldom that you find a man or a firm

who is willing to pay for such loss by stupid, careless, or heedless workmen.

Let us now go back to the dictaphone. A washer slipped out of my clumsy and tired fingers, and it went jingling down on the floor under my secretary. It was already after my bedtime, and I was nervous and fidgety. But while I was hunting on hands and knees, Mrs. Root called and wanted to know what progress I was making. I had to tell her of the loss of the washer. She got up immediately and came and helped me. We looked all around the secretary, moved the rugs, shook them out, and went as far from the table as we thought the little washer could possibly have rolled, but without success. I was tired and worried, and almost ready to feel vexed and impatient, and finally that little short prayer of mine rang out, "Lord, help." In an instant Mrs. Root came up before me with her face shining, and held up the little washer that had made so much trouble. It was put back in place, and the machine was apparently all right. Now all that we needed to wait for was the mouth-piece and rubber tube. The next day, it was not until evening that I got time to test the machine once more. Almost with trembling hands I put every thing in the proper position and waited anxiously to hear it talk back. But again I was doomed to disappointment. There was no word, no sound. I talked louder, but with no avail. Mrs. Root was over at the neighbors, and I knelt down again and asked the dear Savior to instruct me once more and help me out of my trouble. Then I got up and tried it once more, and shouted "Hello!" until I feared I might disturb the neighbors. In response to this my heart was rejoiced by a faint "Hello." Then Satan or somebody else tempted me to think that I was too deaf to use a dictaphone any way. What did it mean? If the dear Savior had helped me the night before, was it possible that he should disappoint me in this way when I had gotten so far along? Then I remembered the blind man who was healed, and replied to his friends that he saw men walking about as trees. He applied to the Savior again and again. The Master touched his still imperfect eyelids, and then he went his way rejoicing, because he could see plainly his friends and neighbors and beautiful trees. I knelt down once more and said, "Lord, I believe. Help thou my unbelief." I then remembered that other text about the friends—how the Savior gently remonstrated with his followers because they could not understand or comprehend after the repeated miracles they had wit-

nessed. They were still lacking in faith. Was my faith lacking? With renewed hope I started to investigate the machine once more. I got Huber's letter of instructions, and finally came to the conclusion that every thing was all right except that I did not have the speaking-tube, which had not yet come.

Whosoever therefore shall be ashamed of me and of my words in this adulterous and sinful generation, of him also shall the Son of man be ashamed when he cometh in the glory of his Father with the holy angels.—MARK 8:38.

Let yo'r light so shine before men that they may see your good works, and glorify your Father which is in heaven.—MATT. 5:16.

He that goeth forth and weepeth, bearing precious seed, shall doubtless come again with rejoicing, bringing his sheaves with him.—PSALM 126:6.

SOMETHING GOOD FROM A LOCOMOTIVE FIREMAN.

I am much pleased with your paper, and only wish that I could afford it for a year; but will take advantage of your six-months' offer, and may be by that time I can renew for a year. I do like the way you write under the heading of Our Homes. If Christian men and women would use their influence more in their every-day life, humanity would be greatly helped. Many Christians are like the young man who joined the church and then got a job out west in a lumber-camp. Before leaving home some of the elders in his church told him that he would be thrown among bad and rough men while away, but that, if he would trust in God, he would have no trouble. He went away, and in about a year he came home. His pastor asked him how he got on out west. He said he did not have any trouble at all, as they didn't even find out that he was a Christian.

I wonder if our daily associates know that we are Christians? Let us not be ashamed of Christ under any circumstances. Let us not forget the great liquor curse, the white-slave traffic, etc.

I am a locomotive fireman, and live in the city. I have eleven lots, 40x120. On one we have our small five-room home. In the back yard we have peach, apple, pear, and plum trees, all bearing. My wife looks after the flowers and three colonies of bees and also the chickens. The bees are a cross between the black and Italian. This year we got over 300 lbs. of fine honey. I do not know much about bees, but am learning something more each year about them.

St. Joseph, Mo., Oct. 25.

X. T. CRAGUN.

May the Lord be praised, dear friend, that we have at least one locomotive fireman who is not only a Christian but one who is not afraid or ashamed to show his colors; I suppose, therefore, that your boss engineer never uses a bad word toward you, and certainly you never use any bad words in his presence (nor out of it either). I once rode for an hour or two in a caboose where scripture texts were tacked up on the walls. I found the freight conductor was a professing Christian, and asked him about swearing on his train. He said, "Mr. Root, I never swear at my men, and they never swear at anybody nor at any

thing—at least not in my presence or hearing." That was years ago; and I hope and have reason to believe that railroad men, especially the men to whom I refer, while at work loading and unloading freight, are of a higher type than they were a few years ago. These rough helpers in railroad traffic have not only severe hard work, especially when the train is behind time, but they have many provocations, and they certainly need the grace of God in their hearts if anybody does. The Y. M. C. A. has been making a special effort, as you may know, to look after these men. They are giving them clean beds, good and nourishing food, and at a less price than they formerly paid at saloon hotels. May God be praised for what the Y. M. C. A. has done. While we are sending vast sums of money to support and keep at work foreign missionaries, I have wondered sometimes whether we were doing missionary work that *needs* to be done in our own land, and oftentimes in our own homes. When I scrape acquaintance with these men covered with coal dust, and soot all over their overalls and jackets they often seem surprised to be recognized as men and brothers even despite their uncouth environment. When we recognize how many of these men are killed year after year, often through no fault of their own, especially while they are straining every nerve to take care of the traveling public and of the farmers' produce, shall we not improve every opportunity to give them a kind word of encouragement?

This brother has a little home with a back yard where he has a garden, fruit-trees, and some bees. The good wife has a busy time in looking after and caring for things around their home during her husband's absence for so many hours each day. I believe the Interstate Commerce Commission has interposed, requiring that these men work only so many hours a day. Often during an emergency they work over-hours and even during the night time.

In our haste to get around quickly and get our produce to market, getting our needed tools and supplies promptly, etc., let us not forget this army of workers who make it *possible* for us to live and have all the comforts of life during this twentieth century.

Once more, before closing, may we have grace and courage, each and all, who profess to be followers of the Lord Jesus Christ, to let our light shine in a reasonable and sensible way, no matter where we are. Of course no one expects you to go out of your way so much as to boast

that you are a member of the church. The scriptures enjoin us to be diligent in season; and not only that, but even out of season. May God bless the good brother who has by his letter braced us up where many of us need a bracing. I for one need it myself. And his message comes to me just before I am starting to my southern home. A great many times in traveling I feel too tired or worn out to open up conversation, say with the tired neighbors around me on every side; but some of the pleasantest acquaintances I have ever been fortunate enough to make have been opened up while taking a long trip somewhere. In after years I frequently meet these people, and it is one of my happy experiences to recount the incidents of travel of years ago. Away off in California I dropped a letter in the box, having my printed address on the envelope. The postmaster happened to be near and said, smilingly,

"Mr. Root, how does it come that you are sending letters to *yourself*?" Then he told of having passed a part of the night with me on a trip through the mountains years before.

Now, if you will take a little pains to get acquainted with your fellow-travelers there will almost always be a chance to put in a word for the dear Master, and you can do it, too, without being thought cranky or a little off in the upper story. Several times I have been enabled to get a promise from an acquaintance of only a few hours, that, when he got home, he would hunt up the pastor of the nearest church, and at least encourage him by being on hand at church or Sunday-school or both; and what a thrill it gives me when, years after, and I had forgotten all about it, to find from some pastor that my talk was the means of enabling *him* to gather in the "precious sheaves."

Poultry Department

MUSTARD FOR POULTRY.

We clip below from the *Illustrated Poultry Record* (English):

About two years ago six pullets were placed in competition with two other pens of birds numbering six each, and sisters to them. The first pen were fed on ordinary foods, the second on similar foods with an addition of capsicum, and the third pen also on similar foods, but with an addition of one teaspoonful of Colman's mustard. The mustard-fed birds laid during the period of six months commencing in October and ending in March the grand total of 532 eggs against 359 and 399 produced by the plainly dieted and capsicum-fed birds respectively. In this way did Mr. Ralph R. Allen, poultry lecturer to the Herts County Council, prove to the public that mustard-fed birds produce a larger supply of eggs.

Later he proved that the feeding with mustard in no way debilitates the birds. He produced a short brochure entitled "Mustard for Poultry," followed twelve months later by a booklet giving 101 reasons why mustard should be employed during the winter months to increase production. Mr. Allen has now issued a third brochure entitled "Enquire within upon Poultry and Egg Production," containing many valuable hints on practical poultry-keeping. The book is well thought out and well compiled.

From the above it would appear the six pullets were given a teaspoonful of mustard *daily*, for six months, which is a much larger "dose" than we have ever fed. So far I have never seen any unfavorable report from the use of mustard.

WHERE TO GET MUSTARD BRAN.

I notice in *GLEANINGS* for Nov. 15, in the Poultry Department, a suggestion for feeding mustard to poultry. The question is also asked whether some one can not advertise and furnish "poultry mustard" at a considerably smaller price than the ground mustard of commerce. I notice in the *Poultry Fancier* for December, a journal edited by

F. W. Delancy, Sellersville, Pa., an advertisement from Juniata Poultry Plant, Lewiston, Pa., in which a mustard bran is offered for sale. I believe mustard is better for poultry than cayenne or red pepper and many patent poultry powders.

Derry, Pa.

LAWRENCE L. PECK.

KEEPING POULTRY AT ONE-FOURTH CENT PER HEAD PER DAY.

Mr. Arthur Head wishes some details of feed and prices in this case. He would like "to know how it is done." It would be simple enough to give the bookkeeping details of this feeding, but I am now forty miles away from that yard, and have not been near it for two years, and did not carry away such details with me. The place was worked on shares; and as the owner was a pretty tight-fisted individual you may be sure he did not make the cost of feed any lower than it actually was. The accounts were checked monthly by two independent parties. It should be noted, however, that dry-mash or hopper feeding of any kind was tabooed. All fowls were hand-fed; all feed was carefully calculated and measured, and there was absolutely no waste of mash or grain. There was no waste by overfeeding the birds, and there was no waste by food going bad or by the birds scattering mash among the litter, or by supporting rats or other vermin. Any system that allows birds to gorge themselves at all times will soon run up the costs; and this is one reason why hand-feeding can walk all round dry-mash feeding. Animal food was economically bought. A local butcher supplied meat without bones at two cents a pound, and another butcher supplied bones for grinding at sixty cents per hundred pounds. This was rather different from buying meat meal (mostly ground bone) at \$3.00 per hundred pounds. As the meat was always fresh, pure, and sweet it was worth 50 per cent more in actual practice than the old horse meats mostly sold, and this in itself is an immense saving, apart from the actual prices paid. Little or no green food was purchased except oats used for sprouting to feed brooder chicks. The real economy lay in feeding the stock just as much as it needed, and absolutely wasting nothing

in any other way. Grain was bought from the ordinary supply houses at ordinary prices; but it was carefully examined for quality, and bought only from the firm that gave the best value for the money. Fowls were healthy and in good condition, and in the breeding season Leghorns and Minorcas gave eggs 85 to 90 per cent fertile. No grit was ever purchased, as we had a gravel-pit on the place which met all our needs for young and old stock. There were small economies in other directions which totaled to a tidy sum at the end of the year.

In this connection it might be useful to remember that in Britain two cents per week per head is the usual cost allowance for feeding a hen, and grain is generally dearer there than in America, especially corn (maize). But friend Head must be reminded that no method or system of feeding, however good, will of itself keep down cost. The man on the job is the only person who can do that in a poultry-yard. Victory depends not so much on the gun as on the man behind it. He is the key to the situation.

Philadelphia, Pa.

FREDERICK MARTIN.

SHALL WE KILL OFF ALL HAWKS INDISCRIMINATELY BECAUSE SOME OF THEM "KILL CHICKENS"?

Mr. Root:—Inasmuch as you published in your department a column letter devoted to the most unreasonable criticism of Dr. A. E. Fisher and myself, and then followed it with your own endorsement (page 751, 1909), I wish to present to you the evidence, just now published, on which my defense of the hawks is based. I never have defended all species of hawks indiscriminately, and I was surprised that, with your usual spirit of fairness, you should give your endorsement to such an article, especially when the writer's own language showed that his conviction was based on his prejudice rather than on an investigation of the subject. Dr. Fisher stands high as a scientist, and those who are making such vigorous attacks upon him are, without exception, men who have made no investigation of the subject, and thus expose their own ignorance. The average person does not know one hawk from another, and there is prejudice enough against them without a journal with such a wide influence as yours adding to it. I feel that, after giving the weeks of time necessary to carry out this investigation, the evidence gathered ought to carry some weight against a fellow who manifestly knows nothing of birds of prey further than that he has seen a hawk kill chickens.

Let me say that I have read your department with pleasure for years, and enjoyed it too. Whenever I come in contact with beekeepers I hear good words, not only for the magazine as a whole, but for your department especially. I am glad for its influence, and for the fact that you have endeavored to use your influence always for the right.

FRANK C. PELLETT, Inspector.

Office of State Bee Inspector, Atlantic, Ia., Nov. 12.

I hereby apologize to friend Pellett. Where a hawk has "acquired the habit" of killing chickens, no doubt it should be killed; but our best authorities are of late coming to the conclusion that we often find ourselves in a worse fix when we hastily carry the war of extermination too far. Witness the history of sweet clover, etc.

HOW HOT DOES IT GET IN FLORIDA?

I notice in GLEANINGS that D. W. Abbott says that on Oct. 15 it was 95 at 5 P. M., and 89 at 7:30. This may give your readers the impression that we are living very close to Hades. Now, Ten Broeck says in the journal that on that day the minimum

was 72 and maximum 88. Who is right? I should say Ten Broeck. I don't think the thermometer has been higher than 94 all this summer.

Bradentown, Fla., Nov. 11. J. W. BANNEHR.

Our readers will notice that there is a disagreement in the above of 6 degrees. Our neighbor Ten Broeck is a government weather reporter; has standard government instruments, and is probably very nearly correct; but as he is himself just now "under the weather" he may not have noted the warmest record of the day in question. Another thing: At one time we had our thermometer hanging in the woodshed; and as it didn't agree with his we gave him notice, and he directed us to place our instrument on the north wall of our house. This made quite a difference. Friend Abbott is out in woods, or clearing, rather, about two miles from here, and he may not have had a standard instrument.

Now, there is just one more thing to add. People who live here, especially if they have real estate to sell, are very backward, as a rule, in admitting any thing derogatory to their locality, such as "redbugs" and other insect pests, for example.

Many thanks to my good friend Bannehr for calling our attention to the matter.

"STOP SENDING YOUR PAPER."

The following letter explains itself:

Dear Sirs:—Please stop sending your paper. I do not want to be insulted every time I get a copy of it. I am drinking and smoking, and I like it, and do not feel like paying for any thing that is against my pleasure and the liberty of the land.

Big Wells, Texas, Sept. 28.

E. ZIEGAST.

With the great mass of kind words that come like snowflakes from January till December, once in a while we get something like the above. The good brother who writes it evidently comes from foreign shores. We judge so by his name and also because he seems to think the crusade for temperance is a restraint on "personal liberty." We are sorry to part company with him; but judging from past experience we think the time may come when he will feel like saying, if he does not say it right out, "Brother Root, I am convinced now that you were right and I was wrong."

A DOCTOR WHO HAS NO USE FOR ALCOHOL.

I began the practice of medicine in 1866; was taught that alcohol is a stimulant, and used it for several years, but always with disappointment, and quit its use entirely for other means from which I could see stimulating effects which I never saw from alcohol. "Wine is a mocker, and whosoever is deceived thereby is not wise."

NO 3

Editorial

THE MEETING OF FOUL-BROOD INSPECTORS.

The second meeting of the foul-brood inspectors of the various States was held in Cleveland, Dec. 31, in conjunction with the meeting of the American Association for the Advancement of Science and the affiliated societies, for the purpose of forming a permanent organization. Steps were taken to perfect such an organization, the same to be a part of the larger body already mentioned. Full particulars will be given later by the Secretary, Dr. E. F. Phillips.

NO ADULTERATION FOUND IN CONNECTICUT.

It is a significant fact that, according to the report of the Connecticut Agricultural Experiment Station (Part 2 of the Annual Report of 1912), no adulteration was found in twenty-six samples of bottled honey examined. The following is the first paragraph of the summary:

While in a few cases certain tests indicate the presence of a small amount of glucose, and in two instances the percentage of ash exceeds the standard, we do not feel justified in condemning any sample as adulterated or otherwise illegal. There are wide variations in quality, but all the samples appear to be genuine honeys of varying origins.

A FOUL-BROOD INSPECTOR AND A LECTURER.

MR. FRANK C. PELLETT, of Atlantic City, Ia., State Foul-brood Inspector, is also a lecturer of some note. He is employed by two lecture bureaus. Some of his principal themes are as follows: Little Giants; Economy of Nature in the Plan of Eden; Our Backdoor Neighbors; Passing of the Red Man; Bees; Religion of the Indians; Lives of the Four-footed; Short Course in Nature Study. This last consists of a series of lectures that are both popular and interesting. Mr. Pellet is a naturalist as well as a bee-keeper, and Iowa was fortunate in securing a man of that sort for inspector.

WHY HONEY HAD A GREATER BUYING VALUE FORTY YEARS AGO.

ELSEWHERE in this issue two of our correspondents allude to the fact that honey sold for a much higher price years ago, and that it really was higher in price compared to other articles. Mr. Doolittle suggests

that this can hardly be accounted for by over-production, which is probably true, since the demand also has increased enormously. But it occurs to us that granulated sugar, maple syrup, glucose (or the so-called corn syrup), canned vegetables, and fruits have all combined to furnish a variety and very often a substitute for honey. Moreover, transportation facilities have improved so greatly in forty years that fruits of all kinds are much more widely produced and distributed than in the olden days; so that honey, the purest and most healthful sweet, has really been reduced in price by the competition of other foods.

It is also true that no organization of producers has yet done any extensive advertising along the line of popularizing the use of honey.

A. I. ROOT'S FIRST EXPERIENCE IN BRIMSTONING A BOX HIVE; HOW IT NEARLY COST HIM HIS LIFE.

In this issue, A. I. Root, in a reminiscent way, tells how he first began keeping bees; and among other things he writes about a box hive that was to be brimstoned in the dead of winter; how his childish eagerness was such that he went out into the cold air when he was already sick with a cold, came down with pneumonia, and for days hovered between life and death. Had he been taken away, some history would never have been written; there never would have been a Home of the Honeybees, no GLEANINGS IN BEE CULTURE at Medina, and possibly the beekeeping industry might not have been advanced to its present status. The doctors did not save him; but his mother (as the neighbors said) "would not let him die."

NOVICE'S GLEANINGS IN BEE CULTURE.

Our cover picture for this issue is a copy of the first engraving that ever appeared on the cover of GLEANINGS; and, as will be noticed from the inscription underneath, it was "Designed and engraved by Novice" (A. I. Root), and with a saw.

Some idea of the change that has taken place in forty years is gained from the fact

that GLEANINGS was first issued as a quarterly of only eight pages, 6 x 9½. It was immediately changed to a monthly of fifteen pages, the last column of which was reserved for advertisements, there being seven in all.

Among the names of beekeepers seen in this first volume of GLEANINGS we find the following who are known to the beekeepers of to-day: C. C. Miller, G. M. Doolittle, E. Kretschmer, C. P. Dadant.

Is it not a significant fact that all four of these writers have made contributions for this special Old Timers' number after a lapse of forty years? We are proud of the fact that A. I. Root, the founder, while no longer the managing editor, is still, nevertheless, editor-in-chief.

WINTERING DOUBLE-WALLED HIVES IN THE CELLAR.

MOST of our bees we winter out of doors. This was the case unfortunately last winter; but there was one yard of Carniolans, the individual colonies of which were not very strong, as they had been made up of nuclei comparatively late in the season. We had more fears of this yard than of any other that we had. When the severely cold weather came on, we feared that they would not winter, and so we brought them home and put them in the cellar—double-walled hives and all. When we set them out in the spring they were the best and strongest apiary we had; and if we had put our other bees into the cellar we should not have been obliged to buy heavily in the spring; for while our losses outdoors rarely exceed 5 per cent, last winter they went up to over ten times that. Hereafter, when a severely cold winter comes on, we shall put our bees all in the cellar, and set them out early the following spring, or as soon as severely cold weather lets up.

MOVING BEE-YARDS IN THE HEIGHT OF WINTER WHEN SNOW IS ON THE GROUND; SNOW MORE EFFECTIVE THAN SMOKE FOR QUIETING BEES IN COLD WEATHER.

As mentioned in our last issue, we have been moving some of our apiaries, located in exposed regions where the windsweep was too strong for best results in wintering, to our mammoth bee-cellar made of concrete and brick. It has formerly been considered that it was not wise to move bees in midwinter, as the disturbance would cause them to become active, consume their stores, and clog their intestines, with the result that dysentery would set in before spring. Our experience last winter and this leads

us to believe that this is not so. If the weather is cold enough, the bees will not be greatly disturbed. We prefer a temperature anywhere from 10 to 25 degrees above zero. There should be at least fair sleighing in order to get the best results. When possible the time for moving should be selected right after a light dry snowfall, for reasons that will be presently explained.

If the roads are uneven, and show bare spots, a common old-fashioned sled with long runners is better than a pair of bobs. Whichever is used should have a large platform such as a hayrack, on which the hives may be loaded. The sled is to be pushed clear out into the middle of the apiary, and the team detached and blanketed. The hives are then loaded one by one. As many as sixty or seventy colonies can be carried on a sled. As it is low it is easy to load the bees. The entrances should be so arranged that the apiarist who accompanies the driver can easily get at them. The bottom-boards should be most securely fastened if they are of the loose type. Sometimes the sled will slip sideways, causing a sliding jolt that may dislodge one or more hives from the bottom unless they are well fastened. If they are piled up two tiers high they should be securely roped to the platform and hayrack.

A little way back we stated that the time set for moving should be right after a light snow. The purpose of this is to provide an easy and effective means for closing the entrances of the hives. A wet or soggy snow is too much of a good thing. If it is frozen hard, and breaks up into lumps, it does not make a good entrance-closer; but if it is light and fluffy, it can be picked by handfuls and thrown over the entrances of the hives just before loading. When all are on, the entrances should be examined again, and more snow used if any bees seem to be getting out. A pail or two of light snow should then be put on the sled, to be used in case of emergencies. In cold weather it is far more effective than smoke, and makes an excellent entrance-closer. The bees within can not cluster over the entrance—indeed, they fight shy of it, retreating back into the combs. If any colony should become very much excited by reason of a closed entrance, the heat will melt the snow automatically and thus give ventilation. But in the dead of winter there will be little or no trouble of this kind.

On arrival at the bee-cellar the sled is driven as near as possible to the cellarway. The bees are then taken up, hive by hive, and placed in their permanent location in the cellar. There is no need of removing

the snow over the entrances; for if the cellar is of the right temperature it will melt in a short time, or about the time the bees quiet down.

We find that a light snow is the most effective entrance-closer that we have ever used, and *the only thing fit to use during cold weather in winter*. The heat from the fire-cup of the smoker warms up the bees, stirring them up a good deal more than if smoke were not used. When the bees boil out at the entrance a few handfuls of light snow dropped gently over them drives them back. It is interesting to see them skedaddle back into the hive; for the snow has a tendency to cool them off. Whenever bees become cold they immediately seek the warmth of the cluster.

Last winter we moved an apiary during zero weather from what we then called our Nettleton yard, and placed them in the cellar. We never had bees winter nicer than they did, and in the spring they were the best and strongest lot of bees we had, notwithstanding that in the fall they were the weakest lot of bees—so weak that we felt that they must be put indoors.

THE HUMBLE-BEE: ITS LIFE HISTORY, AND HOW TO DOMESTICATE IT; BY F. W. L. SLADEN; ILLUSTRATED WITH PHOTOGRAPHS AND DRAWINGS BY THE AUTHOR, AND FIVE COLORED PLATES PHOTOGRAPHED DIRECT FROM NATURE.

This is one of the most interesting and beautiful books that have been put out for a decade. The author has obtained his information direct from nature. He explains how he has been able to decoy queen bumble-bees to start nesting under his care, and also how he has been able to get the colonies to work under glass in a specially constructed house where all the details of their behavior can be watched. In many ways the habits of bumble-bees seem to be intermediate between those of the solitary bees and of the honey-bee; but there are differences, and for their own particular purpose they have reached a high stage of perfection. The queen bumble-bee is highly "intelligent," and cares for her young as devotedly as a bird or a mammal. As the result of twenty years' intimate acquaintance with the bumble-bees, and with the aid of the decoying devices and special hives, the writer has been able in this work to present for the first time a great many new facts concerning the bumble-bee's habits. It was through the study of the bumble-bee that he was led to discover the true function of the auricle as an instrument for packing the

pollen into the corbicula box in the honey-bee and the bumble-bee. He shows, too, that the bumble-bee collects its wax from the abdomen or the bristles of the brush on the inner side of the metatarsus, or planta, of the hind legs. Casteel has since shown that the honey-bee also uses these bristles for the removal of wax, but only the row at the distal end of the metatarsus. (See *The Manipulation of the Wax Scales of the Honey-bee*, Circular No. 161, U. S. Dept. of Agriculture, Bureau of Entomology.)

The book discloses a new interest for country rambles, and is being warmly welcomed by the advocates of nature study. There is explained in full and clear detail how the nests of bumble-bees may be found and taken and set up again in the garden, and also how to make a collection of specimens and how to distinguish the British specimens. A different set of species occurs in America; but the methods by which the American species are separated may be applied to the American species; and to do this would help to stimulate the interest of the student. Some of the species resemble one another very closely; but there are slight differences in the tint and quality (length, density, and shagginess) of their furry coats. These differences are brought out very well in the colored plates which are among the very best reproductions of insects by photography in their natural colors that we have ever seen. Each species appears to have distinctive habits. Some live under ground in comparatively large colonies, with 200 or 300 workers, and will defend their nest, if disturbed, with great spirit. Others live on the surface of the ground, in communities not containing more than about 100 workers, which are very faint-hearted; and when the nest is molested they will feign death, and lie on their backs half hidden in the nest material, ready to seize and sting the fingers if they are touched. But the sting of the bumble-bee is not very severe, and it is used only under great provocation.

Bumble-bees are invaluable for fertilizing long-tubed flowers, such as red clover, for they alone of all the bees have tongues long enough to reach the nectar easily.

The book contains nearly 300 pages; is beautifully printed in large bold-faced type. We were told by some of the entomologists that recently met in Cleveland that this was undoubtedly the most complete work of any that has ever been written, and Mr. Sladen is regarded as an authority on the subject. We do know this: He has been gathering data for the last twenty years. Price \$3.25, postpaid, at this office.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

You ask, Mr. Editor, p. 4, for a way to mark a queen with a permanent color. In "Die Rassenzucht," Dr. U. Kramer, page 111, recommends a quickly drying lac—red, yellow, white, or blue—not so thin that it will run, and not so thick that it will not adhere. He gives full instruction as to the whole proceeding.

IN 1872—'3 I spent some months in Cincinnati helping in a subordinate way to get up the first May musical festival under the direction of Theodore Thomas. One day a quiet old gentleman came into my office to chat about bees. In spite of his modest demeanor he knew a lot about them. He was the Rev. L. L. Langstroth.

A. I. Root, do ye mind that time when we slept together in a western city at which there was a national bee convention? Next morning, as we walked along the street I was somewhat disconcerted to pull out of my pocket a night-cap. I made no use of night-caps, either the cloth or liquid kind; but I presently found out it had been put into my pocket inadvertently by the man who had slept with me.

NOTWITHSTANDING all the improvements that have been made in beekeeping, there's one thing that is no better in quality nor greater in quantity than it was 50 years ago. That's enthusiasm in the business. Young fellow, you think you're having a jolly good time learning all the up-to-date things in beekeeping. Well, we old codgers had just as good a time 50 years ago learning what was up-to-date at that time. Now hold right still while I tell you another thing. I've just as much fun now as I had 50 years ago in seeing what the bees will do to my plans after I've studied them out. So enthusiasm is a constant factor if you're a born beekeeper.

YE editor, p. 2, seems to have a desire that I should jab J. L. Byer for his views. All right; come on and be jabbed, Bro. Byer. You seem to hold, p. 6, that with solid combs of honey and nowhere else for the bees to cluster, bees will winter all right. That will leave the bees in layers $\frac{1}{4}$ inch thick between the combs; and if they *remain* with no better chance for clustering "during the weeks and weeks of cold zero weather," my guess is that they'll be dead. Your experiment will prove nothing, for, as ye editor suggests, the minute you stopped feeding them they began scooping out a winter nest. Moreover, you don't

say how much room they had to cluster under the bottom-bars. Surely more than $\frac{1}{4}$ inch. Editor Root holds that instinct makes the bees empty out a place to cluster. I suspect instinct makes them eat the honey, and that happens to leave the empty space. And I suspect that, if there was a possibility of keeping the combs constantly solid with honey, they would winter just as well without an empty cell in the hive. You say, "They can't warm up these slabs, because they project beyond the cluster where it is cold. These cold projections convey the cold back to the cluster." Say, Mr. Editor, did you ever see a solid comb project down through the cluster? Come down into my cellar and I'll show you the cluster of bees projecting down below the combs—two inches—but never a filled cell below the cluster. I don't know how small a space below the combs will answer for clustering; but I know that bees can cluster all right below bottom-bars, for I know my bees *do*. Theoretically one of you is just as far from my view of the truth as the other; but for practical purposes the Canuck holds the safer ground. Now, Mr. Editor, haven't I jabbed J. L. enough? [When you ask the question whether we ever saw a solid comb project down through the cluster, you are evidently thinking of indoor wintering. What we have had in mind all the time on the subject of winter nests has been *outdoor* wintering, and not indoor. As we said over a year ago, this question of the proper formation of a winter nest is not particularly important for indoor bees, especially if there be a large clustering-space under the frames such as you use in your cellar. But when bees are wintered outdoors, and the temperature outside (assuming it is a double wall) is 20 or 30 degrees higher, it is important, at least for our locality, to have a winter nest. If you could look over our outdoor-wintered colonies on a day when the temperature is about 10 degrees above zero, you would find that the combs in most cases project an inch or more below the cluster, and eight or ten inches beyond the cluster in the direction of the length of the hive. The point we tried to make was that solid combs of sealed stores that stick out beyond the bunch of bees into an atmosphere that is down to freezing, or below, will convey the cold clear through the cluster almost as badly as so many slabs of marble. The $\frac{1}{4}$ or $\frac{3}{8}$ inch of bees between the combs can not make up for this constant loss of heat.—ED.]

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

Nearly half an inch of rain fell on Jan. 9. We are hoping it may be the beginning of the end of our long dry spell.

* * *

The condition of bees in general in this State is about an average, judging from reports received up to date.

* * *

Black brood is still spreading in our Southland. Every beekeeper should know of its approach, and prepare to combat it.

* * *

The price of bees has materially advanced in recent years. There are now but few for sale at \$3.50 or less per colony, as was the case a few years ago.

* * *

Some time ago I predicted a warm wet winter; but there is where I missed my guess and ruined my reputation as a weather prophet, as most of our local observers do.

* * *

Several men in Riverside Co., who expected to ship their bees back from Utah, are not able to do so on account of alfalfa-weevil quarantine. Some who extracted closely in anticipation of moving now find that they must feed heavily.

* * *

While visiting T. O. and L. L. Andrews, at Corona, I saw an automobile equipped with an extracting-house. It was the first I had ever seen, and it gave me a better idea of the bee business as conducted on a large scale, with an auto as a mode of quick conveyance for taking extracting equipment to out-apiaries.

* * *

Early in September I visited a beekeeper, and during my conversation I mentioned the imminent danger of black brood. Perfectly astounded, he ripped out an oath, asking what that was. He owns in partnership nearly 600 colonies, but never has time to read a bee paper. He will probably know more of this disease some day.

* * *

I was interested in J. E. Crane's description of the many kinds of hives he found in his inspection work. My experience was much the same while traveling over the country the past season, with the exception of box and frameless hives. We have a law in this State compelling the use of movable frames, to enable the inspector to work promptly and rapidly.

Beekeepers are, as a rule, very poor advertisers. Go into almost any chamber of commerce in southern California, and if you see any display of honey at all it is not likely to be of much credit to the industry. Almost all other products are better represented than our own—not because a display of honey would not be welcomed by our commercial organizations, but just through neglect of beekeepers.

* * *

ANOTHER PLAN FOR LAYING-WORKER COLONIES.

Louis H. Scholl, p. 720, Nov. 15, give your laying-worker colony a frame of unsealed brood, then put it in the place of a strong colony. In 24 hours you will find cells started, and the laying workers and their brood will disappear. I have yet to hear of this plan having failed. I doubt, however, if it is profitable to try to save a laying-worker colony at that time of the year.

* * *

BREEDING FROM THE BEST WORKERS.

The practical ideas of practical men are worth much consideration, as is shown by results obtained. The practical work of A. T. Warr & Son, of whom I have made previous mention, in selecting their best producing colonies for breeding purposes is one such instance. While they favored the Italian blood as much as they could, the productive qualities were to be considered first. Owing to the advent of black brood in the community they are now forced to Italianize for their own protection; but it is safe to say that only the best producers will be used for breeding after the try-out.

* * *

APIARIES THAT CAN NOT BE REACHED BY AN AUTO.

Louis H. Scholl, page 579, Sept. 15, says: "The automobile is a sign of progressive beekeeping." Perhaps to a degree this is true; but Mr. Scholl should know that there are some apiaries that can not be reached by auto, the owners of which are progressive enough to keep on good ranges and get the honey first, regardless of the mode of conveyance to be used in going to and from the apiary. To them this is a secondary consideration. A few good seasons in succession would make many of us progressive in that way, while bad seasons might for ever bar us from that class.

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

Mr. Sladen, recently from England, gave a warning against importing any bees from the British isles for fear of getting Isle-of-Wight disease over here. Judging by what he and others who know say, this fell scourge has all the other bee ills "beaten to a frazzle." Certainly Mr. Sladen's warning is timely, and it would be a foolish thing indeed to take any chances.

* * *

Already "jabbed" by the editor, and with the prospect of being jabbed again by such a formidable assailant as Dr. Miller, is it any wonder that I look for the next issue of GLEANINGS with trepidation? (page 2, Jan. 1). But see here, Mr. Editor; you say something about steady cold weather about the "middle of January;" at which time enough honey will be consumed to give the colony a winter nest. Here in Ontario we often have that kind of weather all through December; so, what will happen when things pan out that way, and the combs yet solid with honey?

* * *

That article of Wesley Foster's on page 13, Jan. 1, which so entertainingly tells about the beauties of photography, I read with more interest than I could have deemed possible a few months ago. Can you guess the reason? Well, I have recently invested in a camera costing about \$20.00, an English machine called the "Butcher's Carbine." I never had my hands on a camera before; but by a strange freak of chance, the first six films used are all good, and I hope to use some of them soon in this journal. I have just returned home from the northern yard, over 100 miles away from home; and while there I took several pictures of the apiary to illustrate wintering outside. I have not tried to develop them yet; and on reading friend Foster's article I am fearful that I gave too long an exposure to the films. It is needless to say I shall find out just as soon as possible. Really I must stop writing along this line, else (before I know) I shall be classed as a "camera fiend" before I have even had a peep into the rudiments of the game.

* * *

LONGEVITY OF CARNIOLAN QUEENS.

On page 743, Nov. 15, the question is asked as to whether Carniolans are prone to supersede their queens; and in answer to this I must say no, most decidedly. As a matter of fact, I have often wished that such was the case, as one fault I have with them is that the queens are very long-lived, and will sometimes be left when they are

too old to be of good service. As I clip all my queens I know what I am talking about. No doubt claims are made sometimes by people who do not clip, so they can not be positive on matters of this kind. Some time ago I reported having kept a queen until she was seven years old—no doubt about the matter at all, as I have abundant evidence to prove the statement. Well, this particular queen was a pure Carniolan, and her wings were *all* off close to her back, so that there were additional risks according to some anti-clippers.

* * *

IS FOUL BROOD MORE VIRULENT AT TIMES?

On page 719, Nov. 15, Mr. Crane speaks of foul brood being more virulent in some places than in others, and says that he does not wonder at the variety of opinions expressed on the subject by different writers. What kind of foul brood is meant? If European foul brood I can understand how differences of opinion might arise; but if our old acquaintance American foul brood is meant, I can not agree with him. I have seen it in different counties in Ontario in all stages, and I can think of no malady affecting any living organism that is more uniform in its actions than this disease. As a general principle, it can be stated that larvæ die from this disease only when fed infected honey, or what amounts to the same thing, when a larva is hatched in a cell that has the disease scales, and thus becomes infected. Disease makes progress according to the number of larvæ that happen to get the disease given to them. As an illustration, the following will make the point clear; and as it is a common happening in sections where American foul brood is present, no doubt many have noticed how it works.

Let a colony that is foul be robbed out late in the fall when brood-rearing has stopped, and as a result it may be that none of the robbers will cause disease to break out in their colonies, for the simple reason that no brood is present and the honey is used before any larvæ are in evidence to be fed this diseased honey. On the other hand, let an apiary rob out a foul colony in the spring time, especially just at the close of fruit bloom, and every colony taking part in the robbing will be diseased—nothing surer. The same principle on a modified scale applies to all stages of the disease, and will always explain why a colony gets bad very quickly in one case, while another may have had the disease for quite a while before getting in bad order.

Conversations with Doolittle

At Borodino, New York.

YE OLDEN TIMES.

A correspondent writes. "If Doolittle does not have something February 1st about 'Ye Olden Times' in beekeeping I shall be greatly disappointed."

My memory goes back to the days when father kept bees in box hives, and to log-gum times. In that age fifteen and twenty pound boxes for comb honey were made of rough half-inch lumber with a hole bored in one side, over which was placed a piece of glass broken from a window pane through which I, as a boy, would peer to see whether any honey was being built. Usually I did not even see a bee inside. It had to be a good season to drive the bees into these boxes, for in most cases there was only one auger-hole, an inch or an inch and a half in diameter, through the top-board to the hive. This board was of about the same thickness, and the big empty honey-box was without any starter of comb. From our standpoint of to-day, this would be a great drawback; but, strange as it may appear, during one season father took as much as 70 pounds of comb honey from one of these rough hive boxes in which were hived two swarms which came out and clustered together. A few years later the lumber for these boxes was planed on the inside, and a piece of white comb stuck fast to the center of the top. This greatly promoted the willingness of the bees to enter the honey-receptacles. However, few of the farmers did little else than hive swarms in old boxes, portions of hollow logs, half-barrels, or nail-kegs, in those times of 60 to 80 years ago.

Then all colonies not needed for wintering were killed by setting the hives over fumes of burning sulphur. After the bees were dead, the hives were pried apart, or the old logs split open and the combs of honey cut out. In this way from each hive or log twenty to fifty pounds of honey were obtained, the best and whitest of which was put into bright tin pans to be disposed of, while all of the rest was put into a cloth bag and hung up before the fireplace to drain out as strained honey. After practically all the honey had drained out, the bag was immersed in water, as hot as the hand could bear, and the whole was kneaded and worked over with the pudding-stick till all the sweet had been separated from the comb. This sweetened water was boiled down to honey water. It was then used to sweeten apple sauce or pies. In these different ways much pleasure and enjoyment

was given to the family of the farmers who kept bees.

When I began to keep bees in the latter sixties, Langstroth hives were beginning to supersede the old logs and boxes. These were thought to be the height of perfection, for each had a honey-board on which were placed six boxes six inches square by five inches deep, each having a glass on two sides, the glass being on opposite sides. Before the glass was put on, three pieces of comb were stuck to the top of each box equal distances apart, to be used by the bees as guides for building their combs in a certain direction, as well as for starters. In this way I procured my honey for the first three years. I used these boxes more or less till 1875. They held from six to six and one-half pounds, gross weight, and, strange to say, I was offered 50 cents a pound for my 1869 crop.

After these came the four-pound box with its four metal corner posts and four glass sides. This box was considered the most fancy honey-receptacle that ever was, as two sides showed the nice white capping of the honey while the other two showed its color and quality, where the cells were stuck to the glass. I doubt if there were ever more attractive packages, when filled with honey, than these glass honey-boxes with their shiny metal corner-posts.

A few years later came the Harbison three-pound box, then the two-pound section, which was soon followed by sections holding one pound—some even going so far as to make those holding as little as a half and a quarter of a pound. Both of these, however, proved to be too small for any profit, so that the one-pound section soon became the standard, and has held that place until the present time.

I might speak of many things which would now be considered drawbacks, which came about in the transition between those old times and the present. Then we did the best we could without sections, queen-excluders, bee-escapes, movable frames, comb foundation, extractors, etc.

But I wish to speak of something which seems a mystery to me. In all of those years honey brought much more in return to the producer than it does in this, the twentieth century. Father used to trade that cut comb honey, from those bright tin pans, giving 12 to 18 pounds for a pair of shoes, according to the quality of the shoes and that of the honey. Then he could get a bushel of wheat for four pounds of this

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

INTERSTATE SHIPMENT OF DISEASED BEES.

Mr. Chadwick asks whether the bees spoken of as having been kept from being shipped into Colorado were known to be diseased. No, we did not know, except that the district where the bees are is known to be diseased. We did not try to stop the shipment by law, for one State can not legislate against another. All that was done was to notify the party of the conditions that prevailed where the shipment was intended to be made, stating that we would inspect the bees upon arrival. I do not believe that the county ordinances such as Mr. Chadwick speaks of would hold very many minutes under the rulings of the Inter-State Commerce Commission. A beekeeper would have to submit to inspection after arrival; but I do not believe that the shipment could be stopped unless the bees were known to be diseased. Our Colorado law is broad enough so that I think an inspector would be upheld in destroying all diseased bees upon arrival. This would not be just unless the disease was being introduced into a clean district. In a district where foul brood already exists, the man who shipped in bees, and a few were found diseased, should be accorded the same treatment that others in the vicinity are given.

Colorado at the present time has no European foul brood that we know of, and the beekeepers here would be very much in favor of destroying all colonies in a shipment that had this disease; and our law would stand back of the procedure. I do not think that such measures for the protection of bees from diseases are unjust. The good of the whole beekeeping fraternity is of more consequence than the desires of some unenlightened individual. Far more damage has been done by the indiscriminate shipping of diseased bees all over the country than by stringent laws that may seem to work a hardship on any one person. We must encourage in every way the legitimate spread of aggressive beekeeping methods; but the spreading of diseases must be curtailed also.

* * *

THE EFFECT OF TARIFF REDUCTION ON PRICES.

Local business houses are making increased efforts to clear their shelves of all stocks bought under present price conditions. Business men seem to be optimistic, but expect a readjustment of prices after the Democratic administration has begun its work at tariff reduction; and when the tariff is men-

tioned, the beekeeper immediately thinks of free sugar, and whether honey will be put on the free list. And the next commodity thought of is lumber. I do not know what will be done with honey; but the talk is strongly for free sugar, and perhaps the admission of lumber free of duty. Personally I believe that free sugar will aid rather than hurt the beemen. This will depend, of course, on whether sugar is reduced to the consumer by taking off the tariff. If we could get sugar for three cents instead of five or five and a half, much more of it would be fed in the fall to put the bees in prime condition for wintering. Being situated so far inland, and not familiar with the markets where foreign honey would cut a figure, I do not know what the effect would be if honey were put on the free list.

Lumber admitted free ought to have a definite effect on the price of bee-supplies; and it might be that the quality of the lumber obtainable would be improved. Taking the whole situation, I think that the beemen will not be averse to the general plans for tariff revision. What we are concerned in is a reduction in the cost of necessities for the home and in our business. One of the greatest promises of the times is that the people as a whole are asking for something definite—stated, not in political terms, such as tariff revision, but in terms of economics—a lower price for sugar, lumber, woolen and cotton goods, and all staples that consume the bulk of our incomes.

CONVERSATIONS WITH DOOLITTLE AT BORODINO, NEW YORK

Continued from page 77.

honey, and trade even-handed pound for pound for butter. And in the days of the six-pound box, I sold my whole crop to a dealer for 26 cents a pound, taking him four wagonloads, and on my return home loaded these wagons with coal at our nearest station, \$3.50 a ton. Now it takes nearly four pounds of honey to purchase what one pound did when father kept bees; and our nice section honey in one-pound sections, when sold by the wagonload, brings only 12½ cents instead of 26. Now a wagonload of coal costs \$6.80 at the same place where the \$3.50 coal was obtained in the days when beekeeping was carried on in a more primitive way. This state of affairs can hardly be laid to overproduction, as I verily believe that the per-capita consumption in those days was two if not three times as large as it is to-day.

General Correspondence

THE FUN THE PIONEERS HAD IN INVENTING NEW FIXTURES

A Bee-smoker Made of a Pan of Coals

BY DR. C. C. MILLER

How I'd like to go back and begin bee-keeping all over again with the facilities of the present day! Back yonder in 1861 the bill of fare was rather meager—no extractor, no smoker, no sections, no comb foundation, no excluder, and almost no literature. Movable combs had been invented, but I knew nothing about them. *The American Bee Journal* was started that year, but I didn't know of it. And yet I don't know. You who start in with all these things don't have the same pleasure I had in learning about each one as a new improvement. And then the lots of new plans and kinks that have been coming up all the time!

One thing, however, I'd like to have back again. I'd like to have honey keeping all the while at the same price as butter. It would seem pretty good now to have honey selling at 30 or 40 cents a pound. Another good thing of those bygone days was the delight of studying up some new plan or implement, lying awake at night thinking it over. Honey may never catch up with butter again in price, but the fun of studying up new things is just as great now as it was back yonder. In any given case there is always the zest that is given to it by the uncertainty as to what the bees will do with it when it is submitted to them. Even after being submitted to them there is the uncertainty as to whether they will do exactly the same next time, when conditions may be a trifle different.

The first surplus honey I produced was just as good to eat as any I produce now—just as white, but not so regular. A box with a capacity of five or six pounds, with a pane of glass on two opposite sides, was placed along with three others on top of a box hive, with a cover telescoping over it. Such a box, when filled, seemed just as pleasing a sight as the finest sections do nowadays. By way of something extra I had some boxes with four glass sides and wooden posts at the corners. The bees built comb in these boxes at their own sweet will except for the persuasion of a few pieces of comb fastened to the top of the box. If one or all of these starters fell to the bottom, the bees were not greatly disconcerted. They simply built from the bottom up.

This was quite in advance of what some

others were doing, whose only way to secure surplus was to brimstone a colony, and then dig out as well as might be the honey mixed with pollen and dead bees. The heaviest and the lightest skeps were "taken up," the heaviest because they had the most honey, and the lightest because they would die in winter anyhow.

The first sections were somewhat crude. They were in four pieces, and the top piece had in it a saw-kerf to receive the foundation. This top piece was partly split apart, and then brought together again after the insertion of the foundation. I didn't make very good work of it, and wanted to learn how to do it better. I wrote to A. I. Root, telling him exactly how I put in the foundation, making a sketch of it, and asking him how I should do it. I think I had no intention of having my letter published—only to have the proper instruction given in *GLEANINGS*, a publication that I think at that time was gotten out by the aid of a windmill. Promptly came back a round sum in payment for the letter, which was published in full; but not a word was given as to how the work should be better done!

I well remember my first visit to Medina. I reached it by stage, there being no railroad then. Wouldn't a stage coach have a busy time of it now, carrying out all the stuff shipped away by The A. I. Root Co.! On that visit I had the honor of showing A. I. Root an improved method of smoking bees. Yes, you might hardly believe that the man who has sent out so many smokers would learn from me any thing in that line, but he did. I don't remember what plan he was then using. I don't think that, at that time, he smoked them with tobacco as some others did, but the plan I showed him was to have ashes and burning coals in an old tin pan. He was much pleased with the improvement, and I had hardly left the town when he put it in practice, with the result that he jeopardized if he did not burn up a colony by setting fire to the sawdust that surrounded the hive.

A little later I tried to improve on this. I had a close-fitting cover on a kettle containing burning coals and brands, and attached to the cover were two small rubber tubes. I blew into one of them, and with the other directed the smoke upon the bees. It smoked them all right, only it didn't hold fire well unless I "blowed" all the time.

My! my! my! what changes there have been. What improvements! Will there be any more, I wonder? A few years ago a prominent writer said we were not to ex-

pect any more improvements in beekeeping. And yet improvements have been appearing right along ever since then. But I don't see any chance for further improvements—do you? Yet how many of us thought before they appeared that there was any need of sections, foundation, etc.? I don't know what they'll be; but I'm looking for just as great advance in the next 50 years as there has been in the past 50; and it may be that in 1963 some one will be writing reminiscences of "the many great advances in beekeeping since 1913." Who knows?

Marengo, Ill.

WINTER FEEDING; SOFT SUGAR VS. CANDY

An Open Letter to the Editor

BY ARTHUR C. MILLER

• In an editorial (Jan. 1, p. 3) concerning the supplying of extra stores in mid-winter to make up for any possible shortage caused by the mild weather of the fall and early winter, you quote me thus: "Mr. A. C. Miller recently made the statement that coffee A sugar (a moist sugar) can be given to the bees direct;" then you say you "have never tried it," and at once proceed to tell how to use it. Phew! Wait a minute till I whistle, or I may say something hot like ginger and suggestive of brimstone.

In some climates and conditions the bees *may* get by when provided as you direct, but in others, not, nit!

Now I, A. C. Miller, never *recommended* the A sugar for *winter*. You do not say specifically that I did; but taken with the rest of the editorial, that is the natural and unavoidable implication. If, perchance, some poor chump thinks a thing must be good because I said it (or was supposed to have said it), and goes and does something just near enough to what I did say to be *entirely different*, and the results are a bee funeral, there will be something unpleasant coming my way. Excuse my dodging.

Now, here is what I actually said concerning soft sugar for winter use: "Colonies have been wintered on it without any thing else, and that was in southern New Hampshire; but I want to know more about its use thus before I advocate it for such purpose." (Dec. 1, 1912, p. 771.) I have a sort of hazy idea that that assembly of words pretty distinctly conveys the information that I do *not* yet advocate the use of soft sugar for winter.

Let me quote again: "The soft A sugar put in a division-board feeder and hung in beside the brood-nest will serve to keep up brood-rearing as well as the most painstaking

feeding with syrup," etc. (Dec. 1, 1912, p. 771). That does *not* exactly suggest *winter* feeding—at least it doesn't to me.

In your suggestion as to how you think the soft sugar may be used for winter, you would have it put in a dish on top of the frames with sticks across the dish to give the bees access to it under the cushion. Just stop and consider what you have suggested. Little Mr. Innocent, not wanting a lot of paper pie-dishes, goes and uses a soup-plate from the pantry shelf. The bees find a nice cold stone over their heads, and not the remotest suggestion that there is food on top of it, and they starve. Remember, you are suggesting putting that Dutch ceiling over their bedroom in mid winter.

Well, to keep you from feeling too much remorse, I will grant that, between some warm spells, a thick cushion and a lot of bees, the latter do find their way up to the sugar. Bully! But old Boreas kicks up a muss, and the bottom drops out of the thermometer and stays out for a week. Well, why waste words on what happens? It is just as well if you and I do not know what that fellow says about us.

Before we go further, I wish to do a little defining so that, if possible, I can not be misunderstood.

There are several sorts of feeding, one for brood stimulation, one for stores given in mild weather, and one for emergencies given when, for any reason, it is not feasible to expose or seriously disturb the colony. Those "any reasons" may have to do with our personal convenience, as lack of time, dislike of cold fingers or wet feet, laziness, or plain every-day consideration of dollars and cents, as represented in time and material.

At this particular time we are considering the emergencies of colonies starving in cold weather, and we want to prevent that starvation; and if we are worth our keep we want to do it in the most effective and the most economical way.

So far as at present known, a slab of candy placed over the frames meets the conditions better than any other method. It is an old idea and a good practical one. But the making of the candy is a stumblingblock to many. Some will not take the trouble to make it right, others seem unable to do so; and still others, after one attempt, give it up in disgust, and try syrup or let the bees "go hang."

There are candies and candies, and some are good and some are only near good. Your hard candy is all right, but many persons will make a failure of it. The candy made after the Fuller formula (Sept.

1, 1912, p. 545) is easier to get just right. (Pure glucose for the purpose can be obtained from most candy-makers.) This candy has the advantage of *staying right* until consumed.

Common "fondant," as made by the candy-manufacturers, is excellent; but unless it is *just right* it will not stay right, but will soften when subjected to the conditions of the hive and run down between the combs. The property of "rightness" in fondant seems to be dependent on the proportion of tartaric acid to sugar and the time they are boiled together. Some candy-makers can make a firm non-softening fondant every time, while others can not.

On orders for one hundred pounds or over, most candy-makers will make up candy after any desired formula, and will cut it into blocks or slabs of any desired size, and at a cost not so very much above the cost of the sugar. Not a few beekeepers have the professional candy-men make their bee candy for them, considering it better and cheaper than making it at home.

Another word about soft sugar and I am done—no, not out of sputter, but just holding up for a future time.

The use of soft sugar for *stimulative feeding* was, so far as I can learn, first given to the beekeepers by Samuel Simmins, of England, and he should be given the credit for it. I have done so in previous articles, but did not in those quoted. It has been used in this country for many years, but does not seem to have become as widely known as its merits deserve. Now, if your editorial does not put a damper on its use by getting some people in wrong on it—and *they* will surely speak right out loud—its use may spread.

There, I feel better. As I bear no ill feelings, I trust that you will soon be able to sit up and take a little nourishment. As an *emergency* diet, I would suggest *candy*.
Providence, R. I., Jan. 9, 1912.

[Regarding the question of soft sugar for winter feed, we plead guilty that Mr. Miller did not recommend it for cold weather; but we see no reason in the world why it could not be used at such a time if it could be used in warm weather. While it is true that bees can get water during hot weather when they could not during winter, yet as a rule enough moisture collects in the hive to give the bees all the water they need. If the soft sugar is placed in paper pie-plates, the same being placed right above the cluster, as we recommended it, the moisture from the bees ascending will, in all probability, soften it enough more so that it will be excellent winter food.]

If we were guilty of misquoting, we are glad of it now, because it has drawn out a valuable article that will be a stimulus to further discussion of a very important matter—what to feed bees during mid winter when no combs of stores are available. In this connection, if Mr. Miller did not recommend feeding soft sugar during mid winter, there are others who did; but just who, we can not now recall. Very often, by reading a journal for a year one will gather a composite opinion; and that is precisely what we did when we misquoted our friend Miller.

Regarding "fondant" and any sugar using glucose, we have a fear that they will not be all that is desired. We should be more afraid of the use of fondant and candy with glucose in—much more so—than we would of soft cane sugar placed in the paper pie-plates above the bees.

Later.—We sent the above footnote to Mr. Miller, and he has made a further reply which follows.—Ed.]

MORE SUGAR.

That paper pie-plate seems to bother the editor. It is like a cork on a fishline, bound to bob up; but just wait until the condensed moisture he is banking on for the sugar gets in its fine work on that pie-plate, and he will have a first-class paper-pulp "flap-jack." Well, never mind; it is quite likely to be forty-leven miles from the would-be user, and he will try a wash-boiler or an ash-sifter or some other convenient thing.

Now, I hope that I am a brave man, or, what is perhaps as good, am believed to be, for I see danger in what I am about to do. I am going to tell just how the New Hampshire man used the soft sugar when he wintered the two colonies on it. The danger lies in my being given the credit of it and of recommending it, when, as a matter of fact, I am only reporting it.

In the first place, the man who did it was Mr. A. A. Byard, of West Chesterfield, N. H. In the second place, he prepared his bees in the fall, late in the fall, but still the bees could be handled. And he did it thus:

Three empty combs were hung in the middle of each of two chaff-packed hives. On each side of and close up to them were hung division-board feeders solid full of soft sugar. The spaces back of the feeders were stuffed full of dry leaves.

The bees were then shaken into these prepared hives. Now, I do *not* know whether he shook them in on top of the frames and feeders or down in front of the entrance and let them waltz in; but he got them into those hives and on to and between the combs—leastwise *most* of them—for he

so planned space to bees that when the latter had crowded in as tight as if Mrs. Mulligan's goat had butted them in, some of them still stuck out at the entrance. See the point? Well, it is this: The *whole space was full of bees*. That is *not* the way they are on combs of honey in a brood-chamber under normal conditions. No.

Over the combs, feeders, and bees he had a sheet of oilcloth (enameled cloth), slippery side down, and on top of that more leaves—lots more, nice dry maple leaves. (Packing is not my long suit, so you can tell that it is some other fellow's circus that I am talking about.)

Then he said "go it;" and he went, and the bees stayed; and in the spring the two colonies were as fine as any he had, and he had some fine ones.

Certainly he had to give more combs in the spring; but that is not part of this story.

Now, Byard is the man who did it. And I'll whisper another thing, though he may shake half the life out of me when he finds it out. (Oh, yes! he can, for he is almost seven feet long, and I am not.) It is this: Byard is a wizard—yes, sir, a sure-nuf wizard. I wish you could see him put foundation in sections—make you cry with envy. What has that got to do with soft sugar? I was only going to the foundation of the thing.

Don't worry, dear editor, don't worry, I mean about fondant and bee candy with glucose in it. A whole lot of beekeepers in little old New England have used it successfully for several seasons. It is a hard condition which confronts you, not a theory.

Providence, R. I., Jan. 15.

THE DESTRUCTIVE FREEZE IN CALIFORNIA

BY P. C. CHADWICK

Listen to this short story; preserve this issue for reference ten or twenty years from now. Jan. 1, 2, and 3, 1913, were as fair, bright, warm winter days as California may ever expect to see. On the fourth, the winter morning chill did not yield to the sun as usual. A cool wind began to shift from one direction to another, only to settle itself in the north. Near the noon hour it was a "nother in earnest." Dust became blinding; leaves were whipped from the trees; telephone wires were crossed and crisscrossed. Fruit-growers began to look

anxious; for the grave danger, *frost*, is always feared by them. All day and all night it continued; but instead of holding the temperature above danger, as expected, it went steadily down, in the face of the wind. All day Sunday, the 5th, it blew a gale; the highest point reached in temperature was 40 at noon. Monday morning, Jan. 6, gave us a temperature of 18, with a howling northern gale still in progress.

Many fruit-growers threw up their hands in despair. Many had smudged all night while the frost was penetrating the fruit a few feet from their smudge-pots.

By mid-afternoon another danger was approaching—the trees! the trees! back to the smudge-pots! save the trees! Tuesday morning, the 7th, great clouds of dense black smoke were hanging in the silent air. Auto load after auto load of smoke-begrimed men were arriving from the all-night fight with Jack Frost, to save the trees, dressed in gloves and overcoats, with heads wrapped tightly, and the wearers half frozen by the stinging cold.

Almost by accident I went into a plumbing shop where the plumber had just opened up for the day's business; but his telephone was ringing, "Water-pipe burst." Busier plumbers were never seen. Water-pipes burst by the score; closet-tanks were frozen; a fire-hydrant burst; ice in the gutters—everywhere ice, ice, ice; and all of this in Redlands, Cal., and the same tale may be told in any of our southland cities of the great so-called frostless belt. No man had ever seen such before, and we pray that none may ever see it again. The \$50,000,000 citrus crop of southern California is "gone up in smoke." People fail to realize the extent of the disaster.

But how about the beemen? I do not know. One thing is quite sure—every pollen-producing flower has been destroyed. The eucalyptus bloom is largely if not completely destroyed. All of our southland districts have suffered alike. All must wait for a new source to develop from which the little bee can gather an impetus for renewed hope sufficient to cause them to continue breeding operations. Orange bloom is doubtful as to the quantity the trees will be able to put out. Many trees are badly injured. As to the sage, we do not know. Hope is entertained that, if we should get sufficient rain, it will bloom profusely; but it may be the bloom is injured deep in the stem from the excessive freeze. No such freeze has ever been experienced in the recollection of the oldest inhabitants, so we must wait patiently our future.

Redlands, Cal.

This is not an iceberg, but an orange-tree in Redlands, Cal., on which the spray from a garden hose was left running during the night of Jan. 6, 1913. The picture was taken about 10 A.M., Jan. 7, and gives an idea of the intense cold in southern California on the above date. Photographed by E. T. Everett, of Redlands—to be copyrighted. Permission to print granted GLEANINGS IN BEE CULTURE.—P. C. CHADWICK.

EXPERIENCES OF A FOUL-BROOD INSPECTOR

The Value of Vigorous Italians in a Diseased Locality

BY J. E. CRANE

Continued from page 58, Jan. 15.

One gentleman, whose reputation as an intelligent beekeeper was known to me, invited me to visit him, and I anticipated a treat. Almost all his bees were Italians, and he told me he had no fear of foul brood. I was rather surprised, because I had seen its deadly work in other places. But he stated that at one time he bought a lot of bees and transferred them into his hives and put the odds and ends of wax and honey out in the open for his bees to clean up, after which he learned that the colonies he had bought had foul brood. Almost every one of his black colonies was ruined, while his Italian stock remained uninjured. This made him wise, and he has since kept his stock well bred with Italian queens, and he has had little trouble with foul brood.

Last winter he went over to a town some miles away and bought eight or ten hives of black bees that were represented as being free from disease. But when spring came, European foul brood developed. "Now look at that one," said he. I looked, and found the bees black and in an advanced stage of foul brood. "Now look at this one," said he. "It was bad in the spring, but I put in an Italian queen." I looked very carefully, but not a trace of disease could I find. This beekeeper had no use for

"goldens," but wanted dark or leather-colored Italians. The fact that he has kept up his stock and had 160 colonies in one yard, while his neighbors that stuck to black bees had nearly all gone out of business, would indicate that there is much in his views and method of combating and curing foul brood.

I found another very progressive beekeeper trying to cure disease by using golden Italians; but I believe that where colonies were very bad, he destroyed the old combs. He has been fighting it for years, and feels that, with the assistance of Italian strains of bees, he has succeeded very well. The last time I saw him he thought his bees were entirely free from it, while most of the black bees in hundreds of colonies in his neighborhood are dead as a result of the ravages of foul brood. He told me one thing of great interest. He said that he had never been able to rear a queen in a foul-broody hive that proved to be of any value in combating the disease, and that to cure a colony the queen must be reared in a hive of healthy bees. It sounds reasonable.

I met another extensive beekeeper who was preparing to rear queens. He had about 200 colonies in one yard. He had had some trouble with foul brood, but thought he had it all cleaned out; but just as I was leaving I opened a colony of most beautiful golden Italians, and, much to his surprise, showed him some diseased brood. "There it is again. I supposed that, the yellower the bees were, the better they would resist disease," said he. I gave him

my opinion that the ability of bees to resist disease depended more on their strength and vigor of constitution than the color of their abdominal rings.

On the whole it now looks as though the introduction of vigorous strains of Italian bees might, in skillful hands, prove a short cut in curing European foul brood.

NEW STYLE OF BEE-ESCAPE.

Speaking of short cuts reminds me of a new style of bee-escape one beekeeper showed me, for which credit should be given to A. W. Darby, of Alburgh, Vt. It was simply a frame of one-inch lumber the size of the brood-chamber, with thin lumber one-fourth or three-eighths of an inch thick nailed to one side with a three-eighths hole bored in one end, into which was inserted a little tube of wire cloth about three inches long, and the diameter of a lead-pencil. It was used as a honey-board without the tube usually; but when wanted as an escape-board it was placed under the super, and the tube inserted. It then makes the best kind of escape, and costs much less than the Porter. We have tested it, and know it works very satisfactorily. The same answers for a honey-board, and the originator uses it for feeding and also for ventilating; for, with a hole through the bottom of this board, the bees in hot weather draw the air down through it and out at the entrance. When closed with a cover, or when a quilt is placed in it in early spring, it helps to retain the heat; and during very hot weather it is a shelter from the heat of the sun. The returning bees try to get into the super at the base of the wire-cloth tube, but not at the end. We have tested it, and it works perfectly.

GREAT DIFFERENCE IN TEMPER OF BEES.

I have found a great difference in the temper of bees in different yards. Some

are gentle, and very easily handled, while others are so cross that it is hard to find words to describe them. So far I have not

been able to account for the difference. I have sometimes thought some beekeepers were not altogether averse to seeing the inspector stung a little, as they seemed quite amused at his misfortune.

SOME ATTRACTIVE APIARIES.

One very intelligent beekeeper had two or three sheep in his bee-yard all summer. They kept it looking like a lawn, and it seemed to me the best plan I have ever known for keeping down the grass, as the sheep were never in the way. Another beekeeper, Mr. W. A. Grover, of New Haven, Vt., had an exceedingly attractive yard and honey-house. His apiary numbers 100 colonies; and, besides, he has a large farm;

keeps about 15 cows and 600 hens. I inquired how many dozen eggs his 600 hens produced. He said he did not know, but he had sold \$1300 worth of eggs in a year, and it cost him about one half for feed for them.

He hives his early swarms on old combs that he has wintered over; and after a colony has been queenless for seven or eight days, or long enough so that the brood is

Grass "mown" by sheep pastured in the yard.

FIRST ANNUAL CONVENTION OF IOWA BEEKEEPERS' ASSOCIATION.

Top row, from left to right: G. W. Fehleisen, B. A. Aldrich, J. S. Myers, A. D. Clancy, J. C. Donahue, M. E. Tapp, B. H. Tripp. First row from top: G. W. Nance, J. P. Blunk, L. M. Carlson, W. S. Pangburn, J. W. Stine, J. B. Espy, W. H. Winch, J. H. Schweer. Second row from top: J. C. Stocks, Arthur Wright, W. H. Pearson, E. E. Towns, Mrs. E. C. Wheeler, Miss Nina Secor, E. E. Townsend, R. R. Grantham, J. H. Burghdoff. Third row from top: A. F. Bonney, E. C. Wheeler, Eugene Secor, S. W. Snyder, Frank C. Pellett, J. L. Strong, M. G. Dada, J. A. L. Fourth row from top: Hamlin B. Miller, J. W. Schlenker, F. C. Scranton.

all sealed, he puts a new swarm on these combs. Of course the queen-cells are destroyed. He says they rarely or never swarm; and as brood is constantly hatching, the new swarm is maintained at sufficient strength to store an abundance of surplus if any is to be had.

Middlebury, Vt.

REPORT OF MEETING OF IOWA BEEKEEPERS' ASSOCIATION

BY F. C. SCRANTON

The Iowa Beekeepers' Association held its first annual session at Des Moines, Dec. 12 and 13. Both the attendance and the interest shown were very encouraging. Beekeepers from all parts of the State attended, and gave their experiences on the production and sale of honey. It was pleasing

to note the determination of all present to raise the honey standards as high as possible, and to clean up foul brood effectively.

Prof. W. J. Kennedy, of the Extension Department of the State Agricultural College at Ames, and Prof. H. E. Summers, State Entomologist, both addressed the meeting, and were heartily in favor of the college extending all possible assistance to the beekeepers of the State. Both of these gentlemen approved of the establishment of an apicultural department at Ames. Prof. Kennedy has placed Mr. C. H. True, of Edgewood, on the extension department in charge of apiculture for this season. Prof. Summers very generously proffered the service of his department in the inspection work. His men are continually covering the State inspecting plants and trees, and could very economically handle the bee inspection at the same time.

A constitution for the association was adopted, and the usual routine work of passing resolutions, appointing committees, etc., was carried out.

It was decided to ask that the State Entomologist be given an assistant in apiculture; that the State legislature provide sufficient appropriation to inspect apiaries and treat diseased colonies thoroughly; that to insure against spreading foul brood our present law should be amended to prohibit shipment of bees from outside the State or from one county to another without a certificate of health signed by some duly authorized Government or State inspector.

The following officers were elected for the ensuing year:

President, Frank C. Pellett, Atlantic, Ia.
Vice-president, J. W. Stine, Salem, Ia.
Secretary, S. W. Snyder, Center Point, Iowa.

Treasurer, C. H. True, Edgewood, Ia.

Directors: Dr. A. F. Bonney, Buck Grove, Ia.; Hamlin B. Miller, Marshalltown, Ia.; E. C. Wheeler, Marshalltown, Ia.

The next annual convention will be held at Des Moines.

A FURTHER NOTE ON THE SUPPOSED DISLIKE OF BEES FOR BLACK

BY JOHN H. LOVELL

It has been stated that a black object moving about in the apiary is more readily seen by the bees than a white one; conversely, in the darkness of night a white object is the more conspicuous. Moth-flowers blooming in the evening are usually white; blue or red petals would be almost invisible. In this connection it is not without interest to note that ghosts are always

FIG. 1.—F. A. Powers' telescopic covers with cushions nailed to inner covers, showing also the concrete hive-stands.

described as white—a black ghost would be an anomaly. Since white contrasts so strongly with black, it follows of necessity that, in the white light of a summer's day, a black object is more conspicuous than a white one.

A bright-red object excites anger or annoyance when inanimate as much as when endowed with life. When the wearer of a bright-red cloak in crossing a pasture is chased by a bull, if the cloak is thrown upon the ground, the angry animal attacks it, giving the wearer a chance to escape. Children may be rendered nervous and irritable, not only when dressed in bright-red clothing, but also by sitting much of the time in rooms with walls painted a glaring red. But if a black shawl be thrown upon the ground near a hive, or be spread over a bush, the bees pay no attention to it—at least they do not attempt to sting it. But a black animal moving about among the hives excites fear, and receives more stings than it would if white, because it is more conspicuous. But a beekeeper dressed in immaculate white, if he disturbs a hive of cross bees, will undoubtedly be attacked.

In the case related by Dr. Miller, where a small number of bees followed the black head of a hat-pin half a day, it seems not improbable that the smooth shining black ball exercised an attraction comparable to that of an electric bulb for many insects at dark. Naturally bees experience an antipathy to any one working in the apiary, and are inclined to follow him from place to place. The shining black head of the hat-pin would attract their attention

more than any other point on the person of the apiarist; and they would, therefore, be likely to direct their efforts against it more than to any other spot.

Waldoboro, Maine.

CONCRETE HIVE-STANDS

BY E. F. ATWATER

Among the beekeepers of South Idaho and East Oregon there are probably none who are deeper thinkers or more thorough beekeepers than Mr. F. A. Powers, of Parma, Idaho. Large in person, and with that cheerful disposition which makes him laugh when confronted with difficulties, one may well expect him to be a beekeeper of originality and enterprise.

Located on the fertile bench land at the east of Parma, with an abundance of alfalfa near by, with an orchard windbreak, his apiary of 250 colonies is very favorably situated. As Mr. Powers is a specialist in the production of fancy comb honey his hives and appliances are built with that end in view. His hive is virtually a standard ten-frame hive in which he uses nine staple-spaced frames and a heavy dummy. Owing to the cool nights prevalent in Idaho, and with a desire to maintain a favorable temperature in comb-honey supers, as well as to afford sufficient protection for wintering in the mild climate of the Boise Valley, Mr. Powers uses a telescoping lid perhaps 4 inches deep, with a cushion over an inner cover. The cover proper consists of a simple rim with tin or galvanized iron over the

top. The cushion much resembles a mattress about two inches thick, which holds its shape, and is nailed to the under side of the inner cover. While some beekeepers use a cushion above an inner cover, Mr. Powers is, so far as I know, the first to invert the arrangement, using the inner cover above the cushion. By having the cushion firmly attached to the inner cover it maintains its shape, and there is one less loose piece to handle. This arrangement, as shown in Fig. 1, is used on the hives the year round, with the best results, and certainly no other apiary which the writer has examined in early spring has shown the average strength of Mr. Powers' colonies in April, 1912.

Not being satisfied with the usual make-shift hive-stands, Mr. Powers has devised and now uses the concrete stands shown in figures 1 and 2. The method of making these stands is simplicity itself. Forms perhaps two inches deep, shaped as shown, and resting directly on the bare ground, are filled with concrete, and left to harden for some time.

EXPERIMENTS WITH DIFFERENT RACES.

Mr. Powers has experimented on quite a large scale to find the best strain of bees for the production of comb honey in his locality. Starting with an excellent strain of Italians, the first experiment was the introduction of Carniolan breeding queens, from which the entire yard was requeened. If I am not mistaken, from the resultant Carnio-Italian cross Mr. Powers secured the largest average per colony which he has ever taken.

About this time the rise of Banat bees occurred in our beekeeping periodicals. Imported queens of this race were secured and tested. It was found that the new bees, while perhaps not so prolific as the Carniolans, produced fully

as much fancy honey, perhaps even exceeding the Carniolans in whiteness of capping, in using the minimum of propolis and in gentleness.

The yard was then requeened with daughters of the Banat breeders, most of them mating with Italian drones. But after trying the Banats and their crosses for some years Mr. Powers has come to think less highly of them than before. Their universal fault, in this locality, is their diminution in strength and working energy during the blossoming of the second crop of alfalfa—the very time when we need colonies with a maximum of strength.

Meridian, Idaho.

[Nearly all the reports have indicated that the Banats are less desirable than Italians or Carniolans. It looks as though they, like the Punic, deserve to be forgotten.—Ed.]

INVENTIONS AND IMPROVEMENTS THAT HAVE TAKEN PLACE DURING THE LAST FORTY YEARS

BY E. R. ROOT

To record the history of the inventions or improvements, rather, during the last forty years means that I must go back at least twenty years further; for sixty years has really seen all the important developments that have made bee culture what it is to-day.

There are three inventions that revolutionized the methods of work with bees, and which really form the basis of all modern methods of management to-day. First and foremost is the invention of movable frames by Father Langstroth in 1851. No one to-day, either in Europe or this country, I believe, questions Mr. Langstroth's right to the honor of this great invention, for practically all hives and frames in use to-day are Langstroth's.

Next followed the invention of comb foundation by J. Mehring, in 1857. But the foundation he made had no side walls, and so it remained for Samuel Wagner, twenty years later, to develop the product that we now use with side walls.

The next great invention was that of the honey-extractor, by Major Francisco Hruschka, in 1865. There have been a large number of improvements that have made the inventions of Langstroth, Mehring, and Hruschka much more workable than they were originally; however, it is but fair to say that Langstroth came very near making his hive and frame almost perfect at the very start; and there are possibly thousands

of our readers who would consider the later improvements made in the Langstroth frame and hive of doubtful value. It is, nevertheless, a fact that the old movable frame, as first made by Mr. Langstroth, both as regards the dimensions and style, is still in use all over the world. For extracting purposes, some of our large honey-producers will have no other. They regard any thing in the way of a self-spacing attachment, either as part of the hive or frame, as unnecessary, and a backward step. But we will not stop to argue that question now.

The original comb foundation by Mehring was a very crude product; and it may be questioned whether or not Wagner should not share equal honor in the invention. The great improvements that were made in this article had more to do with the machinery for making the product than the thing itself. It may be egotistical for me to say it, but I believe my father, A. I. Root, did more to perfect comb foundation than perhaps any other man, unless it was his co-laborer and mechanic, Mr. Alva Washburn. He certainly introduced it to the beekeeping public. The first foundation was turned out on plates, and was, therefore, a very crude article, but A. I. Root (for I well remember his early experiments) conceived the idea of having it made by means of a pair of rolls. This suggestion came to him when noticing the wet clothes as they came out from a common wringer in his own home. After consulting this friend and mechanic, Mr. Washburn, a pair of rolls were made, the product of which was fully the equal of any comb foundation made on the modern machines of to-day. To Mr. Washburn be-

longs the credit of making perfect comb foundation on rolls that were mechanically correct. The only improvement made on the Washburn mills was in the *method* of making them, by which they could be turned out for one-fifth the cost, thus enabling every beekeeper to own a comb-foundation machine if he desired. Later improvements were made by E. B. Weed, which will be referred to later.

As regards the invention of Hruschka, several machines were made and put on the market. The one made by J. L. Peabody consisted of a can that revolved without gearing. The limitations of this were such that very few of them were ever sold. To A. I. Root (if you will pardon me again) belongs the credit of making some of the first all-metal extractors that used gearing, a stationary can with baskets, or containers, for holding the combs, so constructed that they could revolve inside of the can. Thousands and thousands of these machines were sold, and very little in the way of improvement was made until the reversible extractor was put on the market. The Cowan principle was applied to the two-frame machines, and later came the Root principle of a series of baskets geared together in such a way that the reversing of one pocket reversed all at the same time. Later came the invention of Mr. Frank G. Marbach, by means of which the pockets could be reversed *automatically* by simply applying a brake and slowing down the speed of the machine. This was followed by a slip gear and better mechanism, by which the extractor of to-day has from two to ten times the capacity of the earlier machines. In this connection we must not omit to mention the honey-pump that is now being used successfully on the large-sized extractors to deliver the honey from the extractor to a tank above or anywhere else.

There is one more important invention that, perhaps, ought to be classed with the movable frame, comb foundation, and the extractor; and that is the bee-smoker. Moses Quinby was the inventor of the bellows bee-smoker, which he brought out in 1875. This was further improved by T. F. Bingham, L. C. Root, and H. H. Root, younger son of A. I. Root. The modern bee-smoker is almost as indispensable as an extractor and movable frames; for without smoke, applied by means of a convenient instrument, the work of handling bees would be awfully disagreeable if not impossible at times. The invention of father Quinby forms the basis of all the modern smokers of to-day. But to T. F. Bingham belongs the credit of

devising a smoker that blows air into the fire-cup without sucking any smoke into the bellows. Mr. Bingham's invention consisted in leaving out the tube connecting the two parts of the instrument. While that at first thought might seem to be no invention, yet it made all the difference in the world between a workable tool and an unworkable one. The latter would go out and fill up with creosote, while the former would stay lit, burn any kind of fuel, and not clog up.

E. B. Weed, formerly of Medina, was the inventor of what is known as the "Weed New Process" for making comb foundation of a very superior kind in large quantities. His automatic machinery, with Washburn's and Howk's improvements for turning out the product, is now used in nearly all civilized countries of the world. This invention almost ought to be classed among the four great inventions—the movable frame, comb foundation, the extractor, and the bee-smoker.

An invention which is now in almost universal use, in this country at least, is that of the late Julius Hoffman, in what is known as the Hoffman self-spacing frame. While the old-style Langstroth non-spacing frame is one that is generally sold, the Hoffman-Langstroth is one that is listed by large and small manufacturers and dealers all over the country. It is an invention that has come to stay. I should say, however, that the present Hoffman frame is not the same as the original Hoffman; or, to put it in another way, the modern Hoffman retains only the self-spacing end-bars of the original, and not the Hoffman top-bar.

Another improvement was suggested by Mr. Francis Danzenbaker; namely, the lock cornering on hives. This feature has now come to be adopted by all modern hive-makers throughout the United States, and, to a great extent, throughout the world. Mr. Danzenbaker was also the inventor of a reversible closed-end frame that is being used by a large number of comb-honey producers.

The invention of the sectional honey-box is not attributable to any one person; however, A. I. Root was the first man to make one holding one pound. His first pound sections were dovetailed all around. Later on came the invention of the one-piece section, on which J. H. Fornerook secured a patent; but after long litigation from one court to another, the Supreme Court finally declared it "null and void for want of novelty." It was shown that one J. Fiddes and a number of others had made and used sections of this kind; so in the matter of one-

piece sections we shall have to divide the honor among four or five different people. Mr. James G. Gray, still of Medina, made the first practical machine for making one-piece sections. Later, machines for turning out section honey-boxes in lots of one hundred thousand a day were the invention of our Mr. George L. Howk.

The Porter bee-escape is one of the best little inventions that have been brought out. It is one of the few patented inventions that survived. It is used very largely by comb-honey producers.

Queen-excluders in the form of perforated zinc and spaced wires are inventions of merit. In connection with these we find entrance-guards and Alley traps that are useful. The Alley trap is another patented invention that survived.

The new steam uncapping-knife is an invention that is coming more and more into use. The Peterson capping-melter for melting cappings as fast as they come from the knife gives promise of being one of the inventions that will last; for it enables a competent man who follows directions to melt his cappings and separate the honey from the cappings immediately; so that when the day's work is done he will have his honey separated from the cappings, and the cappings made into wax ready for use.

Mr. Arthur C. Miller was the discoverer or the inventor of the principle that is now used in all modern foundation-fasteners using a hot plate; yet, strangely enough, not one of these fasteners bears his name. Mr. Miller was also the inventor of two or three different uncapping-machines, and of a steam-heated uncapping-knife. If he had applied for letters-patent on this kind of knife it would have been granted him, and he would be to-day considered the inventor, as he really is, of the steam-heated uncapping-knife.

An invention that gives promise is the Ferguson uncapping-machine. It has been tried in an experimental way, and some of its friends believe it will save a large amount of time over the old way with an uncapping-knife.

Mr. T. F. Bingham and Mr. Hetherington were really the inventors of the modern uncapping-knife popularly known as the Bingham. The Bingham-Hetherington principle is now used in all uncapping-knives, whether steam-heated or plain.

No one seems to have invented the double-walled packed hive for outdoor wintering; but A. I. Root was, perhaps, in connection with Mr. J. H. Townley, the first to apply the principle of chaff packing in double walls. As chaff is not now obtain-

able, other packing material is being used. Langstroth in the early 50's used double hives but not packed.

In the early 80's there were a hoard of inventions relating to feeders, foundation-fasteners, and reversing attachments for movable frames, nearly all of which died a natural death because they were impracticable and only increased the cost of management. When a good brother has been carried away with the invention of a feeder, foundation-fastener, or a scheme for wiring frames, or reversing frames, we almost feel sorry for him—almost as much so as for the man who has invented a new hive which *he thoroughly believes* is going to revolutionize all methods of management. While I do not class all inventors of feeders, fasteners, and hives as belonging to the crowd of ignoramuses, I am compelled to believe that most inventions relating to modern bee culture are not worth the paper that it takes to illustrate and describe them. This seems pretty hard on the average apicultural inventor; but if one will look through the Patent Office and inspect the list of 2000 and more of hive patents and bee-appliances, and then remember that only three, or four of these have survived, he will see that my statement is not far from correct.

Among the later hive inventions that have merit is the Aspinwall hive, based on the principle designed to prevent swarming. Whether this will ever come into general use remains to be seen; but its cost of construction, and the large number of extra parts that must be manipulated at intervals, will probably prevent this hive from displacing the standard hives in use to any great extent. The swarming problem is not a serious one in the production of extracted honey; and while probably three-fourths if not four-fifths of all the honey produced in the world is extracted, it will be seen that there will be a very limited demand at best for non-swarming hives.

In the way of minor inventions or improvements, rather, I may mention the omission of porticos on hives; and of bevel edges between the parts of the hives. A hive plain and simple, with a detachable bottom-board and a plain simple cover, is much more workable than some of the complicated affairs of the early days with moth-traps, porticos, etc. It is another improvement to have the hive body and supers of the same dimensions and the same depth, except in the case of half-depth supers, which are really multiples of the full-depth. In a word, the modern improved hive is made up of multiples of parts that will fit

each other in any combination, permitting of any degree of expansion and contraction to accommodate a large or small colony. This feature of interchangeability is prized almost as much as any one single invention, barring only the three great inventions first mentioned.

It might be interesting and perhaps enlightening to some would-be inventors to record here a list of the inventions that have died a natural death for want of patronage. Some of these at the time were widely heralded as revolutionary; but they never "revolutionized," but, on the contrary, sickened and died, as thousands of others had done. It is well that they did.

Perhaps at some future time, when we have more space, it may be interesting and profitable to give a list of these inventions, and explain when, where, and *why* they died.

BEE NOTES FROM CONTINENTAL EUROPE

Sending Honey and Bees by Parcel Post; Carried on in a Large Way in Most Countries of the European Continent

BY R. LINDE

If in matters apicultural some beekeepers over the sea are far ahead of those in the Old World, we have on this side of the ocean some institutions that seem to be far better developed than the same institutions in Uncle Sam's country. I have mainly in view our parcel-post system, the very importance of which, from a purely business standpoint, has long received the very closest consideration of the postal authorities in most of the larger states of continental Europe.

In almost every town, whether large or small, there are markets held once or twice a week for fruit-growers, kitchen gardeners, and farmers. The beekeeper, if he desires to sell his products directly to the consumer, and does not like peddling his honey, must resort to parcel post, and now we could not do without it any more than we could without the letter post.

There is a close similarity between the postal regulations and postal tariffs of most of the larger European states; so it will be sufficient if I give some data of our German postal institutions so far as parcel post is concerned.

It is really astonishing to note what a very large amount of business is carried on solely through parcel post in most countries on this continent. Almost every thing is sent into one's home by it. The post

cashs the bill when delivering the parcel. In nearly every large daily paper you find small advertisements offering to send honey in any quantity direct from the apiary. In most European countries, where protection prevails, food adulteration is carried on extensively, mostly in a refined sense or in a veiled way. Consumers have become very suspicious, and always prefer to buy from the beekeeper direct if they can get in touch with him. Now, that is really possible through parcel post, as the low rates allow even small quantities to be carried without unduly swelling the bill.

If one resides in a locality where little honey is consumed, all he has to do is to advertise in a paper with a wide circulation, in a large town, and he may be sure to get sufficient orders to dispose of all the honey he is likely to produce.

PARCEL-POST CHARGES.

There is a uniform rate for all parcels up to about 11 pounds (5 kilograms). The charge is about 12 cts. for all distances unless the parcel is to be delivered within a radius of about 50 miles, when only half of this amount is charged—namely, 6 cts. If the charge is not prepaid, an additional charge of 2½ cts. is made. Quite apart from this regular charge, a further charge is made for delivering the parcel to your home, which varies somewhat in the different postal districts, and amounts to from 2½ to 3½ cts. In fact, every parcel will be delivered at your home unless you sign a form at the postoffice declaring that you want to take your parcels yourself. In that case no delivery charge is made. This delivery charge, as separated from the general charge, is mostly overlooked—at least not taken into account by the general public when ordering goods offered at a certain price, carriage paid; therefore, while the parcel-post charge is, in many cases, borne by the seller, the delivery charge is always borne by the buyer, tacitly.

If the weight of the parcel exceeds eleven pounds, then an additional charge is made for the overweight in accordance to a zone tariff. For every kilo (2.2 lbs.) the parcel weighs above 11 lbs., an additional charge of 2½ cts. is made if the distance the parcel is to go is below 100 miles; the distance may be up to 250 or 500 miles, in which case this additional charge amounts to 5 and 7½ cts. respectively. The effect of this zone tariff for the overweight above 11 lbs. is to reduce the number of heavy parcels, for the handling of which the post is not especially equipped.

Parcels that exceed a certain measure—for instance, about one yard in length, are

barred from the ordinary rates, and are charged one-half above the ordinary rates. Living animals, as, for instance, bees, are charged the same as barred goods—that is, one-half above the ordinary rates.

This year I got by parcel post all the colonies I bought. A colony of 6 lbs. packed in a box, weighing not more than 5 lbs., would incur a postage of 18 plus 4 cts. delivery charge. In this country it is far cheaper to ship bees by rail, as all our state-owned railways have a special low freight rate for bees, and treat them as express goods. That means that bees are carried on passenger trains or express goods trains. However, the post reaches every small village, whereas the railway does not; so if you don't live close to a railway station it will probably be cheaper to send single lots of bees by parcel post.

For cashing the bill, the post charges 2½ cts. in addition to the postage for the money order that would be required for remitting the amount cashed. The cashing request may be put on a letter, a post card, or a parcel; the charge for presenting this cashing order is always the same, and must be added to the postage of the letter, the post card, or the parcel.

SELLING DIRECT TO CONSUMER BY MEANS OF PARCEL POST.

Let us take an example to make clear what expenses will be incurred from producer to consumer by parcel post. In this country, an eleven-pound parcel of good quality honey in a tin package (containing 10 lbs. of honey) is usually offered at \$2.50 post-paid, package included. The parcel-post charge amounts to 12 cts. (or

only 6 cts. if the distance the parcel is to go is within 50 miles). For presenting the bill, the post charges 2½ cts. The money-order postage for \$2.50 would be 5 cts., and for paying the money to the recipient at his home a further charge of 1 ct. is made. The whole transaction would incur an expense of 20½ cts.—that is, about 8.2 per cent of the amount in question.

HONEY-PACKAGES FOR PARCEL POST.

As a consequence of this ease of selling honey by parcel post, special packages have

Different packages used in Europe for sending honey by parcel post.

been put on the market over here. Illustrations of these packages will, I am sure, be of special interest to you just now.

Figs. 1 to 3 show a cheap tin, very extensively used for candied honey. For liquid honey the lid would not be honey-tight. However, it can easily be made perfectly tight by putting thin parchment paper over the mouth of the tin, then pressing the lid on only lightly, and trimming the paper with a sharp-pointed knife. The inside of the edge of the paper that afterward comes in contact with the tin is covered, by means of a small brush, with a thin layer of a molten mixture of beeswax and resin, after which the lid is pressed down firmly.

This tin is put into a box of corrugated paper, as shown in Fig. 3, and is then ready to be posted as a postal card.

For liquid honey the tin shown in Figs. 4 and 5 is far better adapted, being provided with a lever lid that is perfectly air-tight if pressed down properly. I am myself using the tin shown in Fig. 6, which is both simple and effective. The elastic iron bow pressed over the lid and secured to the body of the tin (on one side by means of a spring, the ends of which ought to be sealed with lead or sealingwax) serves as a carrying handle. I find that this kind of package travels better without any envelop of corrugated paper; because the postmen, seeing the tin, and instantly inferring that it contains a liquid (they hardly ever read the labels) don't dare throw it about, but always take it up by the handle. However, the bottom part of this kind of tin has to be made just a trifle stronger than was necessary with the tin shown in Figs. 1 to 3, and the body ought to be strengthened in the way shown in Fig. 6.

These tins usually carry about 10 lbs. of honey, so there remains a margin of one pound. The weight of the tin is a little over half a pound. The whole package comes close to eleven pounds when filled and labeled. There is some demand for tins taking only 5 to 6 lbs. of honey.

I have often wondered how it is that in English-speaking countries there is no parcel post worth speaking about. But they do not have state-owned railways in English-speaking countries. Perhaps in some way the interests of railway companies are affected by parcel post. Anyhow, the interests of railway companies, however powerful they may be, must not be allowed to stand in the way if the interests of the people demand parcel post. And that parcel post is of great help to the beekeeper, whether large or small, the fraternity on

the other side of the ocean will soon know by experience.

From GLEANINGS for Oct. 15, p. 645, I just learned (while writing this article) that parcel post will be an institution in the United States after January 1. It is true there are greater distances to be taken into account in the United States than in the countries on this continent; still, at the rates outlined above, a parcel may travel right through Germany and Austria-Hungary (between these countries there exists a special postal union), a distance equal to that between Florida and Ohio.

Beekeepers across the sea have my best wishes for the thorough success of their new parcel post, which, I am quite sure, will soon be deprived of its provisional character; because, once you have got it, you will soon see that you can't do without it.

Wendhausen b. Hildesheim, Germany.

REMINISCENCES OF BEEKEEPING 50 YEARS AGO

BY A. F. FOSTER

The happenings of a day shape the destiny of a family. It was a chilly November day in 1860. Father and I went six miles on foot for a cow and calf. The paths were sloppy with snow, and we were soon tired chasing through the brush up hill and down. As a slender lad I found the journey tiresome, and about the middle of the afternoon I wanted my dinner.

We came to a large farmhouse with a big barn, and sheds, orchard, garden, and a few hives. Mr. A., an Englishman with whom father had some business, offered us a lunch of bread and butter, milk, and honey. The women were away, but we were made welcome in a warm kitchen, and helped ourselves from the table with its huge loaf, a large pitcher of milk, a pat of fresh butter, and a bowl of yellow grainy basswood honey. The lad of sixteen had a boy's appetite, and this was his first taste of honey. He began with a sup of milk, a slice of bread, and butter and honey. Then some honey on another piece dipped in the cup of sweet creamy milk; then more bread and honey, and then some with silent reflections, "If pa would keep bees we might have honey on our table." Was it a prayer? Surely it was the "soul's sincere desire," and had a prompt answer, for father just then spoke of buying a hive of Mr. A.; and ere we finished the lunch the bargain was made and a box hive was ours.

Later during the summer of 1862 father joined the army of the boys in blue and

left me for nearly three years in charge of a poorly equipped farm, and with the care of a brave gentle mother, and four children younger than myself. The struggle with poverty was a pathetic one. Our brave mother passed away before our father returned; but during that dark period that colony of bees and one other engaged my attention. They had been placed side by side on a low bench in the garret of our stone house just under the roof. Two small openings one foot square answered for open doors through which the bees came and went in a constant stream. As we had no sections or smokers in those days I set about making some boxes to hold the surplus. From some old half-inch basswood siding boxes were made holding about five pounds each. A round hole about the size of a fist was made, and a scrap of glass tacked on the inside through which we could see when the bees began to work upstairs. A scrap of nice honeycomb in the further end led the bees to begin work there; and as the work came nearer the glass we easily determined when the box was finished. Two boxes upon the smaller hive, and three on the larger one, were changed again and again, until about 125 pounds were secured. This was, to our neighbor's thought, a marvelous crop, and yet I could see that my methods could be greatly improved, for a large cluster of bees had hung out all season, and had built combs enough to contain 50 pounds of honey; but later the combs were empty, the honey having been carried into the hive, which was a large one.

About this time I met Edwin France, of Platteville, at the county fair. I related my experience, and he took great pains to explain the management of movable combs, showing me his hive with bees in perfect working order, and imparting to me some of his enthusiasm. Later I visited his home and returned with a hive and colony on nice straight combs, which made the study of bees easy and fascinating. Some years later my brother, Oliver Foster, and I reared from a golden Italian some fine queens and began scientific bee culture at Mt. Vernon, Iowa.

In 1878, while traveling through Ohio visiting relatives, I called on A. I. Root at Medina. Mr. Root was busy in his shop with clocks and watches, but directed me to the back room where some of his helpers were working wax into foundation. Later in the day I called at his home where a lad (Ernest, I think) opened a hive in expert fashion and showed how easily bees may be handled, and made plain many mysteries

of the hive. I presume Editor E. R. Root hardly remembers the part he played in that day's program. This was before Wesley Foster had his name enrolled in the records of the Foster family.

In those early days the spirit of bee culture took a strong hold upon our affections. We had visions by day and dreams by night. We saw moving pictures of swarms in the clouds; hives in the shade; nectar in all the blossoms, and honey in ornamental cakes on the poor man's table. The children never seemed to tire of the business or of its fruits, and to this day we all like it. If there is any thing we like better, I suppose it is the opening of a hive just at the height of a first-class honey-flow to watch the bees do business in a well-equipped modern hive.

Boulder, Col.

[The writer of the above is the father of our department editor from Colorado, Wesley Foster.—ED.]

THE GREAT ADVANCE THAT HAS BEEN MADE IN 40 YEARS.

Seeing your call for show of hands for the "forty-year GLEANINGS family," I will say I don't know whether I am strictly in the class or not. I do, however, remember when, many years ago, GLEANINGS was the most interesting publication received, and it still keeps up that interest.

I remember when Novice was running his watch-making shop and keeping bees, or talking bees, or both. At that time he had an attack of bee fever, and had the power to transmit it to others.

I remember when the Bucket hive was used and exploited, and think I can remember when there was a pen picture of the wind-power mill shown in GLEANINGS. The enthusiastic Novice had a way of telling his experiences and troubles that was catching and instructive.

For many years copies of GLEANINGS were filed; but when, following Greeley's advice and coming west, the old copies were left; but to-day GLEANINGS is a welcome visitor, though I doubt if as eagerly looked for as in earlier days.

In a reminiscent mood, what wonderful strides have been made in methods and easy manipulation of hives and accessories! The old Simplicity hive answered its purpose, and was good then; but who would want it now! In those days there was no regular or standard size; and if you ordered your supplies at different times there was likely to be a variation of widths, so supers and hives those days and for some years later were not a smooth-fitting lot as now. The old-time honey-box, with its holes for entrance, answered its purpose too, and the honey was just as sweet, and you possibly got more per colony than when the finished section arrived; but after many vicissitudes the old box disappeared, and the commercial product was perfected and beautiful.

Pages could be written in memories of the business past and gone up to now; but for the present I will merely hold up my hand and still look and pore over GLEANINGS and keep some blessed bees.

Portland, Ore., Sept. 21. EDWIN J. LADD.

Symposium on Beekeeping 40 Years Ago

A Brief Word from Our Subscribers who were with us in the "Windmill Days" when Gleanings was First Started

Please put me down as a subscriber and reader of GLEANINGS from the start.

Denver, Colo., Nov. 4. J. L. PEABODY.

I have read GLEANINGS, I think, since 1872, and have been keeping bees ever since.

Florin, Pa., Aug. 24. H. H. MYERS.

I have 60 colonies of bees. I am one of those who read GLEANINGS in the windmill days.

Gardiner, Me., Sept. 2. O. L. SAWYER.

I have taken GLEANINGS since 1872. It was when it was printed by means of the windmill, and I don't think I have missed a number.

Shellsburg, Ia., Aug. 23. R. QUINN.

Novice's paper has been in my hands ever since it was published. I have a great many full volumes complete, but not all.

Groton, N. Y., Aug. 30. W. L. COGSHALL.

I was taking GLEANINGS when it was printed by windmill power, so up goes my hand. I was 73 years old the 2d of this month.

Lemore, Cal., Aug. 20. J. F. FLORY.

I noted in a recent number of GLEANINGS your call for the names of subscribers of forty years ago. This is to inform you that I was among the number.

Altamont, N. Y., Sept. 10. W. D. WRIGHT.

I was a subscriber to GLEANINGS back in the windmill days. I still keep about 25 colonies of bees, and still read GLEANINGS, but more for the Home papers than for bee culture.

Elm Grove, W. Va., June 24. WM. BITZER.

I am one of the 40-year subscribers. GLEANINGS was then a small pamphlet of two or four leaves, may be. I have always had bees. For many years I kept about 100 colonies.

Bangor, Pa., Aug. 23. JOHN H. JOHNSON.

Some time ago you asked for the names of those who had taken GLEANINGS longest. I have now read GLEANINGS from the first number, which appeared on January 1, 1873, and have the complete set of volumes to date.

Taunton, Eng., Dec. 6. THOS. WM. COWAN.

I am one of your windmill men. I was in Medina two or three times after some bee supplies. I have taken GLEANINGS most of the time, and I think I got more good out of it than any other paper. I am over 75 years old.

Cleveland, O., Aug. 22. H. C. GREEN.

I have taken GLEANINGS from the beginning, having found my first swarm of bees when a boy about 45 years ago. I found it hanging on an oak when I went after the cows. I have kept bees ever since. I am working three yards of about 250 colonies. I have on the hives now about 3000 lbs. of honey. I am 64 years old. I had in one season 10,000 pounds.

Amity, Orange Co., N. Y., Aug. 26. J. W. UTTER.

Noticing your request for the names of those who were subscribers to GLEANINGS in its windmill days, you may count me in, as I've read it ever since its first days.

Otsego, Mich., Aug. 24. O. H. TOWNSEND.

Replying to the call for those who were subscribers 40 years ago, put my name down. I have received every issue of GLEANINGS as soon as out, and have the entire collection.

Hamilton, Ill., Sept. 2. C. P. DADANT.

I am one of your subscribers who began reading GLEANINGS, Vol. I, No. 1, and the writings of A. I. Root in the *American Bee Journal* in the sixties. I bought my first colony in a box hive in 1863 or 1864.

Lewiston, Me., Aug. 22. HORACE LIBBY.

I am one of those who have read GLEANINGS since its first issue. I don't know that I have missed a single number in all that time. I also read the letters of "Novice" in the old *American Bee Journal*.

Derby, Tex., Aug. 22. I. A. KING.

I commenced taking GLEANINGS with the first issue, when published by windmill power; and, with the exception of one or two years in the eighties, I have been taking it continually from the first year of its publication.

Farmington, Pa., Sept. 5. W. L. KEMP.

I think I must have been a subscriber to GLEANINGS for about forty years, for I believe I have received every number from the very first, when it pushed itself out into the great bustling world, scarcely knowing whether to live or die.

Middlebury, Vt. J. E. CRANE.

I commenced taking GLEANINGS 32 years ago, and have been taking it ever since, except two or three years when I first came to Colorado, as I did think, from first impressions, that a bee would starve here. I soon found my mistake, and went into the business again.

La Junta, Colo., Oct. 21. H. S. SHULL.

I commenced reading GLEANINGS in 1872, and have been a subscriber ever since unless, possibly, I missed one year. I do not take the interest in bees I did when I first subscribed, but take it for the Home papers. I hope you, Terry, and C. C. Miller may live to see your centennial.

Monmouth, Ill., Sept. 26. J. H. REED.

In your editorial of Aug. 15 you ask for a show of hands of those who were subscribers to GLEANINGS 40 years ago. I think I can hold up my hand, for I received GLEANINGS from its first number until the present time, and handle bees and raise a few queens.

Council Bluffs, Ia., Aug. 19. EDW. KRETCHMER.

You may place my name on the 40-year list (old windmill times); and, besides all that, I believe I have all the articles written by A. I. Root as "Novice" in the old *American Bee Journal* in Samuel Wagner times. I well remember those days when GLEANINGS was started—I think four copies the

first year, and since I have looked for their appearance with much regularity, and they have always been very welcome. May GLEANINGS live another 40 years, and for those to come after.

Oswego, N. Y., Aug. 25.

F. H. CYRENIUS.

I was one of your subscribers, or nearly so, of 40 years ago. My postoffice at that time was Flat Ridge, Ohio. I have never missed a number since, and have never lost my enthusiasm yet for both the bees and for GLEANINGS. I wish you all long life and prosperity.

Larned, Kans., Aug. 20.

A. H. DUFF.

I believe I have taken GLEANINGS all of the time since its beginning—surely back into the time it was printed by windmill power. I am still in the bee business, having bees in three yards here, in the Catskill Mountains, and also in Colorado; but I am not giving them very much of my own personal attention.

Windham, N. Y., Aug. 23.

O. R. COE.

I subscribed for GLEANINGS during the first volume, and have been taking it ever since, and I feel proud of it. I shall be 72 years old in a few days, and I am in hopes the proprietor may live to see his one hundred. I have kept bees ever since I commenced taking the journal, and expect to as long as I live.

Noah, Miss., Aug. 31.

A. COX.

I commenced to keep bees in 1858, and have been at it since that time. But I feel that it is about time to drop some of it. I go to Florida winters, and I have a few colonies of bees down there which furnish us with a fine grade of honey. I am 64 years old; my health is good, so I think that I can care for bees for ten or fifteen years or more.

Groton, N. Y., Sept. 25. DAVID H. COGGSHALL.

I have not taken your magazine quite as long as 40 years, but long enough to hold up one hand, at least, for I have, with the exception of three or four years, been a reader and subscriber to your magazine for 39 years, and still enjoy it fully as well as ever, especially Conversations with Doolittle and the Home talks, along with lots of other good things with which the magazine is filled twice a month.

Auburn, Me., Aug. 24. MRS. ELLA STOCKMAN.

I read GLEANINGS in windmill days, when you printed the pages diagonally, when you had trouble because the wind did not blow until dark, then came with a rush. We have taken GLEANINGS ever since when we were settled. We sent you subscribers from Missouri, Oregon, and Washington. We could not keep bees without it.

Mrs. JESSIE W. THORNTON.

North Yakima, Wash., Oct. 11.

I have taken GLEANINGS from the first issue, and have had a few bees ever since, and would not like to discontinue as long as I live. I shall be 76 if I live till Jan. 30, 1913. I have always liked Mr. A. I. Root's Home department. I think his talks are very uplifting. His temperance talks are to the point. I also like his gardening and his poultry articles. May he live long and continue to prosper.

Maria, Pa., Nov. 8.

SAMUEL KEAG.

I read GLEANINGS when it contained only a few leaves. They were placed inside of the *American Bee Journal* that I took. I was then keeping bees in California. I have read GLEANINGS and kept bees ever since, with the exception of eight years,

when I lived in Dakota. I shall be 88 years old next month. I was born in Germany in 1824, and have lived in the United States since 1829.

Nerstrand, Minn., Aug. 22.

J. BECKLEY.

I have been looking for that list of gray heads in the honey business in the 70's. I count myself one of them. I think it was in 1872 that I purchased my first swarm of bees in a box hive, and subscribed for GLEANINGS when it first came out. I remember very well the windmill days. I expect to engage quite extensively in the business here, as it is the best location I have found yet.

Ulysses, Pa., Sept. 17. GEORGE A. WALRATH.

We have read your paper since about the first year it started, and have been a subscriber nearly every year of its publication. You signed yourself "Novice" then. The American beehive was about the only hive used, as well as the Peabody honey-extractor. We have a portion of this same old machine yet. We still keep bees, but we have injured our bee business by dabbling in other pursuits.

Plattsmouth, Neb., Aug. 26. J. M. YOUNG.

I note your request in editorial, Aug. 15, for a show of hands of those who took GLEANINGS in the "windmill" days. If you have the old subscription lists you will find my name in Vol. I., No. 1. Then I missed a few months, possibly a year, and have taken GLEANINGS ever since. I still keep bees. My brother and I have 100 colonies now. I am now 59 years old, so you see that I was quite young when I first subscribed for GLEANINGS.

Ballston Spa, N. Y., Aug. 22. J. I. PARENT.

I don't know but I am a forty-year subscriber. My brother and I ran a shop here in 1870. We had a planer and all kinds of saws. We made a lot of Mr. Gould's hives. Along in the 70's I took GLEANINGS. I gave away a good many copies of GLEANINGS to men who got the Gould hives. Mr. Gould sold farm rights to farmers to make and use. We kept from 25 to 50 on hand all the time.

GEORGE RICHARDS.

Harpersville, N. Y., Aug. 26.

[See copy of old bee-hive contract on another page.—Ed.]

I read with much interest your editorial, "GLEANINGS in the Windmill Days," and I wish to state that I have been a subscriber since its first year of publication. More than that, I have every volume bound, and prize them more than any works in my library. I am a five-year subscriber to GLEANINGS, and it is about the only journal that I have the time to read. I was first interested in GLEANINGS through the Home talks by A. I. Root, and have been in the honey business ever since.

Denver, Col., Aug. 22. J. CHARLES FRISBEE.

I have read GLEANINGS most of the time since its first issue, and my beekeeping antedates that time some years. My first bees were purchased June 12, 1858, and I have been in the business more or less ever since. I met A. I. Root at the first annual meeting of North American Beekeepers' Association, held at Cleveland, O., Dec. 6-8, 1871, which was presided over by the late M. Quinby. I have before me the first volume of the *American Bee Journal*, published in 1861; and according to my recollection it is the first publication of its kind attempted in this country. How things have changed since then!

Hendersonville, N. C., Aug. 26. SAMUEL RAU.

I was more than pleased to read your plan for 1913 for the dear old GLEANINGS. I have taken it continuously since it was published as a quarterly, and I can not recall now ever having missed a single number. What a record!

You will remember that, years ago, Stachelhausen and myself were the first to bring out "shook" swarming. Well, we still practice it—couldn't run 1000 colonies for comb honey without the plan, with three people.

Hyrum, Utah, Dec. 12.

M. A. GILL.

I have just noticed in GLEANINGS a call for the old members of the GLEANINGS family to hold up their hands and say "here." I have been a continuous subscriber ever since the windmill days, never having missed a number. For the last five years I have kept no bees; but the fever is still in the blood, and I am keeping posted in the business, and expect, if life and health are spared, to have a nice little apiary in a good location in this, the fairest and best part of God's green footstool.

Ontario, Cal., Sept. 19. J. V. CALDWELL.

I received your notice as to the expiration of my subscription to GLEANINGS. I will renew in a few days. I noticed that you called for the names of the old subscribers to GLEANINGS. I commenced to take it about the first it was sent out. If I remember rightly, it was only a folder of two leaves. I was taking the *American Bee Journal* at that time, edited by Samuel Wagner at Washington. I think it was H. A. King who accused "Uncle Amos" of "shooting poisoned arrows in the dark" because he signed his name "Novice."

Attica, O., Dec. 16.

J. E. ENNIS.

In GLEANINGS for Aug. 15 I see you think it would be interesting to know how many subscribers were left after 40 years, and I think I may claim to have been with you 40 years ago, though I am not certain. At any rate I had dealings with you 34 years ago, and in 1887 I spent a day at Medina, and A. I. Root was digging a well there, I think for a windmill. I know I went about with him for a part of the day. I have no recollection of E. R. Root, though I think I saw him. I am glad to see the advances made in the buildings and management of what has grown from comparatively small beginnings.

ALFRED J. CLARKE.

Longwood House, Oxford, Eng., Oct. 3.

For a holdup of hands for the windmill days, mine is up. Though a school boy in my teens, I got the bee fever while on my father's Virginia plantation; swapped a watch for a bee-tree, and have kept bees and taken GLEANINGS, practically continuously, for more than thirty years.

Well do I remember those early writings of A. I. Root, the windmill power, Merrybanks and his Neighbor, and Blue Eyes and the rest. Specially was I impressed with the moral and religious tone of the Home papers; and it made a good impression on my young life. His conduct of the Sunday-school, family prayers, and religious services in the workshop show a strong character in the right place.

Washington, D. C., Sept. 2. F. P. NASH.

I have not taken GLEANINGS for 40 years, but made its acquaintance in the year of 1878, when I became so interested in it that I procured almost all of the back numbers, and I think I have had and read almost every copy that was ever printed.

It was in GLEANINGS that I first read the A B C; but I have had many copies since that time—had to, to keep up with the times. I hope to have and read every number that is printed as long as

I live, although it is possible that I shall not be able to see to read them myself. If so, I have good children to read them to me. I hope that GLEANINGS will live as long as the world stands, as a monument to its founder, whose writings I have enjoyed so many years.

CHARLES W. PHELPS.

Binghamton, N. Y., Aug. 29.

The undersigned commenced beekeeping in 1860 or '61 in Murfreesboro, Tennessee, and during the Civil war, or soon after, he subscribed for the *American Bee Journal*, published in Washington, D. C., edited by Samuel Wagner. A. I. Root was an interesting correspondent of that journal, writing under the *nom de plume* of Novice long before he published GLEANINGS, which was a very modest publication compared with GLEANINGS of the present day. Your books will probably show that I was a subscriber 40 years ago.

Quinby, Langstroth, Wagner, Alley, Hamlin, King, and many others, not now recollected, beekeepers and authors of that day, have passed away. I came to Florida in 1893, and still keep a few bees.

Tampa, Fla., Aug. 25. W. P. HENDERSON.

I am one of the number who took GLEANINGS in the good old windmill times, and I think I have all of the numbers that were ever printed. While I have not kept as many bees as some, I believe I have had some all of the time except one year, GLEANINGS has always been a very desirable and helpful paper, and somehow I always find the Home department very good.

There, now, as my mind runs over the last 40 years there seems to be a sort of sadness in my heart to think I have made so many failures in my Christian life. However, I am glad I have made an effort to live in the world to come. How I should like to grasp your hand for old and continued friendship! and may we meet beyond this vale of tears.

Dexter, Maine, Aug. 20.

A. R. BODGE.

A TON OF HONEY FROM SIX COLONIES.

I believe that I became a subscriber to GLEANINGS in its early days. I was living then at Lewisville, Pa., and was a beginner in beekeeping. I removed from Lewisville to Oxford, Pa., and continued the care of an apiary, importing Carniolan queens and advertising Carniolan queens for sale, and mailing many hundreds to all portions of the United States. I disposed of my apiary in 1890 and removed to Colorado Springs. From there I removed to this place in 1899, and again secured an apiary of Carniolans which have carried in for my disposal an average of 200 pounds per colony annually. One year, with a hundred acres of alfalfa on my ranch, six colonies gave me one ton of honey. I am still an interested reader of GLEANINGS, particularly Our Homes.

S. W. MORRISON, M. D.

Oxford, Colorado, August 23.

THE SHEEP AND WOOL INDUSTRY AN ADJUNCT TO BEE CULTURE.

I have been a continuous subscriber to the *American Bee Journal* since early in the '60's; and have also been a continuous subscriber to GLEANINGS. I have been a beekeeper continuously for 49 years; have seen a great many changes in the business in that time. The seasons in the earlier years were good; now they are practically a failure. When the sheep industry left our community, the white clover left. That was our dependence for surplus honey. Are not my conclusions correct? Is there anybody who can report abundant crops of white clover

where there are no sheep kept in the vicinity of said crops of clover? Is there any possibility of the white clover ever returning again without the return of the sheep? I think not. If there is anybody else who can produce any evidence to the contrary I should be pleased to hear from him through GLEANINGS. I feel considerably interested.

ALFRED J. FISHER.

East Liverpool, Ohio, Dec. 12.

Forty years ago I was a boy of six, and am not able to remember accurately just when the first number of the magazine came to our house; but I am pretty sure it began with the first number published. At least it was when GLEANINGS was a baby, and from that time until the present we have never missed a number. As soon as I was old enough I went into the business with my father; and at his death, eleven years ago, I had the subscription transferred to myself. "Uncle Amos" is a household word with us. We would feel as much lost without the visits of our bee paper twice a month as we would without our bees. Our children have been brought up on bread and honey, and are a healthy pair of young people, and a credit to the diet.

While not exactly one of the original subscribers myself, you see I was brought up right with the magazine, and hardly know where to draw the line, especially as the change was so slight from my father, C. H. Longstreet, to your present subscriber and friend—

Coronado, Fla., Sept. 9. H. C. LONGSTREET.

I have subscribed for GLEANINGS ever since the first number was published, when the windmill furnished the power, and when "Novice" made some of his engravings with a saw. Before me lies Vol. --, No. 1, headed:

"Novice's GLEANINGS IN BEE CULTURE; or, how to Realize the Most Money with the Smallest Expenditure of Capital and Labor in the Care of Bees, Rationally Considered. Published Quarterly. Medina, O., Jan. 1, 1873."

I have every number published since then, and it has been one of the chief pleasures of my beekeeping life to read and study GLEANINGS.

On Dec. 30, 1898, when GLEANINGS was 25 years old, A. I. Root presented me with a glass dodecahedron, which still adorns my writing-desk.

I may say that I have been a constant subscriber to the *American Bee Journal* since the beginning of 1871, and therefore used to read and enjoy "Novice's" articles in that paper before GLEANINGS was born. May he continue for many years yet to instruct and cheer those who have known him so long.

WM. MUTH-RASMUSSEN.

Independence, Inyo Co., Cal., Aug. 26.

I took GLEANINGS for many years when first published. I was then living in Brookfield, N. H. I moved to Boston, and dropped beekeeping for 16 years. I moved here three years ago, and had bees again within a week. I have had bees upward of 35 years. I never knew a year but that I had more or less comb honey. Our great flow in Woburn is in August and September.

With a protected hive having a cap covering all the supers, a queen that will keep ten frames practically full of brood all the time so the hive is boiling over with bees, I have never failed to get honey. Sooner or later there will be a flow, and ten pounds a day is nothing for such a colony. I have had as high as seven from goldenrod in September in New Hampshire. Massachusetts is an old settled country; and if the editor lived here he would write some very different articles. Shrubbery and hedges like

sumac and clematis and many others cut a big figure. Our town raises more squashes than any other in Massachusetts, and lots of beautiful honey comes from them. There are not a dozen basswood trees in town, and only goldenrod enough to tinge the clematis (cultivated, not wild). Creeping Jenny grows everywhere, a great yielder of fine white honey. My best colony last year gave 70 lbs. in August and September in sections, and according to appearances now it will beat it this year.

Woburn, Mass., Aug. 30.

E. C. NEWELL.

I am only a boy yet, 60 years old; but I kept bees when I was 17. The first bee book I ever read was an old one my father had—The American Beekeepers' Manual, written by T. B. Miner in 1849. It marked the change from the straw and log gum to a square box with a small box on top. The next after that was a book written by Moses Quinby, I think; but my start in beekeeping was due to a neighbor who sold his place and wanted me to take his bees on shares. I think there were 14 colonies. The hives were 14 inches wide, 14 inches deep, and about 20 inches long. The whole back was a door. The bees' part was 12 by 12 inches square, with glass in the back. On top of that were placed two boxes, 6 by 6, and 12 inches long, with glass in the end, all home-made; and I still have two hives, with no bees in them, that I made in 1879.

I knew of Mr. A. I. Root 40 years ago, and I think I also read GLEANINGS from the first.

I have never been a big bee-man, nor kept bees all the time, as I have sometimes been where I could not; but whenever I could I had them, and now I have nine colonies in our back yard in the city of Hudson, and I love the little scamps as well or better now than I did 40 years ago; and I remember as a boy I used to love to take a book or paper and sit among the hives, and read, and hear the bees hum. It was music; and how I used to watch them pile in ahead of a shower!

Hudson, N. Y., Sept. 1.

H. C. NIVER.

I am not certain, but I think I read GLEANINGS from nearly if not quite at the start, as I had the old *American Bee Journal* when published by Samuel Wagner, Washington, D. C., and A. I. Root wrote for it under the name of "Novice"; and those pieces written by him were the first looked for. I have been a subscriber a large part of the time since GLEANINGS has been in existence, and have kept bees since June 22, 1856. I have 19 colonies at present, and have had Italian queens from different breeders. I introduced two queens this year from a breeder who advertised four and six banded bees; but the first queen produced very fine three-banded ones, and it is not quite time yet for eggs to hatch from the second one.

This section is not very much of a honey country; 80 to 90 lbs. is as much as I have ever taken in surplus of honey in any year. In all the 56 years I have kept bees, 500 lbs. is as much as I have taken in comb and extracted honey in any season from 12 to 15 colonies, spring count. I have always been able to sell all my honey at home, as people knew for quite a distance that they could nearly always find honey, either comb or extracted. I usually get from 20 to 25 cents per lb. for comb honey, and 20 for extracted honey put up in jelly-tumblers.

One thing more. I am a believer that queens mate two to five miles, quite often, from home, as no one less than five miles from my farm has ever introduced any Italian queens; and bees in three different yards, 1½ to 2½ miles apart have become mixed with Italian blood. If not from drones from my small apiary, how then?

GEORGE S. WHEELER.

New Ipswich, N. H., Sept. 25.

Our Homes

A. I. ROOT

Blessed are they which do hunger and thirst after righteousness, for they shall be filled.—MATT. 5:6.
And in his law doth he meditate day and night.
—PSALM 1:2.
Oh how I love thy law! it is my meditation all the day.—PSALM 119:97.

Dear friends, our Medina people have asked me to dictate a Home paper concerning the way in which GLEANINGS was started forty years ago, to go along with these letters of those who have taken GLEANINGS forty years or more, as given in this issue. May God help me to deserve better the many kind words that have come in these letters from so many of the old veterans. The names as I glance over them seem so familiar it is hard for me to realize that forty years have passed since I first became acquainted with the writers. I should like to send a kind message to each one personally if the space permitted.

I have before remarked, that all through my life I have greatly enjoyed the work of hunting up God's gifts; and I believe I speak truly when I say that I enjoy even more passing these gifts along to others. Some of you may think strange to notice the beautiful texts which I have chosen to head this short autobiography. Now, while I agree that the main purpose and meaning of these texts applies to spiritual things, yet I also feel that they may apply to our daily life, and to the industry in which we are engaged. If our industry and occupation are for the benefit of humanity, we are indirectly seeking the kingdom of God and his righteousness; and we have a right to appropriate these beautiful texts to the lives we are living and to the calling we are following.

I have told you in the preface to the A B C book how it was that my attention was first started toward bee culture. When my father moved on to the old farm in Medina County, when I was about twelve years old, I was much interested in gardening, especially in studying the catalogs and testing the new fruits, seeds, etc. Finally I subscribed for and read with great attention a little periodical called the *Northern Farmer*. It was edited by T. B. Miner. One of the writers in this issue refers to Miner and his book on bees. I think I got the book and was planning to get some bees; but for different reasons it was put off until some years after my marriage and I had a home of my own. The A B C book tells you briefly what happened at that time. After the truant swarm of bees was captured, and I had begun to make them my study, in my ignorance in regard to their management

they soon swarmed out; but my enthusiasm was so much aroused it was not to be stopped by this occurrence. I found a neighbor about half a mile away who consented to sell me an old box hive. With some ropes it was hung on a pole one night after dark, and a kind friend assisted me in carrying it about half a mile to my own home, where it was placed in the loft of the woodhouse. To make sure, I was up before daylight and watching to see the first bee make his appearance and start off. I rather think it took some calling to get me to come to breakfast, because I was anxious to see the first bee return with a load of pollen or honey. From that time forward bees were a craze with me. I was at the time a watchmaker and jeweler; but every old farmer who came into my place who knew any thing of bees or had ever kept bees was pumped until he was, I fear, sometimes glad to get away. I borrowed (and later subscribed for) about all the farm papers published at the time, in order to find out all I could about bees and bee culture. The *American Agriculturist*, by the Orange Judd Company, was then my particular reference. I made an early trip to the city of Cleveland, and carefully looked over all the books and every thing else they had in regard to bees. I think that it was exceedingly providential that I got hold of and chose "Langstroth on the Honeybee." I soon found that Langstroth was still alive, and through him got in touch with Samuel Wagner. I learned that the *American Bee Journal* that had been published for two years was stopped on account of the war. After some correspondence with friend Wagner I got him to recommence the publication, promising to write for it regularly. Several of the friends in the above letters allude to these letters written under the *nom de plume* "Novice."

In my search for knowledge in regard to bee culture I soon ran against certain patent-hive men. I visited A. J. King at his factory in Nevada, Ohio, and bought an individual right and took the agency for the American hive. When I afterward suggested to the *American Bee Journal* that King's American hive was an improvement on the Langstroth hive, my good friend Wagner took me to task, explaining why movable frames were better than frames at fixed distances.

Later on, under the signature of "Novice," I attacked various patent hives, showed up their defects, and why they were

greatly inferior to the Langstroth hive; and, among other things, I advised against the use of the American hive in place of Langstroth's. Mr. King at this time in his journal, *The Beekeepers' Magazine*, accused* me of "shooting poisoned arrows in the dark" because I didn't sign my full name, A. I. Root, to my communications.

I soon got track of Italian bees, and found the only queen that was to be purchased so late in the season (for it was then along in the fall) was one in the possession of L. L. Langstroth, for which he wanted \$20.00. I told you in my A B C book how I sent off my \$20.00 and watched anxiously for the bee. Of course I became the laughing-stock of friends and neighbors for paying \$20.00 for a single bug; but later on, when I secured a barrel of honey from one single colony of Italian bees in one summer, people who criticised concluded there must be method in my madness after all.

Of course, my success was written up in the *American Bee Journal* as well as in our Medina paper. Interest in bee culture started up there and then.

Let us take up my first text right here. While it can not be said that I was literally hungering and thirsting after righteousness, I was in reality hungering and thirsting to know more about bee culture. It was my study and my theme day and night. Not only were books and papers read, but an observatory hive was placed in the window where I slept, and I spent a great part of every night in watching them by lamplight. I saw the queen-cells built, saw the queen emerge from her cell, saw her take her wedding-flight, witnessed her return, with the evidence of impregnation, and none but those who have passed through a similar experience can realize with what joyous enthusiasm I verified the statements in the books. I began to get a library of all the books published that I could get hold of—not only standard works but those put out by patent-hive venders. I soon commenced the task of sifting the wheat from the chaff. I can not recollect now that I had any particular desire to benefit humanity, though I improved bee culture. This is true, however: I have all my life, I believe, been against any sort of work or system to defraud humanity, especially the honest till-

ers of the soil. When I saw what was being done in the way of patent hives, I proceeded to investigate and protect the honest people who had no money to spare where there was no need of sparing it. At the time the war broke out, I was manufacturing silver jewelry, and had quite a number of hands in my employ. I collected my agricultural books and papers and set a clerk to work to hunting up the addresses of as many people as she could find that were interested in bee culture. After having read of the German honey-extractor, and seeing a rude cut of one, I set about making one, and the barrel of honey that I secured from a single hive in a single season was by the use of this old metal honey-extractor. When I saw what the Italian bees might do I said, "Friends, the time is coming when honey will be on sale (like butter and eggs), not only at every corner grocery, but every day in the year." I have lived to see this almost verified; and with our new parcel post it may be more than verified.

It soon became necessary for me to have a printed list of the things in regard to bee culture that I had for sale, and new editions of this price list were needed so frequently that I finally decided, in order to save an endless correspondence, I would have to get out a quarterly bee journal. The first number was accordingly sent out to as many addresses as I could collect in the way which I have indicated. I believe it was also advertised in the *American Bee Journal*, the journal I had been writing for, for a year or more past. The price of the quarterly was to be 25 cts. per year; but it was almost immediately received with such enthusiasm that I changed it to a monthly at 75 cts. per year, almost before the second number. Since then the growth has been steadily upward. It is still growing now in its 41st year. I believe there has never been a time or a year in which the subscription for any one year was less than it had been for the year before. I visited Mr. Langstroth in those early days, and he paid frequent visits to our place in Medina; and many were the long talks and pleasant hours that we spent together.

Let me digress a little right here. My old mother used to make visits frequently at our home and look over my bee-books and the bees, and listen to my talks on bee culture. While she was not particularly interested in bee culture, she was always from first to last deeply interested and full of enthusiasm in seeking the kingdom of God and his righteousness.

Let me go back still further in my story. When I was two or three years old, and

*In later years this same Mr. King, overlooking or forgetting the past, possibly seeing that A. I. Root's judgment concerning the relative merits of the two kinds of hives was correct, wrote my father a very kind and appreciative letter. The verdict of later years was and has been, unquestionably, in favor of the Langstroth frame and hive, while the King hive and frame have been all but forgotten. The King frame was almost immovable after it was well glued up with propolis.—E. R. R.

my parents lived in the old log house out in the woods on the farm, one cold frosty morning, when there was a little snow on the ground, father and some of the neighbors were planning to brimstone a hive of bees to get the honey. I asked a number of questions that no one could answer, and my curiosity was so great that, although told I must not even look outdoors because I had been suffering from a severe cold, I finally escaped the attention of mother and the rest, pushed through the partly opened door, and got out into the crowd around the beehive before anybody noticed it. Child-like, I slipped down and got my hands in the snow. They took me indoors and warmed me before the open fireplace. Notwithstanding all their care, I contracted lung fever, which came so near taking my life that the doctors gave me up. My good mother didn't give me up, however, even if the doctors did. She kept on doing every thing she knew how, and praying that the little life might be spared. Some one inquired afterward what doctor it was that brought me out of that low spell. The Christian doctor, however, replied that no doctor did it; it was my praying mother who saved my life.

Now to go back. When my mother used to see me so engaged with my books on bees that I could not drop them, even day or night, she used to say something like this: "Amos, the time is coming when you will read your Bible with as much enthusiasm and interest as you are now reading these books on bees." I laughingly made some sort of reply; but later on, as these older readers of GLEANINGS will remember, I dragged my "religion into an industrial journal," as some expressed it. Some good business men and even church members smiled at my unusual proceeding. But I, believing that I was under the influence of the Holy Spirit, wisely kept quiet, and kept on in my course, as you will see if I relate one little incident.

A large business firm in the East made a mistake and sent me a consignment of goods which I didn't order, which would be rather expensive to return. After some correspondence I told them that, in order to save them expense, I would try to work off the goods. I did this by putting them on the fairground in the counter-store business that was my hobby for a time. When I informed them the goods were all sold, and enclosed check, there came a reply something like this: "Mr. Root, we will confess that we were prejudiced against you. We were told that you were a religious crank, and had the habit of mixing

religion and business. Now, if this is the way you propose to mix religion and business, bring it along; the more of it the better; it is *exactly* what the world is suffering for."

One reason why GLEANINGS has prospered is, I think, that it has always set its face so determinedly against selling secrets and frauds. I have been all my life more or less in touch with the experiment stations, not only in Ohio, but others, and they have repeatedly said that no good thing ever came to science or art or industries through a secret sold for a certain sum of money. Our Ohio experiment station is very decided in regard to this point. Yet at the present time we are told by the papers that millions of hard-earned money have been going and are going constantly to fakers who make it their business to rob people of their hard-earned money, especially sick people. Now, GLEANINGS has from first to last endeavored to protect people from frauds of this sort. Any advertisement that is sent in of this kind, it has been my custom for years to ask for sample of what they had to sell for a certain sum of money. Many refuse to do this, thinking it is, perhaps, none of our business.

In order to succeed in any business at this present day and stage of the world's industry, it is almost a necessity that you be "hungering and thirsting" for every thing that is to be known about the business you are engaged in. Better still—yes, ever so much better—you should be hungering and thirsting after *righteousness*. I believe one of the hopeful things that we can thank God for at the present time is that the whole wide world is more and more hungering and thirsting after righteousness instead of hungering and thirsting for opportunities to get a hand into some other man's pocket without his knowing it. The most pressing need of the present day and age of the world is for men for important offices who are hungering and thirsting after righteousness, instead of hungering and thirsting for an opportunity of defrauding the people whom they have sworn to protect.

It is true that, during the past forty years, there have been various jangles and disagreements and difference of opinion; but, may the Lord be praised, they have been finally settled, almost without exception, in a peaceable and amicable manner.

The fashion of filling the pages of a bee journal with accounts of quarrels and disputes, instead of having the pages devoted to the dissemination of useful and helpful knowledge, has, for the most part, passed

by, and I thank God for it. Editors of bee journals of the present day seem to be on most friendly terms, and ready to lend a helping hand whenever it may be required. It has been frequently remarked, and I believe truly, that the beekeepers of our land occupy a higher standard of morals than those engaged in almost any other occupation.

•THE AMERICAN TOBACCO CO. AND THE CRUSADE AGAINST INTRODUCING CIGARETTES INTO CHINA.

We clip the following from the *Union Signal*. It is a letter from Mrs. Chauncey Goodrich, President of the China W. C. T. U.:

Up to the year 1900 many men and women were given to smoking tobacco, though as the bowl of the ordinary pipe in use was so very small the evil effect was slight; but since 1900 tobacco companies have awakened to the idea that China is an excellent field for the sale of cigarettes, and have left no stone unturned to introduce them into the country. Their agents have gone into the most remote places of the most distant provinces, as well as those provinces bordering on the coast. The walls of cities, villages, and even hamlets are covered with large flaming posters telling of the great value of the cigarette in *banishing fatigue*, awakening an appetite, and also relieving phlegm gathering in the throat in the morning—thus making one feel generally happy and able to accomplish more work. Pictures of women are, in some cases, placed in the boxes, while at each stand where cigarettes are sold, large pictures are on view. To introduce the cigarette, officials and others have been presented freely with large boxes of them, and in some cities small boxes have been thrown in at every gateway or store with the hope of creating the habit. The finest printing-press in Shanghai is owned by the American and English Tobacco Company, which last year employed 125 European salesmen, besides countless Chinese. The ease with which the cigarette is carried and smoked has increased its use so greatly that one now sees men, women, and even little children under five, yes, even three years of age, smoking them, and the shaking hand and trembling jaw of the cigarette smoker are very common among young people. This use of the cigarette is day by day undermining the health, affecting the brain, and blighting the morals of the Chinese. The tendency to tubercular trouble, which has carried off more of our brightest pupils in mission schools than has any other disease, makes the frequent use of the cigarette unusually perilous in China. It is with real pain one sees this evil thing taking the place of food in the families of large numbers of working people who can ill afford to forego nourishment. No small effort has been made to inform the people of the extreme harmfulness of the cigarette, and to unite them in a crusade against it. This has been very effective in certain places, notably Foo Chow, where it is said cigarettes have been largely driven from the city. In Peking we have posted on the city walls large posters, 3000 in all, dealing with the nature of nicotine, the effects resulting from its use, and stating what steps different nationalities are taking to prevent the formation of the habit among minors. These posters were prepared on behalf of the W. C. T. U., but the Tract Society printed them and created a sale

for them in many provinces, and also for a folder in different form. More than 30,000 of each were sold or given away in one year. In one city in Shansi, the official thanked the missionary who had the posters placed on the city walls, saying foreigners were too often ready merely to profit from the Chinese, and that they greatly appreciate, therefore, the efforts of those who are seeking to prevent injury to them.

To the above the *Signal* adds:

Friends, does not God call us to be more courageous, to fight—yes, fight—against these gigantic evils of our race and every race that are unfitting men and women to become in body, mind, and soul that which God meant them to become?

LIQUOR, SNAKES, REVOLVERS.

Snakes, intoxicating liquors, and revolvers can not be sent by parcel post. Significant, isn't it? What a combination! How appropriate! The prohibited articles are much alike. Any kind of snake causes the average person to shudder. Few persons want any thing to do with snakes, dead or alive, real or imaginary. There is an affinity between snakes and liquor; and then add revolvers and you have a harmonious trio. Liquor calls for revolvers, and liquor produces snakes. Revolvers, snakes, liquor—these three—but the greatest agency for evil is liquor. Uncle Sam knew his business when he grouped these agencies and forbade them the use of the parcel post.

We clip the above from the *American Issue*, and breathe a hearty amen to every word of it, and also thank God that "Uncle Sam" is, to some extent, waking up.

"UNCLE SAM IS OUR PARTNER."

A circular issued by a mail-order liquor firm bearing the words "Uncle Sam is Our Partner" was displayed in the Senate chamber one day last week by Senator Kenyon as an illustration of the extent to which, he said, the United States was taking part in the violation of local prohibition laws in "dry" States. Congress adjourned, however, without passing the Kenyon-Sheppard bill to prevent the lawless importation of liquor into dry territory. The liquor forces have all along declared that the bill shall not pass. It remains to be seen. If the allied forces of greed and illicit gain and anarchy and beastliness can stand up and defeat law and order and humanity and home, and morals and truth and goodness, and good men and good women and God, they can not continue to do it indefinitely. It is a fallacy and enormity to try to uphold and bulwark the murderous liquor traffic by the approval and sanction of the Government. Every righteous heart knows that it is wrong in the sight of God. A thing that is morally wrong, and that is actual anarchy under the laws of many of our States, can not be made any thing else than an infamy by all the contortions of all the constitutional lawyers, nor by all the threats and bribes of liquor-dealers who wish to have it made legal for them to commit crime.—*Herald and Presbyterian*.

The A. I. Root Co.:—

I have just received the book which I ordered from you, "Wax Craft," and have had time to read only a few chapters in it; but I think it will be very helpful to me. I received the A B C of Bee Culture and The Honeybee, by Langstroth and Dadant, all of which I received several days ago, and in connection with my observations I have read them all. I find that they are splendid studies, even for the man with a small apiary. I am a young man, and these books have opened up a new world to me.

Editorial

DEATH OF D. H. COGGSHALL.

WE were pained to learn that our old friend and valued contributor, D. H. Coggs-hall, dropped dead the 18th of January while waiting for the train. He was just starting to spend the winter in Florida, as has been his custom for several years. Details will be given later.

DEATH OF GRANDMOTHER WILSON.

OUR readers will remember how, two years ago, on page 659, we showed a picture of Grandmother Wilson in Dr. Miller's family, who had been making honey one of her chief articles of diet for many years, and who, at the age of 93, seemed to be strong in body and mind. We have been in Dr. Miller's home, and have seen this remarkable old lady whose life was indeed sunshine filled with the love of God and the hope of the beautiful hereafter. Dr. Miller thus speaks of her death:

Dear Ernest:—You will recall Grandmother Wilson sitting in her window amid the sunshine and flowers. The sunshine and flowers are still there, but the brightness of her presence is gone. January 24, when within 22 days of being 94 years old, she very suddenly breathed her last without a struggle, at 10 P. M., having retired at her usual bedtime, without having been confined to her bed for a day. I had not realized how empty the house would seem without her.—C. C. M.

HAY OR STRAW FOR PACKING FRAGILE ARTICLES LIKE SECTION HONEY.

ONE of our correspondents, in the Heads of Grain department, Mr. E. F. Robinson, of Canada, makes the statement that "straw once flattened remains so, to a certain extent. . . . I always use hay, as it is much more resilient than straw." This is interesting and valuable if true, and we are inclined to think it is true or our correspondent would not say so. Straw, however, is a commodity that can be found in all of the eastern States and many of the western, while timothy hay, the kind referred to, will be found mainly in the northern and eastern States, and a few States east and north of the Mississippi. If hay is more resilient

than straw, let us by all means use it in our comb-honey carriers and in our packing-boxes. The matter is well worth investigation on the part of our comb-honey shippers.

DANGER FROM COLD IN FEBRUARY.

FROM all parts of the country came reports of warm weather in January. In some localities, even in those where flying days in January are usually very infrequent, the bees were able to get pollen, so that brood-rearing was started in earnest. All this means that there is danger of a considerable amount of brood being chilled during this cold weather in February which seems to be quite general.

Another bad feature resulting from excessive brood-rearing in January is that many colonies will run short of stores; whereas if the weather had been cold enough to prevent brood-rearing until later on they would have had plenty.

THE OHIO STATE BEEKEEPERS' CONVENTION.

THIS convention was held at Columbus in one of the recitation halls of the State University, a little way out of the city. There were present Mr. C. P. Dadant, of the *American Bee Journal*; Mr. E. B. Tyrell, of the *Beekeepers' Review*, and Secretary of the National Beekeepers' Association; also Professor W. A. Matheny, of the State University at Athens; and Professor J. S. Hine, of the State University, Columbus. In this connection it is proper to remark that both universities have already installed (or are about to do so) lectures and brief courses in apiculture under the charge of the professors mentioned.

The first session of the convention was quite well attended, made up of beekeepers from various parts of the State, and students in the agricultural department of the college, particularly those who are interested in bee culture. Of course we had with us the Secretary, Prof. N. E. Shaw, Foul-

brood Inspector and State Entomologist in the Department of Agriculture, and his deputy inspector, Mr. Morris, who is also President of the Association. Space will not permit us to give a report at this time.

PARCEL POST FOR BEESWAX.

A FEW days ago a beekeeper sent us five or six pounds of wax by parcel post. The wrapping consisted only of paper and strings; and when the parcel reached us, the wrapping was nearly gone, and the strings just barely held together the cakes of wax. There is no reason why beeswax can not be sent by parcel post provided it is put in a strong burlap sack. The ordinary paper wrapping is insufficient to stand the rough handling by mail. In fact, we may say that beeswax in small quantities should never be sent in any thing less secure than a wooden box or a good strong sack. Paper wrapping, even by express, has been broken too many times to warrant the risk by either express or mail in a paper wrapping.

THE CALIFORNIA WINTER FREEZE AND ITS EFFECT ON THE MOUNTAIN-SAGE CROP.

MR. R. M. SPENCER, of the R. M. Spencer Apiaries Co., of Nordhoff, Cal., writes that the freeze in that State will cut the sage-honey crop more than half. What is true of sage is also true of the sumac, which they get in July. Besides the freeze, they report that they have had no rain up to Jan. 14; and he therefore thinks that California will not do much this year in the way of furnishing sage honey. This is regrettable, as the mountain sage is getting to be a very popular and good-selling honey.

Later:—Almost in the same mail comes another letter, dated Jan. 17, from Mr. Allen Jenkins, of Westgate, Cal., who says they are having copious rains, and everybody is rejoicing. As this is three days later than the letter from Mr. Spencer, we are in hopes that the needed rain has come in his locality as well. See also Mr. Chadwick's statement in his department.

GOOD BEE LOCATIONS IN OKLAHOMA AND KANSAS.

In an early issue we shall give an account of our trip to Oklahoma and Kansas, and something concerning their great possibilities in the line of beekeeping. Alfalfa is being grown very largely in those two States. Strange to relate, bees and beekeepers have not followed in its wake; yet alfalfa in Kansas and Oklahoma yields honey—not so bountifully, of course, as in

the irrigated regions, but enough so that beekeeping can be made a very profitable industry—especially so as the country is not overstocked. The beeyards will necessarily have to be small, and within short distances of the rivers or creeks and valleys. In Oklahoma, cotton is yielding at present a large amount of honey. The climate of both States is delightful—particularly that of Oklahoma. We do not wonder that there is a great rush of eastern people into the State. There are, of course, “suckers” and fakirs by the thousand. But the State is full of honest men; and if one will keep his eyes and ears open he can learn the truth. Right here let us say that some of the land in both States is comparatively poor, because it is away from water or too near the rock; but in the valleys and along the course of creeks and rivers there are many fine farms, and also some excellent bee country. More anon.

FOUND PACKAGES OF BEES NOT ADMITTED TO THE PARCEL-POST PRIVILEGE.

In this issue, in the Heads of Grain department, page 131, a correspondent asks if bees without combs can be sent by parcel post. In our reply we have explained that this can not be done, and why. The reason we make mention of it here is to make sure that no one make the attempt to send a pound or two of bees by mail with the same result that happened 35 years ago, when even queen-bees and their attendants were barred from the mails. While the local postmaster would refuse to accept such a package, he *might* let it go through, with the result that we might have serious trouble on our hands. The Postmaster-general, or, rather, the Third Assistant, has more authority than any Representative or Senator, in that he can put a ruling into effect that might make or unmake the entire queen business in the United States. Let us proceed cautiously; and when we have perfected a combless cage by which we can send bees by the half-pound, pound, or two or three pounds by express, we shall then be in better shape to go before the Department and ask for a ruling than we now are.

Later:—The expected has happened. Bees sent by parcel post in a poorly-made cage “broke loose.” Particulars in next issue.

REPORT OF APIARY INSPECTOR OF TENNESSEE.

In the eighth annual report of the Tennessee State Board of Entomology, Dr. J. S. Ward, newly appointed as State Inspector of Apiaries, gives a good report of the first six months of his commission. The month of June was spent in inspecting in

Davidson, Maury, and Rutherford counties, only one yard being found infected, and this was treated.

The Tennessee agricultural train started on its tour over the State July 1, and on July 4 Dr. Ward was instructed to join the train with an exhibit which he had hastily prepared, consisting of an observatory hive, supplies, various races of bees, etc. The bees actually working proved one of the most attractive exhibits of the train. Demonstrations and instructions in beekeeping were given at every stop, and a hundred open-air lectures were given besides.

The inspector has found some trouble in getting reports of disease, due to a possible fear on the part of the owners that the colonies may be destroyed, or because of discouragement or indifference.

The work for the winter includes a continuation of the illustrated lectures and demonstrations in the field, and an energetic campaign is to be carried on for the purpose of getting statistics in regard to bees which will include the name and address of the owner, the number of colonies, source of honey, whether comb or extracted or bulk comb honey is produced, average yield per colony, diseases, etc.

OUR APICULTURAL SCHOOLS: ARE THEY MAKING MORE COMPETITIVE PRODUCERS RATHER THAN HELPING THOSE ALREADY IN THE FIELD?

THE initial article in this issue, under the heading of General Correspondence, by Mr. J. L. Byer, discusses the question whether the apicultural school at Guelph is not making a mistake by making more beginners when it should rather take those we have and make better ones of them.

Mr. Byer and Mr. Holtermann, as well as the editor of the *Canadian Bee Journal*, apparently feel that these new recruits do not fully understand the difficulties that confront the beekeeping industry of the day. From their point of view these beginners go into beekeeping, run up against foul brood, then go out of the business, leaving the industry in a worse condition than before.

Let us assume for argument's sake that the apicultural schools at some of our agricultural colleges are making recruits rather than instructing the beekeepers already in the field. We have visited practically all such schools in the United States and Canada; and the brood diseases, or any other bee disease, so far as we have been able to see, has been properly presented to the students. Not only that, but the schools have taken pains to point out fairly and candidly some of the difficulties, so that the novice,

when he takes up beekeeping, will be informed in advance of the problems that he will have to solve. The student comes in actual contact with an instructor who thoroughly understands the business. In many cases they have access to a full equipment. The practical management of bees is fully explained so that the novice or old timer can go out into the world, learn how to handle them, and then go into the business with a better knowledge of when and how to proceed. Such a beginner, ninety-nine times out of a hundred, will be more careful about letting bee disease get into his apiary than the average "old-timer" who does not fear foul brood, and who feels that he can cure it when it does come. It is a lamentable fact that many of the professional beekeepers either do not care if they get disease or do not understand; and if our agricultural colleges did nothing more than to stir up these men to the real danger that lies before the practical honey-producer, they will have served their purpose. They are doing this very thing.

But, as Mr. Pettit points out in his reply to Mr. Byer, his agricultural school is composed largely of students *who are already in the business*, to the extent of nineteen out of twenty. What is true of the school at Guelph, Canada, is to a great extent true of similar schools in the United States. Having visited all of them, and having seen the class of work that they are doing, we are convinced that they are putting the industry as a whole on a safe and sane basis.

It is exceedingly difficult to get an appropriation in the first place sufficient to carry on apicultural schools with a competent man or men in charge; and we can not but regard it as unfortunate that criticism of this sort should arise at this time; for if there is any institution that is protecting the beekeeping industry, outside of our books and journals and our foul-brood inspectors, it is our apicultural schools. The more of them the better. We believe we have traveled over more bee territory in the United States than perhaps any other person in this country. We have just finished a trip of 2500 miles visiting beekeepers and two institutions where bee culture is being taught. Careful examination of all the facts in the various localities convinces us that we have *ten times as much to fear* from the inroads of foul brood and price-cutting from the don't-read-the-journals class of beekeepers as from any other class we have to deal with. Those who do not read a bee journal probably do not read even agricultural papers, and much less are they in touch with our apicultural schools.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

THAT symposium of 40 years ago, p. 97, takes you back, doesn't it? If those 50 or more young fellows could meet now, what an interesting convention they could hold! I'd like to be there to hear them.

OH YES! Alfred J. Fisher, p. 100, there can be abundant crops of white clover without sheep. It is my chief dependence as a honey crop, and I don't know of a sheep within three miles. For best results white clover must be grazed to make its season longer; but I don't know that it makes any difference whether it is grazed by sheep, cows, or some other stock.

THIS kink is from Arthur C. Miller: "Wrap a queen-cell in a piece of thin foundation, bringing it snug to the cell near the tip (which just protrudes), pinching the foundation together over the cell-base, when the cell will be safe from attack, no matter what colony you give it to." Handy in case a cell has been injured, or where a colony is not yet fully conscious of its queenlessness.

THE windbreak question is well discussed, p. 38 and p. 55, and that reminds me. Years ago my apiary was surrounded by growing corn and dense shrubbery. In the center of the apiary, combs melted down and the honey ran on the ground. It was not caused by the direct rays of the sun, for the sun never shone on the hives all day long. It was because the dense growth prevented the circulation of the air. If that kept the hives warm in summer, why should it not have the same effect in winter?

MR. EDITOR, I have a large stock of ignorance about outdoor wintering. So I may repeat, in all good faith, the question I asked on page 74, whether you ever saw a solid comb of honey projecting down through the cluster of bees in winter, applying it to bees wintered outdoors. Reasoning upon the case I should say that the same rule would hold outdoors as in cellar; and so while empty combs would be found below the cluster, the bees would never allow honey below the cluster. But reasoning is not always safe, and I may be utterly wrong. Can we have a positive statement of fact? How is it at Medina, and where J. L. Byer lives? [We can not answer your question directly, but we do know this: In early winter, when a cold snap comes on, and after the bees have been fed up so that their combs are well filled except the winter nest, you will very often find the cluster clear up to the top of the brood-frames and over

them. An examination shows that the bees are above the honey, because we can look under the cluster when the sunlight is right. Yes, sir, 'e; we feel very sure we have had many cases like this where the combs of honey project below the cluster. It could not be otherwise, or else the cluster would not be at the top. Now for your side of the proposition, we may say the *normal* position of the cluster is down near the bottom-bars next to the entrance, with the honey above.—ED.]

LOCK-CORNERING of hives, or dovetailing, mentioned p. 91 as one of the improvements of the past 40 years, recalls the prophecies that were made upon its introduction that it would be an utter failure. Hives with that feature could not last; the corners would pull apart; the moisture would work in, rotting the wood, etc. But the hives didn't seem to mind the criticism, and to-day not many would want hives without the condemned feature. [Yes, we remember very well the prediction, and how we were scored for putting out the lock-cornered hive 25 years ago; but they were never more popular than now. All the manufacturers in the country have adopted the principle. It was a case where theory did not "dovetail" with actual practice, because the "dovetailing" actually held. We have now in use hives that were never painted, and which are still good for 25 years' use so far as the dovetailing or lock-cornering is concerned.—ED.]

ARTHUR C. MILLER says, p. 81, "Another word about soft sugar and I am done—no, not out of sputter, but just holding up for a future time." That recalls a story of another individual who was "not out of sputter," but who was short on another commodity, and who was "just holding up for" a fresh supply:

A wide-awake five-year-old had been giving his mother all sorts of trouble one day when she had company. Finally she shut him up in a closet. His screams could be heard a mile or less. Suddenly they ceased, and there was a dead calm. His mother waited in vain to hear him say, "Mama, I'll be good." Visions of her darling, dead from suffocation, floated before her, and she opened the door, only to find him calmly seated on the floor. "What are you doing, my son?" "Nothing. I spit on your new hat; I spit on your new coat; I spit on your new dress; and I'm just waiting for more spit."

SIFTINGS

J. E. CRANE, Middlebury, Vt.

On page 755, Dec. 1, Dr. Miller and the editor discuss shipping cases somewhat, and tell how to ship safely. I want to add that it requires much more careful packing to ship honey safely in late autumn and early winter than in warm summer weather.

* * *

"He was an honest man and a good citizen" is said of J. S. Harbison, page 679, Nov. 1. Why? Because he believed in the fatherhood of God and the brotherhood of man, and he has left to the world what is worth more than heaps of gold and silver.

* * *

"Darn a veil, anyhow!" says Arthur C. Miller, page 809. Thank you. That is about the way I feel. I have submitted to hundreds of stings rather than wear a veil. To have that veil everlastingly between your mouth and a nice tidbit of honey as you open a hive, or a fat strawberry, or a plum, or a cluster of grapes, is provoking. But if you must wear one, there is nothing better than the one Mr. Miller describes.

* * *

I am glad Dr. Miller is going to try extracting honey, page 790, Dec. 15, with part of his bees. There are several advantages in doing so. There is lots to learn, and then you will find some customers who will pay a good price for it just because *you* produced it. And, again, your supply of wax to be worked into foundation will be largely increased. We have between two and three hundred pounds on hand ready to send away to be made into foundation. That makes quite a saving in supplies for the summer of 1913.

* * *

In the discussion of flowers Mr. Ryan and Lovell agree on one thing: "that the poppy contains no nectar." Shall we ask why? While in the southern part of the State last summer a gardener showed me a long bed of poppies, and said that bees worked freely on them in the forenoon, but that large numbers of the bees were so overcome by the narcotic element of the plant that it would be hours before they would all be able to return to their hives. Now, we know that honey often, if not always, partakes more or less of the nature of the plant from which it is gathered. Thus the honey from the thoroughwort is quite bitter. That from the white daisy tastes as the flowers smell; and may we not readily conclude that, had the poppy produced honey, it would have contained so much of the

powerful narcotic principle of these plants as to be destructive to bees where it grows freely in the grain-fields, as in many places in Europe? How kind of the Author of nature to withhold nectar from the poppies, and give instead a good supply of pollen!

* * *

A SUMMARY ON WINTERING.

The subject of wintering bees in the colder parts of the country is not as well understood as it should be. I wonder if I can sift out some of the main facts so a child can understand them.

If the bees of a given colony have good stores of honey or sugar syrup there are just two other facts to be remembered—*protection from cold, and dampness.*

Why should they be protected from cold? 1. Because they consume very much less honey, often not more than one-half; 2. Because, if they consume less honey, and have less cold to overcome, they will live much longer, and will be stronger in the spring; 3. Because, if less honey is consumed, less moisture will be generated by the bees, to be gotten rid of in some way.

How can bees be protected from the cold? By placing them in cellars or special repositories, or by protecting them out of doors in clamps or by warm packing.

Why should bees be kept dry? 1. Because if the inside of a hive is damp, the combs and especially the pollen in the combs will mold; 2. Because, if left where it is very cold, the moisture may condense and freeze on the combs so as to starve the bees when there is plenty of honey in their hives; 3. Because, if moisture is allowed to accumulate inside a hive it is likely to be condensed on the combs, and to be absorbed by the honey, making it unfit food for bees, and often producing disease.

How can this moisture be disposed of, and the hives and combs kept dry?

By giving a large lower entrance as advised by Arthur C. Miller, Allen Latham, and others. By giving a smaller lower entrance and some upward ventilation, thus producing a draft through the hive, and carrying off the moisture given off by the bees. By a very small lower entrance and warm packing, and absorbing material around and above the bees that allows the moisture to pass through while it retains the heat.

Perhaps I should add to this that bees in cellars or special repositories should be kept at such a temperature that they will remain in a semi-torpid condition.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

Mr. A. B. Marchant, Jan. 15, p. 45, gives some splendid thoughts on knowing one's location. Beekeepers could, to a very great extent, profit by studying their location and its resources.

* * *

Mr. Geo. L. Emerson reports bees wintering poorly in the vicinity of Fullerton. In this locality they are in better condition than for the past two seasons; but what later developments will bring, owing to the freeze, is hard to tell.

* * *

I miss the writings of E. M. Gibson, of Jamul, Cal. Mr. Gibson writes me that he has sold out and is living in San Diego. There are others who might take his place, and help keep California in the rank it deserves before the beekeeper's world.

* * *

Referring to what you say, Dr. Miller, p. 40, Jan. 15, I am contending that bees lose time guarding the entrance when there is a good honey-flow on. At such a time you could take the lid off and leave it so for a week without doing any harm. The original discussion was over a colony that built up very rapidly in the spring with a very large entrance.

* * *

Almost immediately following the freeze we were treated to a fine rain. In some localities the downpour was heavy, and more than three inches fell—the heaviest being in the vicinity of Santa Barbara and Ventura. In this locality we received only one and one-fourth inches. However, it is sufficient to start the early spring flowers that give us an abundance of early pollen.

* * *

The first of the year I started to keep a record of the number of days during the year when the bees were able to find something to work on. By the end of the first week every thing was so badly frozen that I gave it up. The twenty colonies in my back yard have found pollen somewhere every day they could fly; but where they found it since the freeze I have not been able to learn.

* * *

Conditions are somewhat uncertain as to the damage to our honey-plants; but developments have reached a point where I feel safe in making some statements. The orange trees are frozen very badly in places, while in more favored localities the damage is much less. Where the trees are the worst frosted, the bloom will be materially de-

creased; but in the more favored places there seems to be no reason why there should be any shortage in bloom. If, perchance, the bloom should be reduced one-half, there would still be all our bees could handle. Some believe the button sage is killed. I did not share this opinion for a time; but after carefully examining it in several localities it seems almost certain that much of it is entirely destroyed so far as this year's bloom is concerned, though I believe we may see some bloom if we are favored with good rains from now on. The white variety is not injured, it being of a much more hardy type. It stands the cold of an altitude of more than six thousand feet. The eucalyptus, which is of so much value as a winter stimulant, is very badly frozen, and much of it will die. The peppers, grevalias, and acacias—in fact, every thing, is frozen; but the oranges seem at this date to have stood it better than most other trees.

* * *

A COLLAPSIBLE VEIL MOST DESIRABLE.

On page 810, Dec. 15, A. C. Miller discusses bee-veils at length, and finally decides on one that would not appeal to me for a minute. I would rather have one I can stick into my pocket, so I will not look like an old maid with a bird-cage, when going from place to place. Silk bobinet veiling, with the lower skirt of cheesecloth, makes a dandy. Put a shirr-string in the top to draw it around the hat crown; bring the skirt down on the shoulders, the slack around in front; then tuck it in your shirt-front. I have worked many a day in this way, and did not get stung. It would be torture to work all day with a coat on, such as is shown in the illustration. Mr. Miller also says, "But you will have a more pleasant time if you keep decent, good-natured bees, and dispense with a veil altogether, or almost." That was my idea when I came to California. I laughed at my uncle for wearing a veil so much; but he said, "Never mind; you will come to it." We started extracting. I was uncapping and throwing out, he taking off and wheeling in. Near 3 P. M. the old gentleman was getting tired, so I offered to change with him, which I did. Wheelbarrow and smoker in hand, I rushed out, and very promptly I rushed back, perfectly in love with a veil, and have been ever since. I do not care how gentle bees are, when you get them stirred up with good lively extracting operations there is going to be a good demand for a veil.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

RESULTS OF GOOD CROPS.

We are all acquainted with the results that follow the making of goods and profitable crops. We all know what an "invigorating" effect it has on us, how it livens us up, and spurs us on to do better things, and to greater interest in those things that concern us in our chosen pursuit.

These things are mentioned for the reason that the writer is looking forward to the time when beekeepers will get together more often, and take into consideration some of the most important matters that need immediate attention. It has been, and is yet, a hard matter to do very much in this direction during years that have not been profitable to the beekeeper. In the first place he has lost much of the interest in the business; and even if he has not, the fact of his being rather short of pocket money as a rule does not permit his going to any meetings that may be held to discuss these important matters. How different it is, though, when he can jingle the bright coin with which his pockets are heavy!

FAVORABLE PROSPECTS.

Although some portions of the great Lone Star State suffered somewhat severely the past season, other parts of it obtained very fair crops of honey, especially throughout the cotton belt. There was considerable cotton honey produced during the 1912 honey season, and this helped materially in bettering the final crop report for one of the poorest seasons that we have experienced for many years, taking the entire State as a whole.

It is gratifying indeed, however, that the bees are, almost universally, in excellent condition for next season, and wintering so well that they will be in fine order generally for the next season. Adding to these excellent conditions the prospects for a good honey season this year, the beekeepers are expecting some big harvests to make up for the losses, in some localities, the past two seasons.

The late fall and winter months have been bountiful in good soaking rains, and these have been pretty general all over this large State. This, followed by an early spring and a dry summer, interspersed with a few good rains, is what the beekeeper terms "a good thing for a big honey yield." Just how near we shall get to these ideal conditions, it is too early to tell now; but it is to be hoped that the present excellent conditions will continue and even improve. One of those "bumper crops" we used to

speak of in years gone by would put new life into the beekeepers; and such new life would show its effect in many ways, with the result that more interest would be taken to make beekeeping better than it has been the last few years.

* * *

BEE INSPECTION IMPORTANT.

One important matter concerning the beekeepers, not only of Texas, but all States and countries, is that of careful, systematic, and effective inspection of apiaries for diseases of bees. The time has come when we must be exceedingly careful about such a thing as running the risk of getting foul brood or any other contagious diseases into our apiaries. In this case an ounce of prevention is better than a pound of cure.

The next question then is, how we can best arrive at methods and means for taking the proper steps to accomplish results that will give us proper protection.

Just such questions as this should be taken up at various gatherings of beekeepers all over Texas at the present moment. And not only is this of exceeding importance in localities where bee diseases already exist, but just as important where they are not already present. The one idea in the mind of every beekeeper should be to keep it away, and not wait until it has appeared in the neighborhood. We shall not attempt to say how far away we should keep it; but every beekeeper knows that the further such dangerous diseases are kept away the better.

It is hoped, therefore, that the beekeepers in every State will get together and consider what may best be done to evade any of these dreaded troubles altogether, or to get rid of them after they have come into a neighborhood.

It should be remembered that Texas has a State foul-brood inspector in the person of the State Entomologist, at College Station. There is no doubt about his doing what is proper in dealing with such matters, and looking after the welfare of the beekeepers of Texas. But it should be also remembered that it is up to the beekeepers to lend him all the assistance in their power, and to aid in procuring the necessary funds with which the work is to be done. And it is also the duty of beekeepers of this State to see whether or not these duties are performed properly and to the best advantage for the beekeepers. They have a right to expect this in return for the efforts that may be made by them.

Conversations with Doolittle

At Borodino, New York.

LOOK AFTER THE COMBS.

"Last fall I had many colonies weak in bees, so I doubled them up until I thought all were strong enough for winter. How can I best preserve these combs till I wish them for use again? Would new comb be preferable to the old, no matter how good and straight the old combs are?"

It is best to keep a careful lookout for every bit of wax in the shape of burr-combs and brace-combs, and all scrapings of honey-boards, frames, and hives. All combs which are crooked, or which have been damaged through breakage or from mice, should be rendered into wax. When saving out these pieces, it should be borne in mind that the *choice* comb is so valuable that its destruction shouldn't be entered upon hastily.

In order to determine the worth of nice straight worker combs, it is well to remember that many experienced beekeepers think it very profitable to purchase full sheets of comb foundation at the rate of ten cents per frame. This, added to the cost of transportation, and the time required to wire and fasten the foundation in the frames, would make the cost of a frame filled at least 13 cents. The same frame filled with a good worker comb is certainly worth as much, and in my opinion more. The wax that can be gotten from it would hardly bring 6 cents, and this must still be discounted on account of the labor involved by way of rendering and cleaning the wax. My conclusion is that combs in an eight-frame Langstroth hive are worth at least 50 cents more for use as combs than they are for the purpose of wax. To my mind it is worth while to know (when one has frames of nice worker comb which can not presently be made use of by the bees) how to keep them in a good state of preservation. Mice and the larvæ of the wax-moth are the enemies that work the most destruction where the combs are kept in a warm dry place; and if kept cold and damp, the mold and soured pollen come in as deteriorating influences. To guard against the deterioration or destruction of combs, I have experimented quite largely, and recommend the following:

If one has a bee-cellar that is mouse-proof, and cool and dry, the hives of comb can be set therein with every assurance that they will keep well. But any warm damp cellar is to be avoided, lest the combs become moldy with soured pollen. It appears that a somewhat high temperature is necessary for the propagation of wax-moths, for I have never known them to breed in

combs placed in a cellar that is fit for them to occupy; and therefore I feel it safe to say that any good cool dry cellar would be a sure protection against the moths; and if such a cellar is not already mouse-proof it can be made so without any great amount of work. By placing hives of combs over strong colonies of bees as soon as the warm season opens, so that the bees can have free access to them, neither mice nor moths will be able to touch them. From one to six hives of empty combs can be given to good colonies. Precaution only need be taken that no more hives be given than the bees will go through in sufficient number to go over all the combs. When any one can use strong colonies for this purpose, it is the safest and best method; for the bees not only protect the combs completely, but also clean them to a very great extent, so that they are put in better condition for preservation by other methods. It is not practical to store combs over colonies when working for comb honey. In such a case the combs would have to be removed at the beginning of the honey-flow, else no good section honey could be obtained. But where working for extracted honey, they can be used, or the filled or partly filled combs reserved for feeding purposes for either fall or spring.

But the way I have used the most of them, and which has pleased me the best, and a way which has proven entirely effective against the moths, is to hang my combs up to the light and air with a space of from 1½ to 2 inches between each comb and its neighbor. Especially is this the best way for all combs which have had brood reared in them till they have become toughened by the cocoons accumulating from many generations of brood. Such combs are most freely used by the moths. If the combs are new, and of clean white wax, the light seems to have a deteriorating effect upon them, causing them to become brittle, and to break or crumble when handled, though the bees seem to use them as well as ever during hot weather. Knowing how well combs keep when stored in this way, and for practical convenience in following this plan, racks to support them were made in my shop overhead. These were placed so as to admit freely the top-bars of my frames. Windows were placed conveniently for light and air; and by using screens, neither bees nor millers could have access to these combs. These racks, being so far from the floor or any other accessible place for mice, afford an ideal place for keeping all combs not in use.

General Correspondence

SHALL WE ENCOURAGE MORE TO KEEP BEES?
OR SHALL WE RENDER MORE HELP TO
THOSE ALREADY IN THE BUSINESS?

BY J. L. BYER

The December issue of the *Canadian Bee Journal* reprints an article contributed to the *Farmer's Advocate* by our well-known friend R. F. Holtermann. The editor of the latter paper asked for a summary of the prospects of beekeeping in Canada, and the article in question deals largely with that phase of the industry; and while the views expressed may not be in harmony with the ideas of all others engaged in the business, they are, nevertheless, very interesting, and worthy of our sincere consideration. After commenting on the fact that European and American foul brood are a serious menace to successful beekeeping, he says, "Just now, it seems to me, to advise men either in Ontario or Quebec to go into beekeeping is like advising a man to go into hog-production with an outbreak of hog cholera in the vicinity, only far worse." Referring to the claim that these diseases are not checked more effectually than is the case, because of lack of funds from the Province to fight them properly, he further says: "I shall let the public judge as to the wisdom of such a policy, and whether it is wise to seek to develop, at expense, the industry on the one hand, and allow those already in it to be wiped out on the other for lack of funds."

The editor of the *Canadian Bee Journal*, commenting favorably on Mr. Holtermann's article, says, among other things, "Our officials are not to blame. On the contrary, they fully recognize the impossibility of checking the scourge with the scanty means placed at their disposal by the Government. If, however, the *whole* of the funds now being spent for apicultural purposes in the province could be used for taking vigorous repressive measures against bee diseases, better results would ensue."

Let me digress just here to state that European foul brood is the disease that Mr. Holtermann has mostly in view, and I presume the editor of the *Canadian Bee Journal* also refers particularly to this brand of foul brood, as it is generally admitted that the old-time variety we have been so familiar with is gradually being cornered, and has lost its terrors for most beekeepers.

Returning again to the article in question, let me say that I have quoted from it, because in reading it one can not help seeing at once that the author believes it is a

fallacy to try to persuade others to go into the business of beekeeping when those already in the business are up against such a serious menace as foul brood. And right here let me add that, during the past season, when traveling, meeting in convention, or in other ways associating with the majority of our producers, I found by actual inquiry that nearly all are of the same opinion as our friend in this matter. Ever since the Provincial apiarist has been appointed, I have been a loyal supporter of him, and to-day I believe we have a man in the position whom we have reason to be proud of; but at the same time there is no use in denying the fact that the work being done in connection with apiculture, in so far as practical help to those in the business is concerned, is not what most beekeepers were expecting when the government decided to open a department of apiculture at the Agricultural College. No doubt the same opinion is held by many beekeepers in the different States that have departments of apiculture; but as I am not so well acquainted with the producers so concerned, I can not speak with authority for them. When the editor of the *Canadian Bee Journal* says that if the *whole* of the funds now being spent for apiculture were applied to foul-brood suppression, I do not think he means to imply that the department should be abolished, but, rather, that as much as is now being granted for *all* the work should be given for foul-brood suppression alone.

I have already referred to the fact that the majority of the beekeepers believe that less encouragement should be given to those contemplating going into the business, and that more help should be given to those already established. This being a fact, it may be asked why more has not been said about it in a public manner; and for answer I would say that rather short crops, with an unlimited market for the same, has caused honey to reach a high-water mark here in Ontario, so that any real "kicking" is almost an impossibility at present. But let the present "boom" end, a series of heavy crops follow with attendant lower prices, then surely there would be a "howl" against any systematic propaganda for developing *more* beekeepers.

To those who have read thus far, this will no doubt seem but a bit of carping criticism; but I wish to assure one and all that nothing is further from my mind; for, regardless of what any of us beekeepers think about the matter, so long as our Govern-

ment fosters any industry in agricultural colleges, or in any other way, so long we may expect to see systematic instruction given in that industry; and all who will are at liberty to take advantage of that instruction. At the same time, care should be taken not to exaggerate the possibilities of the calling as an income-getter, and especially should all be warned of the very serious problems confronting the would-be beekeeper; for when all is said and done, even the most enthusiastic beekeeper must admit that our business is one peculiarly fraught with dangers, and often unexpected difficulties, all out of proportion to any other rural industry.

Again, let us remember that, in this matter of giving encouragement to beginners, the Government or its officials are not the chief sinners by any means. Without any desire to try to resolve ourselves into a mutual-admiration society, I would ask the question, "Are not beekeepers as a class the most unselfish lot of mortals that ever existed?" Do you ever feel like "turning down" some eager (perhaps needy) young fellow when he comes asking, in all earnestness, something about your business—the business you love? If you are feeling a bit out of sorts when you start to answer these questions, perhaps you may try to squirm out of them by saying, "What other business men are inclined to tell the secrets of their business and ready to lend a helping hand to others?" The very fact that you thus hesitate in answering, proves the truth of my first question. After all is said and done, *that very trait* in the make-up of most beekeepers has been the means of my getting so much enjoyment out of life during the past few years that we have been making our living from the bees alone. Of course, there are some *few*, even among beekeepers, who are as "business-like" as lots of people in other professions; and they will refuse to tell any thing about their methods, and will treat almost with contempt any one who would be so foolish as to ask for help. If you are not one of that class (and I don't believe you are), in all honesty how do you like to rub shoulders with such men when at conventions or other places? And, by the way, very few, like the ones described, ever come to conventions or attempt to mingle with the beekeepers at large.

Yes, life consists of more than *business*; and while self-preservation is, we are told, the first law of nature, yet none of us liveth to himself; and, generally speaking, all we can do for the other fellow will return us good interest—if not in dollars, in some-

thing worth much more than can be estimated by the currency of our land.

Mount Joy, Dec. 29.

[Deeming it no more than fair to let Mr. Pettit make his own comment on the above, we submitted to him as well as to Mr. Byer a proof. Mr. Pettit says:]

I don't know that there is very much to say, as Mr. Byer has answered himself pretty well before he has finished; but it does look to me like setting up straw men for the fun of knocking them down. First, the implication is made that I am inviting people to go into beekeeping instead of helping those who are already engaged in the business. In reply, let me say that I have been repeatedly asked by my chief to prepare a bulletin especially for beginners in beekeeping, but so far have not had time to do so. My work has been fully occupied in an educational campaign, principally for those already engaged in beekeeping, and more particularly for the benefit of those who have or expect in the near future to have foul brood to contend with. I can say, without fear of contradiction by those who know the facts of the case, that 19 out of 20 of those receiving benefit from the expenditure of government money for beekeeping in Ontario were already engaged in keeping bees before this department was established. The whole trend of educational work is along the line of making them better able to contend with foul brood.

Surely Mr. Byer is joking when he speaks of the advancing prices of honey as a "boom." It is not keeping pace with other food products, and there is no indication of their prices being reduced in the near future.

Mr. Byer makes the statement that during the past season, "when traveling, meeting in convention, or in other ways associating with the majority of our producers," he found by actual inquiry that nearly all are of the same opinion as our friend in this matter. Now, there are 10,000 beekeepers in Ontario, and I imagine I am safe in saying that at least half of them are producers of honey; but supposing only one in five were a producer, Mr. Byer was not on government work of any kind except to attend two or three demonstrations in one county, and at the Toronto convention in November. How, then, did he come in contact with 2,000 Ontario beekeepers, and have the opportunity of questioning each one as to his opinion of the work done by the Ontario Agricultural College in order to find that the majority of them thought as he does in

the case? As a matter of fact I receive a number of kind letters of appreciation from Ontario honey-producers, but very few indeed of the nature of Mr. Byer's letter.

[We hardly think that Mr. Byer meant that he had actually questioned over half of the producers. By "majority" he probably had in mind those more prominent in the industry. See editorial.—ED.]

HOW A BREEDER SELECTS A GOOD QUEEN

BY H. G. QURIN

In a recent issue of GLEANINGS I note that some of the breeders are asked to tell how to judge a queen. In judging a queen, a breeder is often governed by principles difficult to express in words. A queen in a cage can not very well be judged, as all one has to go by is her looks; and one can tell no more about a queen from her looks than how far a toad will hop from its looks. It is true we can tell where the queen is of good size, and is properly proportioned; also whether she is spry and active, and we can make a good guess as to whether she is laying or not; but for any thing outside of this we must go to the hive where she is doing such duties as are required of her, and where the qualities to be desired in a queen are in evidence. If I were selecting queens for my own use I would not ask to see the queen at all, but would judge her by her colony.

In selecting a breeder, we naturally have to select a queen whose progeny possess such markings and qualities as are designated by Mr. Purchaser. Such breeders are almost always selected from queens at least a year old, as otherwise we can tell but little about their working quality. However, prolificness, gentleness, and ordinary working quality can be foretold in queens much younger than this. There probably is no one quality that pleases the masses more than an extraordinarily prolific queen; and as a rule it is these populous colonies which roll up the most surplus.

One thing about the size of a queen. The larger the queen, the more pleased is the customer; yet this larger size does not necessarily mean that the queen's prolificness is in accordance with her size. In fact, it often happens to be just the contrary. I call to mind instances in years gone by when, in coming across an extra-strong colony, I would invariably spot them as breeders, providing the bees possessed the required qualities. However, just as often as not when I looked for the queen I found her to be a rather undersized individual, and there-

fore she would be rejected as a breeder. I have since often thought that I would at some time try such a queen as a breeder for at least a few batches of cells, for it is my opinion their daughters would be good and of good size. My theory is that the bees, however, from such queens are not as long-lived as those of a normal-sized breeder.

The following are desirable points in a breeder: Solid combs of brood, not too early laying in the spring (real early brood-rearing often causes spring dwindling), and a breeder whose bees are reasonably gentle (not as harmless as flies), but just reasonably docile bees which will cap honey white, and fill the boxes out plump, even if the flow is a little light. Then, of course, we want bees that swarm as little as possible.

Some bees, when a honey-flow slackens, stop work in the boxes and crowd the queen into the brood-nest. This kind of bee has never suited me. While I admit it is nature to be looking out for herself, I prefer to have the sections completed at the expense of the brood-nest, even though I have to furnish the bees their winter stores.

Bellevue, O.

THE ADVANTAGES IN FAVOR OF A SHELTERED LOCALITY

BY DAVID ROBERTS

The apiary, when convenient, should be located in a place protected from prevailing winds. My home apiary, for a reason that does not matter here, is in two divisions—one on a southward slope sheltered on the west by tall trees, and on the north by buildings; the other, in a young orchard exposed to the northeast and south.

I consider the season of 1911-'12 a good one in which to make a comparison between these divisions. The winter before, I prepared all colonies alike, using on top of the honey-boards cushions 6 inches thick, of forest leaves. Leaves of the previous year are more crumbly than those of the current, and make fair packing if well compressed and kept dry. The entrance-guards were open $6 \times \frac{1}{4}$, veneered by narrow strips of tin, and nailed to the hives to keep off mice. This was done in November, and I did not see the bees again until early in March, when I noticed that in the open, on account of freer circulation of air, the warmer molecules in close contact with the bees, because of being lighter, gave place to cooler ones, and were carried away from the hive. This was a direct loss of heat, but at a time when the bees could stand it best. As a result, the loss here was more immediate. In the

shelter, more moisture remained in the packing, and in freezing gave back some of its heat. Up to this time it caused no trouble. But when this mass began to thaw it proved worse than worthless, for it called back all of the heat it had given up, and at a time when the bees could least afford it. This condition, however, could have been avoided if attention to the packing had been given before now. As it was, it turned the scale for the time in favor of the exposed division. But, wait a while.

Later on, the sheltered division gave a good account of itself. It proved that "location" is a factor in beekeeping in more senses than one. After all, it is not so much a question how many colonies survive the winter, but, rather, what progress the survivors are making in early spring. It is the bees at the day of harvest that count.

"Bees in the shelter are more prone to swarm." If this assertion were true, and no swarms were desired, this would seem to throw the advantage again in favor of the exposed. But shelter is not conducive to swarming except so far as it favors brood-rearing. Give more time to the exposed colony, and manage it the same otherwise, and it will usually swarm. "Time is money." Especially is this true with the beekeeper, for here lies the difference between a crop of honey and no crop at all.

I say, keep in the shelter and use more packing.

BEES DO NOT LOSE THEIR STINGS WHEN ATTACKING OTHER BEES

BY ELIAS FOX

In thirty years of practical experience with bees, during which time I have seen a good many queens and thousands of workers killed by being stung, I have yet to see the first bee with a sting lodged in it. I have seen thousands of them administering the sting, but never yet saw one lose its sting. They do the work very quickly, and are immediately ready for another or perhaps a dozen more victims. This, it seems to me, is a wise provision of nature, that they may protect their homes against intruders and robbers; for if it were not so, a colony would be nearly defenseless. On the other hand, it is a wise provision of nature that they lose their stings when using them on their keepers and animals, as a warning to be more discreet in their application.

If you think the pain is less severe when the sting is not retained in the flesh, some

time next summer on some hot day while you are bending over a hive let a bee sting you on the back just between the shoulders. You will straighten up so quickly that the sting will be instantaneously withdrawn by the shirt; and if you don't say it is as painful a sting as you ever received I am no judge of pain.

As for drones, I don't know, as I never yet have seen a bee sting one, although I have seen them make all the motions, and act as if they wanted to sting them; yet I think it is very evident that they do sting them—at least I know they can cover the ground in front of the entrance with dead drones over night when the honey-flow is brought to an abrupt end. But I never yet have seen a sting left in one, neither do I believe they lose their stings when killing drones any more than when they kill a worker or queen. If they did it would be a queer provision of a wise Creator, as it is just as essential to the welfare of the colony that they rid themselves of the useless drones after the honey-flow ceases as it is to rear them so carefully before the flow.

The queen's sting is a little different in shape from that of the worker, being slightly curved, and apparently smooth, and free from barbs, similar to that of a yellowjacket or wasp that can sting every time occasion calls for it. I should like to ask if any one has ever been stung by a queen bee.

Out of curiosity I have tried every conceivable manner, both with virgins and old laying queens, to have them sting my hands and arms, and have never yet been able to have that curiosity satisfied; and if any one else has, I am from Missouri.

VEILS.

I was amused to read Arthur C. Miller's article, Dec. 15, p. 808, relative to the various veils. To me there is more real merit in the last two lines than all the rest of it. His pet veil, I see, has the same petticoat that he was making fun of. I have tried the most of them he has described, in a less exaggerated form, and the very best one I have found is the good black net with black net silk and all, with a good rubber cord in each end, one of which fits tightly around a hat of any kind, and the other around the neck. It can be adjusted or removed almost in a second; is always ready, and can be carried in the vest pocket if desired, with no danger of receiving stings through it. I feel just as safe in one of these among the bees as I would in my house with doors and windows screened. I would not give *one* for a dozen of any other kind I have ever seen or read of.

Union Center, Wis., Dec. 27.

The thimbleberry in bloom.—*Photo by Wesley Foster.*

THE FLOWERS OF THE FOOTHILLS

BY WESLEY FOSTER

The love for and knowledge of the flowers in a way measures the quality of the beekeeper. If he has not an intimate acquaintance with the honey flora in his neighboring fields, hills, and ravines he will be handicapped as a successful beeman.

Let us go for a walk on an early May morning. Before we have gone more than half a mile up the slope toward the foothills we stop and listen to the hum of the bees passing over our heads back and forth from the apiaries in the valley to the hawthorn, chokecherry, and thimbleberry bloom in the foothills.

We find the chokecherries and the hawthorn lining the streams issuing from every ravine and canyon. The hawthorn is so fragrant that the aroma is sickening, and the bees swarm over the shrub-like trees in thousands. It is a merry trade that is kept up; and all the bees have to do is to glide downhill for the matter of a mile or so to get home with their load of hawthorn honey. A hive of bees has filled a super of comb honey from the wild-flower bloom before the 10th of May, though this is uncommon. The great benefit of this early bloom is to build up the colonies in numbers for

the alfalfa and sweet-clover flow in June, July, and August.

The thimbleberry is a beautiful shrub, fit for any park or lawn; and I'll wager that the nurserymen sell a good many of them for that purpose too. They are easily obtained, for there is scarcely a boulder where a thimbleberry-bush is not growing beside it, throwing its branches laden with bloom over the edges of the rock in a very pleasing and artistic way.

The thimbleberry has a large white flower an inch and a half to two inches in diameter. The center is yellow, and the bees wallow around in the pollen, getting all covered with it. The berry, when ripe, is about the size of a red raspberry, and nearly the color, though not so brightly colored. It is not so edible, though when we are out for a picnic we eat them and call them good, probably because they grow wild and are plentiful. They are mostly seeds, with but very little juice to furnish a taste. Perhaps Mr. Burbank or some other plant-wizard could develop something worthy from the plant. A patch of thimbleberries would certainly be a delight to the eye.

But we are out in search of flowers, and here we come to a flower-covered slope of the mountain covered with wild sweet williams. (See cover picture.) This is not a hon-

Daisies from which the bees get pollen.—*Photo by Wesley Foster.*

ey-producing flower, though it is a most fragrant one. A few bees have been seen on the blossoms, and hovering over the fragrant clusters. Probably the sweet perfume attracts the bees, and they fly around till they find out there is little if any thing there for them. Does each bee, when she goes out to work in the fields, have to learn the blossoms that furnish honey? It is reasonable to suppose that the bee has to learn some things, and not depend on instinct for every thing. From the sweetness of the wild sweet-williams I should guess that many a bee has conducted a fruitless search for nectar among the pink and reddish blossoms of this delicate flower till she learned that 'tis not all nectar that smelleth sweet.

As we return from our walk we stroll through an old orchard, and here under one of the trees is a dainty little bed of daisies. The bees are busily at work collecting the pollen. None seem to be getting any nectar, so we decide that this daisy, at least, is not a honey-producer. The variety we do not know; but it is one of the small kinds with a yellow center and white petals. The stems hold the blossoms about six inches above the ground, and they grow close together in little groups as so many flowers do, for the flowers are social in their habits as well as the bees.

In our walk we have seen many flowers of brilliant hue, but with no odor that attracts the bees, and these we admired for their own sake. The flowers the bees love are the ones that appeal to us as beemen; and as we reached home we remarked that alfalfa is making a good start, and sweet clover is becoming evident along the roadsides and ditch-banks.

Boulder, Col.

PROTECTING ROWS OF HIVES IN UTAH

BY M. A. GILL

Although I am hardly a beginner in the bee business, yet I am a beginner in giving better winter protection in this western country, so am sending some pictures showing how I prepare for winter by a plan which proved so successful during last winter.

Fig. 1 shows the front of two rows two hives high, and the backing of forest leaves between (myself in front). The covers have been removed from the bottom rows, and the entrances are contracted to $\frac{3}{8} \times 3$ inches by a lath with a notch in it tacked on the entrance. The covers on the top row have an air-space to allow moisture to escape. Fig. 2 shows the back or north side, show-

FIG. 1.—M. A. Gill's method of protecting a whole row of hives.

ing the tar-felt paper coming down nearly to the ground. The space below, and, in fact, half way up the back side, should be well banked up with earth. Forest leaves, alfalfa straw, or seed chaff, as it is called, I think the best of packing.

While this kind of packing would not do for Wisconsin or Canada, I think it ample for our western States, as it keeps the bees absolutely free from outside moisture, helps to conserve their natural heat, and is entirely impervious to the prevailing winds, which are so detrimental where a continual blast is against the hives. The loss of bees by mixing up is much less than one would suppose during the days when they can fly.

Hyrum, Utah, Dec. 16.

MY PERFECT FEEDER

BY JAY SMITH

There is no one phase of beekeeping that I have studied more carefully than the question of feeding and feeders. In my earlier experience I tried various feeders, every kind that seemed to have merit, and found them wanting in one point or another. This lesson, however, I learned: Colonies properly fed always outstrip the others. But it was a big job to feed 100 colonies, as I am engaged in school work, and could not spare the time when the bees needed me most. So I joined that large of army of beekeepers who say that if bees have plenty of stores they will do just as well without

FIG. 2.—The back of the row shown in Fig. 1.

Filling the "Perfect" feeders.

feeding. The four years following ran something like this: Bees in large hives with plenty of stores did well; but about one-half did not have plenty of stores.

Perhaps one swarmed, and both the swarm and the old colony went into winter quarters a little short of stores. Both failed to respond to the call of the maple blossoms in spring. Perhaps the increase that was made depended upon that "fall flow" that did not come. Perhaps there was a failing queen. Yes, there are many "perhaps" in an apiary of but 100 colonies. So, after toying with the non-feeding method it was plain that, whether I liked feeding or not, I would *have* to feed if I stayed in the bee business.

Of all the feeders on the market, the Alexander was plainly head and shoulders **above** all others; but for me it had several **draw-backs**. I wanted a feeder that was always on the hive, so that, if necessary, I could **make** syrup and feed the whole apiary any time the bees needed it, and do it after or before school. The Alexander feeder is hard to fit to a hive. Where brood-frames are flush with the hive-bottom the frames rest on the feeder, shutting off the passage for bees, and killing them when handling frames, as the cross-piece on the back of

the bottom-board also comes in contact with the brood-frames. Then if not left on the hive the year round, in case the bees need feeding in the spring it takes more time to put the feeders on than I can spare.

After considerable experimenting I hit upon the feeder illustrated. I had the narrow cleats made at a planing-mill, and the material complete cost 5 cts. per hive. It took about 40 minutes' work per hive to make them. To fit the cleats I put ten of them in a vise so they could not split; then with a little drill I made the holes for the nails. They could then be nailed to the bottom-board without splitting.

There is a quarter-inch space between them and at the ends, for the syrup to run around. The lower side of the five cleats next to the door are notched so as to allow the syrup to run through, and the block on the back of the bottom-board is also notched so the syrup will run into the feeder. The syrup also stands in this, so you can see at a glance how much there is in the feeder. If it should become sour for any reason, all you have to do is to raise up the front end of the hive, and it will run out the door. The upper part of the lid is notched out so as not to crush bees if any should crawl out while the syrup is being put in; and there

Jay Smith's "Perfect" feeder in the rear of the bottom-board.

is a bee-space over the feeder so no bees are crushed when frames are handled.

This feeder is *always* ready. I have frequently fed 100 colonies in less than 15 minutes. The feeder holds one quart; so if it is desirable to feed for winter, feed them twice a day for four or five days, and they will be "choke full." I have 100 fitted in this way, and I see nothing lacking; and so I call it the "Perfect" feeder. The bees keep it glued up water-tight, and they like to cluster down among the cleats.

Mr. Aspinwall certainly discovered an important principle in making his hives full of little cleats. I helped hive a swarm in one of his hives, and I was impressed by the way the bees took to the cleats, spreading among them as naturally as though they themselves had made it. In this same manner do they cluster in my Perfect feeder when it is empty.

I do not believe beekeepers as a rule are alive to the importance of stimulative feeding. If you have good vigorous queens, large hives, and if you give a little warm syrup each night for a month before the honey-flow you will get a crop where others will not; and, what is more, your bees will go into winter quarters rich in stores where others will starve. Enough emphasis can not be laid upon the fact that *strong* colonies get the surplus where those not so strong will starve.

Some readers of GLEANINGS may remember that, several years ago, I wrote that the common eight-frame hive is entirely too small for a good queen. It was not uncommon for a poor queen to get more honey than a good one. The good queen filled the brood-nest and swarmed, while the poorer one did not swarm, thereby producing more honey.

For about six years I have used a Danzenbaker hive and extracting-super for a brood-nest (it is gratifying to me to see the trend is toward a larger hive). This hive is

good; but there is valuable space lost in cold weather, as the bees must keep warm a top-bar, a bottom-bar, a bee-space, etc., right in the cluster, while they might better be raising brood there, so I prefer a one-story large hive for extracted honey. The Jumbo hive is none too large. Bees will build up better in the spring, as they work better on a single large comb than on

smaller ones. Doubtless many readers have seen bees stick to one comb, filling it clear out to the ends before jumping to the comb above. There is a great loss of heat in this way where divisible hives are used; as, in order to preserve their heat to the fullest extent, the bees should rear brood in a circle, and this they will do only on large deep brood-frames. Seldom indeed do you see a man who has used large hives go to smaller ones; but it frequently works the other way.

If you are in a poor locality, use the Jumbo hive or one as large; practice stimulative feeding with the Perfect feeder, or one similar, and you will get honey when others lose their bees through starvation.

Vincennes, Ind.

[If we understand our correspondent he would call the Jumbo frame ideal if the empty cells above the brood were filled with syrup before the honey-flow to prevent the bees from storing the first honey there instead of in the supers. There is some danger of having a part of the sugar syrup carried up into the supers if the feeding is continued too late.

The feeder described is similar in principle to the Cary-feeder bottom-board formerly sold by supply dealers, although, in the latter, as is seen in the engraving reproduced herewith, grooves were cut in the rear floor board to make room for the syrup.—Ed.]

EXPERIENCES OF A FOUL-BROOD INSPECTOR

Eradicating the Disease Not Difficult if the Bee-keepers Co-operate

BY J. E. CRANE

Continued from page 86, Feb. 1.

The more I have seen of foul brood, and especially of the European type, the more fully I am satisfied that, in order to make a success of inspection, the work must be done in the most thorough manner. It is not enough when a case of foul brood is found to clean that up and go on one's way feeling that his whole duty is done. Unless every yard in that section is found and inspected, the work is likely to be of no permanent value; for if there should happen to be a yard just over the hill or across the fields half a mile away, where disease exists, it will soon break out again, and no lasting cure will be effected, and perhaps the cause will be attributed to the method of treating the disease. Of course, an inspector can not find *every* colony of wild bees, so we must watch with great care until we feel sure that every wild colony has gone out of existence. We shall then have the matter in our own hands.

As yet, there are few States that are willing to appropriate a sum large enough to do all the work that should be done as it ought to be done; nor have we enough inspectors to do the work. But I believe it would be better to do thorough work than to extend it over too large a territory and thus spread it so thin that, almost as soon as the inspector is gone, the disease will spring up.

It may often happen that a single yard is all that is affected in one locality, while in others it is scattered over a whole town, and in one case over almost one entire county.

There are some serious problems connected with these diseases. Already some States have forbidden the importation of colonies into their borders unless accompanied by a certificate that each colony is free from disease. This is already causing some trouble. How about the time when various States will prohibit the importation of honey from diseased apiaries? And why should they not do so? Honey is consumed in our larger towns, and the containers are thrown on the dump to scatter disease if there was any in the honey used.

The ignorance of a great many beekeepers enters into the problem of how to get rid of disease. Many have never heard of such a thing. I have visited several beekeepers; and as we have opened hive after

The Spencer boys, who are expert at extracting fish from the lake and honey from the combs.

hive, and have found only webs and cocoons and filth, the moths have received the exeration of the owners, as they have no conception of disease.

BOYS THAT KNOW HOW TO WORK.

It is no easy job to clean up a large yard where foul brood has a strong foothold. In one such yard I found the owner at work. Hearing a noise in his honey-house I went in there and found his two sons, one eleven and the other thirteen, dressed in overalls. One was uncapping, the other turning the extractor. Both were working like old men. I send their photos as worthy of a place in GLEANINGS. They live near a lake, and it seems evident that they can extract fish from its waters as well as honey from the comb.

One beekeeper to whom I wrote, asking if he had had any experience with disease among his bees, replied that he had lost about half of them during the winter, and what he had left were quite weak; but he thought that there was no disease among them. I improved my first opportunity to visit him, and found that most of the colonies that remained were more or less diseased. While I talked bees with him, his good wife talked to me on the subject of religion, for she was anxious to know if I was prepared for "the solemn hour of death." I was somewhat embarrassed. I didn't quite know what to say. I thought I was in some measure prepared to live, which seemed to me to be of much greater importance. Of course, she meant well, good soul that she was, and it is an awful thing to think of one's going through life at odds with the Almighty, caring nothing for him when we may live with him on terms of

friendship and filial affection, and even sweet companionship. When our lives are properly adjusted to all above and around us it is a glad and joyous thing to live, and there need be little fear of death.

But the inspector has little time to discuss religion or politics if he would do his duty. His life is a busy one, and he takes an interest in it that few public officials surpass, for the enemy he fights is a personal one, and unless it is overcome and destroyed he knows not how soon it may reach him and greatly injure his own business.

THE UNPLEASANT PART OF THE WORK.

While there are many pleasant things about inspection work, it is by no means all pleasant. There are some long days and long delays waiting for trains. If prepared for work, one must dress rather plainly, for good clothes are almost sure to be ruined. I prefer to go dressed for work so as to accomplish the most in the least time. Al-

One of Mr. Holtermann's students securing full sheets of foundation by means of melted wax in a "bulb" wax-tube.

though last summer was quite dry I was caught in two showers, and was wet to the skin. One day I started to visit a yard that I was told was two miles away, and found it at least four miles, and over a tremendous hill. Just as I reached the place a thunder shower overtook me, and I had to turn around and start back without opening a hive, as I had to take a train that afternoon. A deer, as though to make me ashamed of myself for getting wet, came out of a pasture, and, walking near me, watched me with its curious soft eyes, then ran ahead, crossed the road, and went into the forest on the other side.

After reaching the hotel and station I had time, while waiting for the train, to glance through a butter-factory where they sometimes make 5000 lbs. of butter in a day.

BOTH DISEASES IN ONE HIVE.

I notice there has been some question as to whether American foul brood and European foul brood are ever found in the same hive. I have found but a comparatively small amount of American foul brood; but where I have found both kinds in proximity, I have been quite sure to find some of both kinds in the same hives.

Middlebury, Vermont.

A BULB WAX-TUBE FOR FASTENING BROOD FOUNDATION IN FRAMES

BY R. F. HOLTERMANN

In my opinion it is wasteful to fasten comb foundation in brood-frames by means of a saw-cut in the top-bar. First, it weak-

Mr. R. F. Holtermann's four helpers for the season of 1912. Top row: Closson Scott, Newton Falls, Ohio, and C. J. Hawkes, London, England; lower row: D. Glenelg Holtermann, Brantford, Canada, and Felix B. Stump, Parkersburg, West Virginia.

Atwater's home-made wax-press.

ens the bar. The frame I use has a top-bar $1\frac{1}{8}$ wide by $\frac{5}{8}$ deep, and no saw-cut. There are nearly 10,000 extracting-frames in use, and only once in a very long while, when the wood is cross-grained, can a sagging top-bar be found. This top-bar gives me one row of cells to each frame more than the $\frac{7}{8}$ top-bar. Next, I get the use of one more cell of comb foundation to each sheet, which, in 1000 frames, is quite an item.

The illustration shows our method of putting in brood foundation. Upon a long board are put three smaller boards that just slip inside the Langstroth frame, and are of a thickness that, when the frame is slipped over this smaller board, a sheet of foundation upon this smaller board rests on its upper edge against the center of the top-bar.

A rubber bulb and glass tube is used to take up the melted resinous wax (by guess one-third resin and two-thirds wax), and this tube is run along the top-bar to fasten the foundation as shown in the illustration. The under board is moistened by means of a sponge to keep melted wax on the sheet from sticking.

Brantford, Canada.

VARIOUS METHODS OF TREATING AMERICAN FOUL BROOD

Rendering Wax Economically from Old Combs

BY E. F. ATWATER

The beekeeper who produces extracted honey in a foul-broody locality need not abandon its production for that of comb honey. Some very extensive producers of extracted honey are continually confronted with the disease, largely as a result of the carelessness or ignorance of the small beekeepers and box-hive men near by. One man of my acquaintance even thinks it is easier to control the disease when producing extracted honey than when producing comb honey.

In the line of equipment one needs always an ample supply of extra hives, frames, and foundation, to cope with any emergency; a bee-tight room, a steam-boiler not too small; two powerful wax-presses as shown in the illustration, and a few barrels or galvanized tanks. The bees must be examined in early spring; and any that are badly diseased should be sulphured, and the hives securely closed and stored where no bees can enter. Colonies having but little disease must have the entrances contracted

to $\frac{3}{8} \times \frac{1}{2}$ or smaller; and if but few diseased colonies are found they should be hauled home that evening where they can be treated more safely than at any outyard. A later examination will show if the disease is appearing in other colonies. If one or more foul colonies in your own or near-by yards have been robbed by your bees, a second examination may disclose a few more diseased colonies, or, as has happened twice in our experience, half or all of the yard may be found affected; and then the only recourse is to treat the entire apiary—not so colossal a task as might appear.

At the opening of the flow, every diseased colony must be shaken into a clean hive containing full sheets of foundation. Regardless of whether it is necessary to disinfect the hive, we wish to ask, "Where are we to store the combs better than in the hives from which they came? then, if not rendered until late in the season, how can we make sure that the destruction of all spores is complete in any better way than by boiling the hive after all combs are melted?" Aside from this, we are satisfied that it is not necessary to disinfect the hive. Mr. Trickey, of Nevada, recommends taking several combs away from each diseased colony a few days before shaking. This is not advisable if the flow is at hand, as the bees will fill the empty space with comb. But if not too large a proportion of colonies is affected, and the flow is at hand, so there is no robbing, it is well to take away several combs from each diseased colony, brushing the bees into the hive. To be sure of results, the queen should be caged—preferably in the morning. When evening comes, a new hive of foundation should be set in place of the old one, the lid taken off, and the bees clustered on it, and dumped in front of the new hive. Then the bees should be taken from the remaining three combs, the queen liberated, when the cure will be complete. Taking away part of the combs causes the bees to cluster and to start the secretion of wax, and very greatly reduces the actual work of shaking. This shaking should be started when the bees cease flying for the day, and should be continued until dark.

In our own work we now use and prefer the Chantry method of cure, where the yard can be revisited in from three to five days. In this plan the new hive is filled with frames containing full sheets of foundation, except that the central frame is at least one-fourth to one-half full of empty comb (the poorest combs in the yard may be so used), while on each side of this frame is one frame with a starter only. Three to five

days after shaking, this central comb is carefully removed; and while the bees are working freely, the bees are carefully and quickly brushed in front of the hive or into it, and another frame with a full sheet of foundation is added. By the Chantry plan, any diseased honey not at once used for wax-working will be stored in the bit of old comb. The empty space on each side favors compact clustering and free wax-secretion, and both comb and space favor that content which tends to prevent swarming out and drifting to neighboring hives. (At the recent convention of the Southern Idaho and Eastern Oregon Beekeepers' Association, Mr. G. J. Yoder strongly advocated quickly *driving* the bees from a foul hive into the new hive, doing the work when the bees are gathering heavily, say between 11 A. M. and 4 P. M., as the driven swarm is far less likely to "drift" or to swarm out than if *shaken*, with the added advantage that night work is avoided.) Whatever the actual method of removing the diseased combs, all such combs, together with all combs used for three to five days on the Chantry plan, are now stored where no bees can reach them. The apiary may now be supered, after putting an excluder on each colony. When it is time to extract, if at all fearful of reinfection from yards near by, we remove the supers and the excluder, lift a comb or two, when, if no disease is apparent, we remove the supers to the shop for extracting. If a few colonies are found with a little disease, and the season is too far advanced to be worth the trouble of curing such colonies, we see that the bees have as much room as they can fill, above the excluder. Then as the flow wanes, they should be sulphured, and all the combs stored where they will be secure from robbers.

If it is possible to spare the time, when the last flow is waning every colony should be inspected. If one waits until the flow is over, robbers may be so bad that inspection of a large yard will be impossible unless, perhaps, the feeding of a large amount of very thin syrup might keep the bees so busy as to allow them to be handled the same as during a flow.

One of the greatest aids is to get out and clean up neighboring colonies, or to get the inspector to do so. If one has the time, and cares to risk the mere presence of the disease in the yard, he can save every diseased colony that has enough bees to winter. The plan consists in simply contracting the entrance and fitting an Alexander feeder under the hive, with extra care to have every thing tight. When all brood has hatched,

some time late in the fall give the bees a feeder full of warm syrup at 4 or 5 P. M., and in an hour give them another. Then when they have stopped flying, brush them into a new hive with as many solid combs of sealed honey as they can cover. By filling with warm syrup the bees to be cured, we effectually prevent any chance of failing to cure the disease by the above method, though we seldom bother to cure any cases found late in the season, as bees are easy to raise here, and we prefer to remove all chances of infection earlier in the season.

When the season is over, one should be ready to melt the combs taken from diseased colonies. Have your steam-boiler standing outside the shop; run steam inside through a half-inch pipe, into both wax-presses, and into several barrels or tanks. Melt the combs either by direct steam or by boiling, as preferred; then when there is a lot of hot melted comb, fill a press, put on the pressure, begin to melt more combs, occasionally turning down the jack-screw of the first press, then fill the second press and repeat. About the only limit to the amount that one can render is the limit of the steam supply. It is not wise to get too small a boiler. With our powerful presses we get the best results by pressing the first time, just as the melted comb comes from the boilers, taking care to dip up plenty of water with the comb, but having a little steam constantly running into the press. After the wax ceases to run in a decided stream, we loosen up the screw, fill the press with boiling water, turn on more steam, which shakes up the slumgum, causing it to take up more water; again apply the pressure, finally drawing off all the wax and water into a deep Aikin wax-separator, which runs the wax into one can and the water into another, where it may be used again.

Any combs, either from the brood-nest or super, that show no disease may be extracted if the honey is not candied. The extractor should be a small one, used for no other purpose. Combs of candied honey (provided the old brood-combs are not full of cocoons) may be run through the Powers capping-melter. Such honey may be shipped in winter, to be used for manufacturing purposes if one has a market for such goods.

If diseased honey is to be saved for feed (and the bee business is not such a bonanza that it is not necessary to save every such by-product), we now have a new method of saving all of it. When rendering, we cut out any diseased parts of combs containing some honey; pile these frames and combs of

honey in the capping-melter; cover with doubled canvas, and steam. The honey, somewhat thinned by the steam, runs out at a great rate, is separated from the wax, and then canned. This is somewhat similar to the method recently described by Mr. Wesley Foster, p. 473, Aug. 1, 1912, but by using a big steam supply from a regular boiler the work is more rapid. If we have much honey to save from diseased combs another year, we expect to build a large cupboard of galvanized iron in which shelves of combs, standing, may be shoved, so as to melt a large quantity at once.

In the footnote to Mr. Foster's article mentioned above, the editor intimated that such a process sterilizes the honey; but our tests compel us to sound a warning, as we find that a temperature of only 180 degrees Fahr. is reached by the honey so steam-melted. Of course, a saving of fuel would result if the honey so melted were at once boiled over a fire. Before feeding such honey we dilute it until it is about one-fourth water, then boil it over gasoline-stoves (so as to control the temperature, thus avoiding boiling over and the danger of fire). For this purpose we use wash-boilers with a cover on each. We do not put on the cover at once, as honey which is being heated has some queer notions. When it first begins to boil, one must watch closely, turning down the blaze as necessary, and stirring. Then, as a rule, after it has boiled for perhaps five minutes, the tendency to boil over is past, and the cover may be put on the boiler. The cover should have a one-fourth-inch hole in it, at the top, where the steam may escape. Do not go away and leave the boiling honey, as some lots will again boil over unless watched and stirred, while other lots will boil furiously without danger. We boil the honey for fifteen minutes at least; then a few days later, usually when the honey is needed for feed, we again boil it for about five minutes.

If the directions which have been given are followed, using a cover on each boiler (an idea that we obtained from Mr. R. D. Bradshaw, of Payette, Ida.), the feed is so safe that I have felt no anxiety in using it freely, in outside feeders, in yards of as many as 275 colonies.

When through rendering, the floor and walls, as well as the tools and clothes, should be freely sprayed with a very strong carbolic solution, so as to avoid any chance of the bees picking up any thing that might lead to the disease; for, even if the carbolic solution should fail to kill all germs and spores, the strong odor is so objectionable as to prevent bees from working on any

thing sprayed with it. The disease of which I have written is the real so-called American foul brood, with which I have had to contend most of the time, in one or more yards, for more than a dozen years, twice having to melt the combs from an entire yard.

Meridian, Idaho.

BEEKEEPING IN THE ISLAND OF CYPRUS

The Progress in Apiculture as Seen by a Veteran Beekeeper

BY M. G. DERVISHIAN

I am glad to say that, about twenty-nine year ago, when I started beekeeping at the town of Larnaca, on the island of Cyprus, I was a reader of *GLEANINGS* for a few years. Then I received a copy of the *A B C of Bee Culture*. I sincerely confess that, during the period of twenty-three years, when I was without *GLEANINGS*, I was a loser. Two years ago I subscribed again for *GLEANINGS*. I take great pleasure in mentioning that the improvements in bee culture during the last twenty years appear to me to be wonderfully great. These improvements are, no doubt, attained to a great extent through the instrumentality of the beekeeping journals in which the experiences of many prominent beekeepers are concentrated and discussed for the benefit of all the readers.

Naturally, in the past twenty-three years necessity and close observation have taught me a few things which I now have the pleasure to put before my fellow beekeepers.

COVERING THE TOPS OF FRAMES.

Many years ago I used to cover the tops of the frames with oilcloth or with a thick cotton cloth. I discarded the oilcloth because it kept the inside of the hive damp. The use of the cotton cloth was becoming very expensive because the bees were always gnawing and piercing the cloth; and besides this they wasted a great deal of their energy in propolizing it. Each time, when the cloth became worthless on account of many holes in it, it was thrown away, together with the propolis, as this could not be scraped off and returned to the bees. I therefore discarded the use of the cotton cloth also, and commenced covering the top of the frames with a thin wooden lid in three pieces. At first I used to nail wooden bars half an inch wide by one-fourth inch thick around this lid in such a way as to provide a bee-space between the tops of the frames and the inner surface of the lid. Seeing that, in so doing, the bees were building bridges and wasting wax and pro-

polis I discarded this kind of lid and replaced it with wooden bars about three-eighths inch thick and two and three-quarters inch wide, each bar to cover exactly the tops of two frames from end to end. These bars are put flat on the tops of the frames without leaving any bee-space. I have twelve frames in each hive, and I use six such wooden covers for every hive. This arrangement gives me great facility of movement, as I can remove as many as I like of these six covers; and I scrape off the small amount of propolis, which I return to the bees. For re-covering the tops of the frames I slide the scraped faces of these bars (covers) on the frames longitudinally, commencing from the ends of the frames. In this way not a bee remains between the tops of the frames and the cover; for when sliding the bees (if any) are pushed away. I found this last method of covering bees to be the most economical and the safest. The use of smoke for driving bees down from the tops of the frames is obviated. I find that it is desirable to make use of smoke as seldom as possible.

MY WAY OF MANUFACTURING COMB FOUNDATION.

Within twenty-nine years I have received three comb-foundation machines. According to my idea I have made a step forward in the manufacture of foundation. I make use of sheet glass (strips of ordinary window pane) dippers instead of sandpapered wooden dippers. So I save the trouble of sandpapering the wood, and I get better and more even sheets. Another advantage of the glass dippers is that glass cools quickly. In case, through a mistake, the wax sticks to the glass, I immediately clean it with a very small piece of linen soaked in a solution of carbonate of soda. For melting the wax I make use of a tall enameled vessel. I put into this vessel about three inches of water, and over this water I put the wax and set it on a petroleum-stove. When the wax has melted I reduce the flame of the stove to such an extent as to keep the wax in liquid state, but below the boiling-point. All the impurities, if any, settle down into the water. Then I wet the glasses and dip them one by one into the liquid wax. I repeat this dipping three or four times just to get the sheets of wax sufficiently thick for passing them through the rollers of the machine. Before putting the wax sheets through the rollers I dip them in water, warmed to about 90 F., until the sheets become sufficiently soft. I find it is essential that the rollers should be cool and the wax just warm—i. e., soft enough to get the desired even and thin comb foundation.

Of course I starch the rollers before using. By using these glass dippers, and following the printed instructions sent to me with my comb-foundation machines, I have been successful in manufacturing the thinnest possible and finest comb foundation.

Nicosia, Island of Cyprus, Dec. 19.

To be continued.

[We are glad that our correspondent, after having served for many years as a government official, has now the leisure to return to bees and beekeeping. He is now training his six sons in apiculture, and also in sericulture (the growing of silkworms). The young men are now contemplating starting a series of out-apiaries, and they are expecting to equip them with American hives and fixtures. They already occupy an important position in the beekeeping interests of the island of Cyprus, and are the only rearers and exporters of Cyprian queens there.—Ed.]

THE QUESTION OF ALFALFA HONEY IN THE EAST

BY WESLEY FOSTER

Mr. Crane has drawn the inference that it would be better if all Western honey were marketed in the extracted form, and that alfalfa honey granulates more quickly than Eastern honey—April 15, p. 224. As to the first proposition, I will say that the time is a long way off when all Western honey will be extracted. The past season, extracted-honey production was overdone in the West, and comb-honey production fell short of the demand. There is one fact regarding Western honey that all readers should thoroughly understand. Pure alfalfa comb honey will scarcely granulate at all. The case of comb honey that was awarded first place at the exhibit of the National convention in Denver a few years ago was two years old, and showed no signs of granulation. I think that Dr. Miller was one of the judges. There are many carloads of pure alfalfa honey produced in Idaho, Montana, Wyoming, Utah, Colorado, Nevada, Arizona, and New Mexico; and if in the comb this honey will show hardly any signs of granulation within a year. But we also produce a large amount of honey from sweet clover, alfalfa, clover, and wild flowers mixed. This honey will granulate sooner, so should be on the market early, and should be consumed before the holidays. I will make this point of early marketing of this comb honey as strong as possible.

Alfalfa extracted honey will granulate readily into a hard white "cheese," and it would doubtless pay to develop a market for this article; but the educational campaign necessary will cost money.

Western honey has developed a market for itself. I should like to have the opinion of the largest buyers of Western honey as to why it has stolen a place in Eastern markets, commanding 25 cents a pound. If Western honey can capture such a market it must have pretty good quality back of it. Perhaps the fact that Western honey can be secured by the carload, and the dealer is able to supply a more uniform grade and style of package throughout the year may have some effect in giving it the preference.

There is one thing that I noticed in the Chicago market, and that is that Western honey is produced in the standard section almost altogether, and marketed in single and double tier cases, while I saw Eastern and Middle Western honey in four or five different sizes of sections, and as many different kinds of shipping-cases, with no standard grading rules. I do not think that the markets can be injured by having honey supplied at all times of the year, and that is what the West has partly helped to do. We are not perfect here in the West. We have the problem of poor grading, and some of it dishonest in its methods, but the West is not alone in this latter particular.

As long as we are selling our honey under the competitive system there will be more or less clashing; but there is room for all who can produce the article that the market demands. And I do not believe that it will be so difficult to secure national grading rules. We shall then have honey-grading schools conducted at all of the conventions and bee meetings, and the unity of the methods and interpretation of the rules will correspond all over the country.

Boulder, Colo.

Oregon Fruit-men Planning to Keep Bees for Pollenation of Fruit-trees

There is a good prospect for a good crop of fruit here. If favorable weather conditions continue the colonies will be strong for next spring.

Most of our orchard men are going to install a few colonies of bees in their orchards in order to pollenize the fruit. They are just beginning to find out that they can not raise fruit without the honeybee. I wish all the rest of the farmers would do the same throughout the whole country. Then we could call this the land of honey and plenty of money.

The Dalles, Oregon.

JOHN PASHEK.

Heads of Grain from Different Fields

Tendency to Revert Back to Black in Color; the Origin of Foul Brood

1. Is not the honeybee of America a dark bee? and have not all other yellow imported queens a tendency to produce bees that become dark after several generations, irrespective of meeting with dark drones? I mean, is it not a continental tendency, as the black man is to Africa and the yellow to Asia?

2. Is not foul brood caused by *condition* as well as by *contagion*, the same as diphtheria in the human? A queen run to her utmost limit in egg-laying naturally becomes low in vitality. Her brood fails to develop—dies, and becomes foul. The same holds good in poultry run at high pressure, and handled under artificial conditions.

Slate River, Ont., Can., Jan. 8. J. M. MUNRO.

[1. The native bees found in this country in the early days were black—very similar to and perhaps identical with the German black bees, but probably somewhat different from the black bees of Great Britain. At the present time Italians predominate largely in many localities, especially where bees are kept in modern hives. But there are certain localities where black bees are the only race to be found.

The extra-yellow Italians that have been bred for color have a tendency to revert back to the original type. In southern Italy the bees are yellower than those in the northern part of that country. If the original type was leather-colored, then the yellow strain will show a tendency to revert to the leather color—that is, of course, supposing no effort is made to breed from yellow drones and light-colored queens. But in many localities Italians will cross with the native black bees. In such cases we have a hybrid of two races. If the predominant bee in any locality is a native black bee, then any other race on the yellow order introduced would, in a short time, become so much crossed with the black strain that we would have nothing but black bees. We do not believe that the habitat has any thing to do with the color of bees; but the blacks are more persistent—that is to say, they have greater power to force their way into new territory than the Italians have.

2. Strictly speaking, foul brood or any germinal disease is not caused by condition; but a condition may be such that a disease finds a more ready lodgment if the germs of the disease are *already present*. Speaking more specifically, no amount of rotten brood caused by chilling or overheating will develop into foul brood. But rotten matter, or bees in a weakened condition, if they do not properly take care of the brood, might help the propagation of disease already present in the form of spores when a healthy colony or well-fed brood would throw it off. In the human family a healthy individual will resist disease much better than one who is all "run down," and the same general rule applies to bees. Let it be clearly understood that corn will not grow where no corn has been planted; neither can disease develop, no matter how favorable the surrounding conditions, when no disease germs are present. This fact has been conclusively proven.—Ed.]

Can Increase and a Honey Crop Both be Secured at the Same Time?

I have been a subscriber to GLEANINGS for a number of years, and have learned many things from it that have been of value to me in beekeeping. I have nearly all of the books you publish on beekeeping, but can not find exactly what I want on increase. My conditions are as follows: I have one hundred colonies in two yards. Practically my whole surplus honey is from clover and basswood. I run my bees on the Alexander plan for honey, and have no swarming to speak of. Our honey, coming as early

as it does, I do not care to increase by the Alexander plan. I wish to double my number without decreasing my honey crop. I have plenty of hives and foundation. Would I succeed if, instead of placing the brood above the excluder, I would take one frame of brood with the queen, one frame of honey, and one empty comb, and start a nucleus from each strong colony, giving each old stand a young queen in two or three days?

Spring Green, Wis., Jan. 7. G. H. PECK.

[It is practically impossible to double your number of colonies without decreasing your honey crop; that is to say, you can not double the colonies and produce a honey crop both at the same time. You can make increase, but at the expense of your crop. You can, however, do this: Run your colonies in the regular way; get them as strong as possible, produce the crop, and then, after the crop has been secured, divide and build up the nuclei by feeding. The plan you propose would be perfectly feasible. Of course, you need to bear in mind that, after the honey-flow, and the crop has been secured, the robbers are inclined to cause more or less trouble; and in the feeding you will need to exercise more than ordinary precaution to prevent robbing.—Ed.]

Warm Weather Causing Much Brood-rearing in the South

In the fall I fed my bees about 15 pounds of sugar syrup, made a little less than three parts of sugar and one of water. They had the hives practically full of good sealed stores the last of November; but every warm spell I could notice that they were raising young bees, from the fact that they would bring out some dead ones after we had had a cold snap, and this I suppose to be chilled brood.

I wrapped my hives well with old newspapers, and then covered them on the outside with three-ply roofing paper. On the 6th of January I noticed the bees bringing in some pollen; and every warm day that we have I notice that this pollen increases considerably—that is, the bees seem to bring it in more freely. On Sunday, Jan. 19, I noticed that they were coming in with quantities of pollen, and working as in summer time. I could not imagine where this came from, so I hitched up my horse and drove to the country, and found that it was coming from the alder, of which we have an abundance.

Now, what I want to know is, will not this pollen coming in start them to raising brood very freely during this warm weather? and when they consume what stores they have in rearing the brood, if we have cold weather in February (which we generally do) are they not liable to starve? I can feed the bees during warm days; but I do not know whether to feed them with thin or thick syrup at this time of the year. Our weather here is very warm. Some days the thermometer stands at 75, and we have had but very little freezing weather. Our hives are running over with bees, and we do not want to lose them.

Kinston, N. C., Jan. 21.

J. W. BLACK.

[During a warm open winter such as we have been having, bees in the South will rear a considerable amount of brood provided they can secure natural pollen, and they will do a good deal of brood-rearing, oftentimes, without natural pollen coming in, if there is pollen in the hives, which is generally the case. As you surmise, there is danger in such cases that the bees will use up their stores to such a point that starvation will follow. If you fed your bees 15 pounds of thick sugar syrup, as explained, so that the hives were practically full the last of November, we feel quite certain that there will be enough to carry them through until spring.

We advise the examination of a few colonies; then, after making the examination, "heft" the hives so as to make a note of its weight. By thus "hefting" the other colonies of the yard you will be able to form an idea of their relative amount of stores. If there is danger of your having cold weather in February we would advise, in case it is necessary to feed, a thick syrup about the same as you fed them last fall. If it should be too cold to feed, give them candy, made as directed in the A B C and X Y Z of Bee Culture; but in the kind of weather you have been having, there will be no trouble about feeding a sugar syrup.—Ed.]

The Warm Winter Weather Causing Bees to Fly and Rear Brood

Is it dangerous to permit the bees to fly at this time of the year? I presume not, from what I have gathered by reading; and, in fact, it is practically impossible to keep them in the hive, inasmuch as we have had spring weather since Christmas. The three first weeks of January have been like April here in Washington. Yesterday, the 19th, I noticed a number of my bees having pollen on their legs. Where they secured it is a mystery to me; but yet it is a fact that they were gathering, to a small degree. I believe this is a remarkable record for January. Last year we had "bitter" weather at this time of the year; in fact, all of January and part of February was such weather as to cause the thermometer to register around zero, or from 10 to 15 degrees above, for nearly two weeks or more.

Is there any thing you can suggest as to ascertaining whether the stores are sufficient to carry the bees through to spring? The hives are all closed up, packed, and the packing covered with oilcloth, and hence I can not open them; but I thought you might have a suggestion to make as to how to ascertain whether the stores are sufficient, or how to save any weak colonies should their stores be low. Perhaps you can advise as to whether there is a method of feeding bees at this time of the year; but inasmuch as the bees are coming in and going out as if they were in a healthy condition, I presume there is nothing to do but let matters rest as they are with my colonies until spring.

Washington, D. C., Jan. 20. E. E. VROOMAN.

[You can not prevent bees from flying when the weather is suitable; in fact, it is better that they should. We refer you to the reply to J. W. Black, above, for Mr. Black is located in about the same kind of climate.—Ed.]

Unlawful to Ship Diseased Bees from One Locality to Another

Please inform me regarding the necessity of having bees inspected prior to moving them from one State to another. I wish to move mine next spring before the honey-flow will warrant inspection without robbing. Do you mean to say in the A B C and X Y Z of Bee Culture that no bees can be shipped with safety while there is the least bit of foul brood present? It seems to me that, if the few colonies were cleaned up, they would be permitted.

Idaho.

SUBSCRIBER.

[Under your foul-brood law you would not be permitted to ship bees from one locality to another in your State until they had been inspected by the State foul-brood inspector or his duly authorized agent. They could easily be inspected before the honey-flow; but perhaps you mean you desire to have them moved before warm weather sets in, so that the brood of the colonies could be examined to see whether it contained any diseased matter. There probably would be no brood at that time.

It is not safe nor wise to try to ship colonies of bees that contain infection, be it ever so small an

amount. If a single cell shows diseased matter we would not ship the colony, because a single cell may develop into a rotten condition throughout the entire colony.—Ed.]

A Good Record in Favor of the Danzenbaker Section as a Globe Trotter

Early in September I was commissioned by the Provincial Department of Agriculture to prepare an exhibit of honey, etc., for the agricultural fairs of Victoria, Vancouver Island, and New Westminster on the mainland of British Columbia and for the dry-farming congress, Lethbridge, Alberta.

The comb honey was in 4 x 5 x 1½ Danzenbaker sections; and I think, taking into consideration the miles traveled (about 1800), and that the combs were handled from wharf to railroad depots, from depots to wagons something like thirty times, and yet arrived back to Victoria without a section, comb, or single cell being damaged, is a wonderful record.

The sections were packed 1½ in a glass-fronted crate, 3½ inches wide, about ¼ inch play at sides and ends, one layer of sheet cotton batting on bottom and top of sections, and lid nailed on. The crates were packed four in a used candy-box, two deep and two wide, glass fronts toward each other, with sheet of corrugated paper between. On the bottom of the box were two inches of excelsior. Between the two tiers of crates was one inch of excelsior, and two inches of the same packing on top of all. Between the sides and ends of the crates and the sides of the box were three inches of excelsior, all packed as solid as hands could pack it. There was much doubt as to results when the final trip home of 800 miles by freight, which took 21 days on account of an accident on rail, was started; but every thing arrived in good condition—no shake in the big box, not a glass or comb broken, nor a cell of honey leaking. The sections were all selected for exhibition purposes. The combs were well filled, and attached right to the edge of the sections. These were displayed in glass-covered trays holding 24 sections, presenting one solid slab of snow-white honey 24 x 30 inches, and were the admiration of all who saw them.

Now for the secret of success. The combs were one solid mass, with no empty spaces as with beey sections, no shake in crate, excelsior packed firm; just sufficient spring to receive concussion of rough handling, but resiliency to resume its former position before the shock.

TABLE OF DISTANCES COVERED.

Total1794 miles

About 30 handlings took place.

About 100 jars of extracted honey were packed in excelsior; not one broke.

It is very different with straw, so frequently used in comb-honey packing. Straw, when once flattened, remains so to a certain extent, and leaves too much

space for the comb honey to shake about. In moving bees from place to place in wagons, I always use hay, as it is much more resilient than straw.

Victoria, British Columbia, Canada, Nov. 27.

Would Albuminized Sugar as Feed and Substitute for Pollen be Practical?

In reading the article, "The Physiological Effect of Feeding Sugar," p. 817, Dec. 15, the thought came to me, "Why not feed albumen?" If pollen, which is so rich in albumen, is so essential to brood-rearing, why not feed albumen in a concentrated form? A substitute for pollen would be hard to find; but the white of an egg is rich in albumen. To the beaten whites of eggs add pulverized sugar until it forms a soft mass about the consistency of dough, and feed as you would hard candy or fondant, or add the beaten egg to sugar syrup previously cooled so as not to cook the egg, and feed in any of the various feeders. Feed this albuminized sugar or syrup in early spring to prevent spring dwindling, and to encourage brood-rearing.

Now I am only a novice at beekeeping, chickens being my hobby. The laying hen must be supplied with an abundance of protein and other foods essential to egg production. According to Dr. U. Kramer, pollen (albumen) is essential to brood-rearing, and the bees' welfare in general.

I have never tried this albuminized sugar or syrup feed. It is only a thought which came to me while reading Dr. Kramer's article. Do you know of its being tried? Do you think it practical?

Kansas City, Mo.

MRS. H. MILLARD.

[Bees can usually obtain natural pollen as soon as the weather is safe for extensive brood-rearing; but under conditions where the natural pollen is too scarce we think the feeding of some such substitute as rye meal out of doors would be much cheaper and more satisfactory than the expensive white of eggs, even if the latter would supply all the elements needed—a supposition which we doubt.—ED.]

How Much has Location to do with Success in Working Bees for Honey?

Two years ago I sold some of my land in South Carolina, and in casting about for an investment I decided to move to Georgia, within eight miles of Augusta, where I could engage in the trucking business and also work my bees for honey. I practically had to give up queen-breeding on account of not having help at that time. I found the best roads around and near Augusta that I had ever seen. The land for six miles out is a black loam; but after passing these six miles we come to high dry sandy soil, with a scrawny growth of oak and long-leaf pine, identical with many lands in Florida. We finally decided to locate on a hill about a mile long, where the atmosphere is dry and pure.

When I moved I brought 20 or 25 colonies of my best strain of Italian bees, and some of these were taken off the wagon and placed directly on the ground without even a bottom-board. The bees have not been harmed by ants or other insects. I have never seen ants disturb a colony, notwithstanding many are in this soil. I thought from all appearances the territory around would be good for bees; but I have been here now two seasons—one a very dry year, and the other wet and seasonable throughout the year, and a large portion of the time too wet. Although there were many ideal days, both in spring and summer, I have secured but little honey, even extracted, for I do not work for comb honey. The cotton failed to produce honey here this season, and also the asters and goldenrod; and yet there were times when I thought conditions were ideal.

I can not account for this, except by climatic influences. There are swamps and the Savannah River within five or six miles. I write to give my fellow readers this experience, and to show that there must be about as much in location as any thing else; and it may be that some can account for the conditions here by some other theory.

I note that the shipping of bees by the pound from the South is recommended in order to build up weak colonies north. This is practical and profitable. Several years ago, when I commenced shipping bees and mailing queens, we shipped a good many bees by the pound; but for some reason it was discontinued, and the nucleus system took its place. Last year I shipped a few cages of bees to Canada with perfect success, and would have shipped a good many to the party; but in the mean time they sold out their bees and ordered shipments discontinued. The cages manufactured are well adapted to this purpose. While I did not get much honey this year, my bees are in fine condition for the coming spring.

Augusta, Ga., Dec. 31.

J. D. FOOSHE.

[Mr. J. D. Fooshe is one of the most experienced queen-breeders in the country. Our older readers will recognize him as the man who was able to raise such fine stock in the days gone by. In the last few years he has somewhat dropped out of sight, and the letter above explains why. If there is any man who can make a success of shipping bees in pound lots, Mr. Fooshe would be the man to do it.—ED.]

"Bulk Comb Honey" or "Chunk Honey"? which is the More Distinctive Expression?

I note that your Texas correspondent is very anxious that the term "chunk honey" be dropped, and "bulk comb honey" be substituted. "Bulk comb honey" is descriptive, but not more so than the less cumbersome term "chunk honey," and is misleading when applied to a mass of chunk honey with a quantity of extracted honey to fill up the spaces. His plea that the product originated in Texas would indicate a greater antiquity for the honey industry in that State than most of us were aware of.

Before we heard much about Texas as bee territory I produced and sold considerable quantities of chunk honey in Iowa; and about 1856, when I was not more than four years of age, I ate chunk honey in Illinois, and I distinctly remember the flavor of sulphur, which proclaimed the process by which it was commonly obtained in those days, viz., by smoking the bees to death, "taking up a hive" and cutting out the chunks.

But the product is evidently older yet, for it must have been chunk honey which Samson took from the carcass of the lion, and that, if I remember correctly, was several years before Texas was annexed to the United States.

BURDETT HASSETT.

Alamogordo, New Mexico, Nov. 21.

[There is considerable truth in what our correspondent says, and ordinarily we prefer the shorter term; yet, on the other hand, it is true, we think, that there should be a distinction made between the modern "comb honey in bulk" and the old-fashioned "chunk honey" obtained by sulphuring the bees. We ourselves are inclined to agree with Mr. Scholl, therefore, as we feel that bulk comb honey is really the more distinctive and dignified term.—ED.]

Why Not Send Pound Packages of Bees by Parcel Post?

Referring to the editorial, Dec. 15, p. 787, regarding pound packages of bees from the South to the North, I wish to say that it is the greatest plan ever promulgated. One of the best things about this business is that the packages of bees are young ones, and, consequently, will live longer than the wintered bees,

and they will be worth as much to the northern man as twice the number of wintered bees. Yes, it is a success. I have sent hundreds. I am able to guarantee safe arrival and satisfaction on packages when a queen is with them. They do not always go through as safely when they have no queen. I have 550 queen-mating boxes, and 500 full colonies to produce bees and honey, and an excellent southern location. I can send out 500 or more packages of bees a month after April 15. Why can't they be sent by parcel post?

Fitzpatrick, Ala., Jan. 3. W. D. ACHORD.

[We have looked up the parcel-post ruling, and it seems to us very clear that bees can not be sent in regular pound and half-pound packages. A modification of the ruling may be made for us later. However, ruling or no ruling, we believe it would be unwise for the average beekeeper to undertake to ship bees by parcel post. This new old method needs to be tested a little more before it can be considered safe to undertake it. About thirty-five years ago an ignoramus undertook to send about $\frac{1}{2}$ lb. of bees in a paper box by mail. They got loose, of course, in the mail-car, and stung the employees. The result was a ruling that tarred even queen-bees with their attendants from the mails. It was a matter of a year or two, coupled with a good deal of hard work on the part of Prof. A. J. Cook, now of California, and others before the ruling was rescinded. See GLEANINGS, page 106, for March, 1880. It would be folly to repeat this experience, and for that reason we urge the importance of waiting until we have a combless cage perfected. Then we can go to the Postoffice Department and show what we can do, and probably secure a ruling in our favor.—ED.]

Double Wire Cloth for Better Ventilation in Combless Bee-package

I have made only one trial shipment of a package of bees without comb, sending a pound of bees confined to the package 46 hours with only three dead bees at the end of that time. I made the package $4 \times 6 \times 8$, of $\frac{3}{8}$ -inch square stuff with one fence-like piece through the center for the bees to cluster on. After making the frames of the $\frac{3}{8}$ stuff, 4×8 , I covered both sides with wire cloth. This gives a space between the wire cloth of $\frac{3}{8}$ inch for air, if there should be other packages piled on or over the bees. I then nailed on the bottom and two strips $\frac{3}{4} \times \frac{1}{2}$ to form the ends, which I also covered on both sides with wire cloth. The candy cage is fastened on the floor. Then I cut a piece of heavy felt about 6×6 inches. I waxed the floor well where I placed the felt. This felt I soaked in water, then tacked it to the waxed part of the floor.

For the cover I bored four two-inch holes, and covered them with wire cloth except one through which I shook the bees. I covered this with wire cloth. On this cover I fastened a convenient handle for the railroad men to use in lifting the package. I also put a strip of paper on the cover, with the following directions: "Live bees. Do not cover tightly. No handling if handled reasonably."

Hartville, O., Nov. 5. J. A. KREIGHBAUM.

[Double wire cloth, the same as is used in ordinary queen-cages, is hardly sufficient protection. Single wire cloth, with a wooden grating, is better, in our judgment. Packages that go by express or parcel post should be so protected that the sharp corners of the box or other articles will not punch through and ruin the contents. In the case of a package containing bees, even a small hole would cause no end of trouble, to say nothing of the loss of bees. The wooden gratings that we recommend are narrow slats about $\frac{3}{4} \times \frac{1}{4}$ inch thick. In the case of larger packages, the strips should be $\frac{1}{2}$ or even heavier.—ED.]

How Does the Queen Face when Laying?

I have been waiting patiently to see whether some one of the lynx-eyed American bee-students would not point out a peculiarity in the piece of comb illustrated on page 657, Oct. 15. The cells are built with two sides horizontal. Very unorthodox of the bees! You are scientifically cautious, Mr. Editor, when you remark on page 647 that "it is safe to say that a queen while she is laying an egg *usually* has her head toward the upper part of the comb;" but I can not agree with you, after all. I have had two or more observatories in constant use for the last three or four summers, and we have often watched the laying of the queens. Whatever attitude she may be in when she inserts her abdomen into the cell, she almost invariably twists round before the actual process of laying is performed, in such a way that her head is toward the *lower* part of the comb. As a rule, too, she is not looking right downward, but has her head turned slightly toward the end of the frame to her right.

Perhaps you will allow me to express my keen appreciation of GLEANINGS, and the way it is conducted. I begin almost to be personally acquainted with the editors and some of the contributors, and I just love the kindly way in which they sit upon each other when one has been caught napping. I am glad to see that you have a due appreciation of Mr. Sladen. So far as I can see, he should never have been allowed to go to America. There, now!

JOHN ANDERSON, M. A., B. Sc.

Stornoway, Scotland.

[We have examined many pieces of naturally built comb, and have found that, while the two parallel sides are usually vertical, still there are a number of exceptions. We may say, then, that naturally built comb of both types is found, but that the predominating type is that in which the two parallel sides are vertical.

Concerning the position of the queen when she is laying, there are so many exceptions to any one rule that perhaps we put the matter a little too strong, even in our general statement to which you refer. Two of our queen-breeders agreed that the queen usually has her head toward the top. However, if we are not correct in this we shall be glad to know it.—ED.]

Exhibits at the Oklahoma State Fair

We noticed your error in the display picture on p. 811, Dec. 15; also your correction on editorial page, Jan. 1, with Mr. Van De Mark's letter quoted therein. The only part of Mr. V.'s letter to which we could possibly take exception is his statement that "there were four others nearly as good," and presumes he means to include our own exhibit in the four.

The records of the State Fair Association will show that of the nineteen classes offered for bees, honey, wax, and allied products, we entered seventeen, winning a ribbon in every class we entered, getting nine firsts. The other firsts were awarded, five to Mr. Bartholomew, four to Mr. Crouch, and one to Mr. Burrage. After winning as many firsts as any other two exhibitors in as big a honey show as this, we dislike very much to be placed in the "also ran" class.

Noble, Okla., Jan. 10.

GAREE & GAREE.

Danger of a Lack of Stores Toward Spring

Bees are wintering finely. Some beekeepers will be troubled toward spring by a shortage of winter supply of honey in colonies. Clover is very promising up to date. A good stand of white clover is to be seen in every pasture and field in which it is allowed to grow. The season of 1913 promises to be a good one in my locality.

Unionville, Mo., Jan. 24.

FRED H. DRURY.

Our Homes

A. I. ROOT

To him that overcometh will I give to eat of the tree of life, which is in the midst of the paradise of God.—REV. 2:7.

Do ye not yet understand, neither remember the five loaves of the five thousand, and how many baskets ye took up? neither the seven loaves of the four thousand, and how many baskets ye took up?—MATT. 16:9, 10.

(A sequel to the *Home Papers* in the Jan. 15th issue.)

In the second and third chapter of Revelation there are some glorious and wonderful promises to those who "overcome." I wish the readers of GLEANINGS would look them up. I have chosen one of them for my text for this Home paper; and as I dictate here the first page of that Home paper (that was lost) I do it to illustrate how many times in this busy life it is necessary to exercise great patience and perseverance, and holding on. Huber has explained that it was the intention of the Root Company to send me a dictaphone in order to help me to keep up my Home Papers while I was in Florida during the winter. I was told arrangements were made so the dictaphone would probably be here early in November about as soon as we arrived; but after going to the express office again and again, and not finding any thing of the dictaphone, I wrote to Huber. He replied, and said he supposed it had been sent promptly long ago. This was somewhere about the first of December. The company, however, without giving any explanation of their remissness, finally wrote that they had finally forwarded the dictaphone to my address. Then I commenced going to the express office again and again, inquiring for something for A. I. Root. Being told continually that there was nothing, I finally, one day, remonstrated. I said, "Look here, friends, a dictaphone has been shipped to me from Cleveland. It is an instrument worth something like \$100 or more, and it is in a large box, and it seems to me it *must* be here somewhere."

At this the agent replied, "Oh! it's a big box that you wanted, is it? Well, I remember there is something of this sort here, after all, and it has been here some time."

When he hunted it up he found it was directed to The A. I. Root Co. instead of to A. I. Root, and this gave him an excuse for saying, over and over again, there was nothing for me. I got the box home as soon as possible; and then, in order to be sure that the instrument was not injured in any way, I unpacked it very carefully myself, looking all the while for some directions for setting it up and handling it. Not a scrap of any thing could be found; neither was there a

mouthpiece anywhere in the package to use for dictation. I wrote a remonstrance to Huber, and he said something like this: "As the machine was expensive and complicated, the manufacturers never had furnished printed directions for use, but they always sent a man along to instruct the purchaser how to operate and see that he got along all right." As they had already sold the A. I. Root Company several machines, they probably supposed that every member of the firm ought to know how to use them. And this, in fact, is true. Several times last summer Huber did remind me that if I was going to use a dictaphone down in Florida I had better come into the office and practice on it awhile; but I was so busy in building that bungalow that it was put off and neglected. It is true, however, that I did have one down here a year ago, and under Ernest's tuition I dictated a little matter on it. The fact is, I somehow dreaded using the machine, feeling a sort of embarrassment talking to a piece of "machinery" instead of talking to my long-time friend and standby, W. P. Root, who has for so many years taken down all of my dictation. My correspondence was already far behind. I had a lot of things that I wanted to say to my readers since coming here to Florida, and it was of the greatest importance that the dictaphone be got in trim. Perhaps I might explain right here that for many years past it has been a very hard matter for me to use my right arm and do much writing. I can drive nails and hoe corn and "fuss with chickens" all right; but when I come to get a pen or pencil in my right hand and sit down to the desk, there is a sort of writer's paralysis that has troubled me more or less for forty years. There was no way but to "cipher out" how to use the complicated instrument, even if I did feel much hesitation in undertaking to pull to pieces any thing so complicated and difficult. I was tempted many times to give it up; but then I recalled how it spoiled my enthusiasm and energy to acknowledge myself defeated in any praiseworthy undertaking. It really *hurts* me, and for that matter it hurts *anybody*, to acknowledge himself defeated, and give up in something that really *ought* to be done. Under the circumstances the dictaphone seemed to be almost the only outlet that would permit me to keep up my department of the journal, and was almost the only way to continue to lend a helping hand to those who love poultry, high-pressure gardening, and

the different branches that I have been so long writing. Perhaps I may confess to you that I prayed over the matter again and again, asking the dear Lord to give me back the skilled and expert use of that right hand for just a little while. I thought of the little couplet:

Backward, turn backward,
O time, in thy flight;
Make me a child again
Just for to-night.

Will our readers now turn to page 68, GLEANINGS for Jan. 15? * The broken cylinder must evidently have cut short a part of that concluding sentence, and Huber ended it for me, for I had the speaking-tube already in my hand but could get only a faint response. I recalled that in our Medina home office I frequently heard the girls listening to the dictaphone when it could be heard plainly several feet away from them; and I knelt down as I told you, and asked the dear Lord to show me how to make the machine speak as plainly as it did back in my Medina home. Some of you may feel inclined to smile at my faith that my prayer would be answered. Perhaps I can make it sound a little more reasonable to you with this explanation. After having *prayed* over things I often seem to be impressed to examine more thoroughly in certain directions that I had failed to notice critically before. After getting up, or as soon as I arose, I felt impressed to get Huber's letter of instructions, and go over it a little more carefully and see if I could not find some clue to the trouble there. I saw now almost at once where he told me to pull a certain lever over toward me when I wanted to dictate. Now, as this lever could not come over toward me because there was a steel post or stud in the way that seemed immovable, I concluded that he must have made a mistake, and he meant to push it *from* me instead of pulling it toward me. At this time, however, I grasped hold of that little steel post once more, and finally found that I could turn it around; and after pulling a little harder I found it slipped back out of the way. Mrs. Root came over just at this time, and I told her we might rejoice, for my troubles were over. She replied, "Are you very sure?"

"Yes, I'm sure that my prayer is answered."

Once more I started up and called out "Helloa! helloa!" and the response came like an echo so plainly that it could be

heard all over the room. Through the dictaphone I thanked God for having delivered me out of my troubles, and finally ended by singing an old favorite hymn. I am going to give you one verse right here of that old hymn, dear friends. I wish it were *possible* for you to hear my voice as well as read the words in print. Perhaps it will be possible in time to come, as our good friend Edison is just now at work on something quite similar.

Oh to grace how great a debtor
Daily I'm constrained to be!
Let thy goodness, like a fetter,
Bind my wandering heart to thee.

The words came back full and clear, and seemed like a benediction.

Two or three years ago our people in Medina sent word to me, while down here in Florida, that they wanted me to employ the best artist I could find and get a good picture of myself to be put into GLEANINGS. I kept putting it off, but finally they urged so that I went to work to get a disagreeable duty off my mind. First, I went to a good barber and told him I wanted him to take plenty of time and fix me up in the best style he could so that I could have a picture taken to put in print. He was an *Englishman*, and was (therefore?) in the *habit* of doing good and faithful work. Then I went to the photographer and told him something the same thing. He took, perhaps, half a dozen pictures, and then touched them up with all the skill he possessed, and submitted one of them to me for my approval. Now, I was greatly rejoiced to find out that he had made a real good-looking man of my poor old self. In fact, it was so much better looking than I am really that my friends and relatives all said that it didn't look like me, and on this account it never was given in GLEANINGS; but I always felt bad about it. May be I can give it to you yet if some of you care enough about the matter.

But now in regard to the dictaphone. Mrs. Root declared right away that it was beautifully clear, but that the voice didn't sound like mine at all, and I agreed with her. I told her that I should never know that it was my voice. In fact, I never before was aware that I had a voice of so much volume and strength. Now please, dear friends, don't think me presuming or puffed up when I say that, after the kind words which have come to me all these years from the readers of GLEANINGS in regard to my allotted work in this world, it occurs to me that it might be a pleasure for the readers of GLEANINGS to hear my voice. Well, I don't know just how it is going to

* There is also a period in the wrong place on p. 67, toward the close of the page. Instead of "He applied to the Savior again and again," it should be, "He applied to the Savior again. And again the Master," etc.

be brought about; but I have faith to believe that the time is coming when God will give us the means of talking to friends thousands of miles away, great numbers of them; that he will also give some invention to enable the readers to hear the tones of our voice when they are reading the printed words. This thing has already come to pass to a certain extent, for I suppose you are fully aware that these cylinders can be shipped thousands of miles, especially if they are carefully packed, and enable friends not only to review the words of all those we have read about and loved, but also to hear the very tones of voice of people who have been long years dead and laid in their graves. "Rejoice! May the Lord be praised for the victories of men."

Let us go over briefly the overcoming of difficulties before I could talk to you as I do now through this beautiful instrument. First, the order to ship it to my Florida home was overlooked or neglected. Second, after it was shipped the agent here at Bradentown kept telling me "Nothing for A. I. Root." When it finally came, there was no mouthpiece with which to dictate; and the carriage failed to move. When, after hard work and earnest prayer, I succeeded in overcoming this trouble, the machine wouldn't talk plainly and clearly. Finally, in answer to my prayer, I discovered that the little steel post that seemed to be riveted so firmly *could* be lifted back to let the lever come forward. Once more, in my triumph, after I succeeded in making it work to perfection, and had used up the cylinder in thanking and praising God for the victory, those cylinders were smashed by the express company in its transit to Medina. Perhaps I was somewhat at fault in my method of packing; but I had large printed labels pasted all over the package, saying, "Fragile, handle with care." The express agent or handlers, however, seemed to pay no attention to this caution.* Both of the first two packages were smashed and rendered almost useless. After we got it working so finely, Mrs. Root suggested that perhaps there was a *providence* in it after all; for had not all these troubles occurred I would not have been obliged to pull the machine all to pieces and study its construction so fully, so that now I was perfect master of every detail of the complicated apparatus. Yes, this is true; and this trying experience I have had is probably worth much more than all it cost. But now, dear

friends, comes a much greater and grander truth. In praying that I might have the wisdom to surmount the obstacles that lay before me I came into closer touch with my Savior than perhaps I had ever been before. In fact, for several days afterward it seemed as if a new companionship was with me, and by my side, no matter what I was doing. Scripture texts came to me in great numbers that I had never particularly noticed before, and seemed to shine out with a new and wondrous promise. I presume this experience will not only give me more faith, but will, perhaps, make the Bible promises brighter, many of them, for the rest of my life. For instance, I recalled the time when the disciples were worried because they thought the Master was reproving them for forgetting to bring bread. In one of our texts I have recalled the circumstance. He remonstrated with them for not having *remembered* how he fed the multitudes with the loaves and fishes, and for not remembering that all the resources of this *great universe* were at his beck and call. The man, woman, or child who has no difficulties or trials to overcome can never *arise* to his *fullest* and *greatest* and *grandest* development. "To him that overcometh I will give to eat of the tree of life, which is in the midst of the paradise of God."

POULTRY-KEEPING ON OUR CONVERGENT POULTRY-RANCH IN FLORIDA.

When we arrived here the first week in November my first work was to get our fifty pullets from my neighbor Abbott and install them on our place. The pullets remembered their old home of six months before, without question; for, the very first thing, they sought out their familiar scratching-places and places to roost, watering-places, etc. As they had scarcely finished moulting, for a few days we got very few eggs, perhaps only three or four to start with. As eggs, however, were forty cents a dozen the pullets very soon began to pay for their feed. At the present time (first week in January) we are getting from fifteen to twenty eggs. I might remark right here that eighteen ducks have given us about as many eggs as fifty pullets so far; and as the ducks get a large part of their feed from the canal I have spoken of, they are more profitable than chickens so far. With the fifty pullets was a three-year-old Buttercup rooster. He, too, was in the midst of a moult. I suppose it is not very good management to expect a three-year-old rooster to give eggs with very high fertility when given as many as fifty pul-

*I notice the U. S. Express Co. furnishes its agents a good-sized label, reading as follows: "Glass: with great care. Put this upon every package of glass." Now, the agent who would deliberately ruin a package thus labeled should be severely dealt with.

lets. Somehow or other, I got into the way of reasoning that the male bird didn't try to serve any more than the pullets that were laying. He is very quick to single out a hen that laid an egg and serve her; but does he serve or undertake to serve the others that don't lay at all—that is, where he has a yard full of pullets? I have hunted the poultry journals for years in regard to this, but have never been able to find a single thing touching the subject. Some of you may remember that I paid one dollar for a secret for getting strong fertility. The secret was this: Fix your nests or gate so that, when a hen has laid an egg, she will go into the yard where the male bird is confined; and as he, as a matter of course, serves her promptly as soon as she comes into his "harem," you would naturally suppose that the eggs would be all fertile. Now, this secret seemed to take the ground that the male bird serves only the laying hens. Well, my first hatch from the incubator that holds fifty eggs was only thirty eggs fertile. Thinking the trouble was because moulting was so near, I tried it again, putting in sixty eggs* for the first five days until testing time. Although the hens were mostly over their moult this time, I got only thirty fertile eggs from sixty. As I can't stand this sort of work I divided my hens into two yards, and have put a brisk young Buttercup rooster in the other half, and we expect better fertility accordingly.

I want to repeat again that I do not believe artificial heat is needed here in our Florida climate for brooders. Fireless brooders properly arranged are certainly all that can be needed for twenty-five or more chicks. I have taken two broods this winter right out of our hot incubator, of course keeping them there about twenty-four hours after they were hatched, and put them directly in the fireless brooder. The second day they would be out running in their little yard, and scratching the bran and sand with which the ground was covered. The next day they were climbing over the sides of the yard and rambling all over the brooder-house. I have repeatedly proved to my satisfaction that artificial heat has a debilitating effect upon the young chicks when they

are able to get along without it. The convergent poultry-yards are proving such a wonderful convenience I wonder how it is that people who keep poultry have been so long without thinking or discovering or getting on to this short cut in the management of poultry and poultry-houses. Think of having the poultry-houses scattered over four or five acres where they can just as well be all in one convergent yard! When the little chicks grow, you can let them out further and further, finally giving them the whole range as far as the fences go. Just now we are building the fences out only as far as the chickens seem to run. As they grow older we build the fences a little further—no cross-fences from one side to the other at all. In this way they can have almost unlimited range, and yet all the feeding and caring for them is done at one central spot. They are all shut up at night in no time at all, compared with the old plan of chasing all around to so many different houses. This inner court where we keep our grain and all our utensils is shut up so that it is almost an impossibility for a rat ever to gain access. There are no mice here; but I am sure it would be an easy matter to fence out mice with comparatively little expense in the far North if this plan is followed. By the aid of a windmill we have dripping water and suitable vessels between every two yards, so that the water takes care of itself comparatively. When the watering-dishes need to be washed out it can be done very quickly, as they are all right at hand, and easily pulled out of place.

INSURANCE COMPANIES AGAINST THE DRINK HABIT.

Insurance companies in Great Britain, America, Sweden, Norway, and Germany are discriminating against those who drink, even in moderation. The insurance companies in Germany have issued leaflets and posters showing the detrimental effects of alcohol on the human body. Many insurance companies place total abstainers in a separate division, insuring their lives on cheaper rates. It is manifestly unjust to require that total abstainers shall pay higher insurance rates on account of the losses caused by the drinkers insured by the same company. The discovery of science, that alcohol is a life-destroyer, is arousing many who heretofore have been uninterested in the temperance problem.—*Union Signal*.

Editor American Issue:—Some things you can send through the mail by parcel post are: Eggs, butter, meat, medicine, fruit-trees, oils, ink, candy, milk, or queen bees. Some things you can not send: Obscene literature, poison, snakes, explosives, infernal machines, pistols, disease germs, or intoxicating liquors of any kind. At last the government has made a wise and proper distinction. They are all of a kind.

L. R. H.

I wonder if L. R. H. isn't a beekeeper. Sounds like it.—A. I. R.

* Perhaps I should explain again how I get sixty eggs in a fifty-egg incubator. I do it by standing them on the small end for the first three days. With our bright Florida sunshine I can test them quite easily at three days, and Mrs. Root now agrees that such eggs, as a rule at least, are just as good as any three-day-old eggs for any purpose whatever; but, of course, we never sell them. Since dictating the above I have made two yards of my 50 hens, with a good male in each, and now I get about 50 fertiles out of the 60 eggs. The mother duck with her twelve ducklings flies over the two-foot fence every day, takes a swim in the canal, then comes back, and is a "model mother," even if she is an I. R. duck.

Editorial

No one can say, now, that women do not make good beekeepers.

THE NATIONAL CONVENTION FEB. 12, 13.

THIS was held at the Grand Hotel, Cincinnati. While the attendance was not large it was representative. At the first session it looked as if there might be an "irrepressible conflict." The delegates present were not agreed as to the best policy to pursue. But all is well that ends well, for the points of difference were referred to a committee, and the reports of this committee were finally agreed to. A brief report will be given later, together with a half-tone view showing the members and delegates present.

FEEDING HARD CANDY TO BEES.

WE have been giving paper pie-plates filled with hard candy to some of our colonies that seemed to be running a little short, for the last three months. This candy is made of twenty parts of sugar to one part of honey, the whole moistened with water enough so that it can be boiled. It is then heated to a temperature of 275 degrees Fahrenheit, and as soon as it reaches this point it is poured into the pie-plates mentioned. These are turned upside down right over the cluster, and so far they are giving excellent results. They are not affected by moisture, as Mr. A. C. Miller feared would be the case. Indeed, they preserve their shape perfectly, even when empty. As this winter has been somewhat open in most localities, there is danger of starvation.

Soft candy may be as good. We have tried it to some extent, but prefer the hard.

BEES ESCAPING FROM A BROKEN PACKAGE
MADE TROUBLE AMONG POSTAL CLERKS.

As we have intimated before, we have feared that some one not acquainted with the difficulties would attempt to send bees by parcel post, and that the cage would be broken and trouble be made at once. This is exactly what has happened. Just as our editorial form for the last issue was going to press, as mentioned briefly on page 106, we received a clipping from the San Francisco *Chronicle*, of Monday, Feb. 3, telling

of a lot of bees that took possession of a postoffice at San Rafael, on Feb. 2. Particulars were not given, except that, when the postal clerk opened the parcel-post pouch, the bees flew out of it, and stung him on the face and hands. The box in which they had been confined was smashed in transit, giving the bees the run of the mail-pouch, and, later on, of the postoffice.

As stated in our last issue, there seems to be no provision, at present, authorizing the shipment of bees by parcel post; and if the careless experiments along this line do not cease, there is danger that bees may be altogether barred from the mails, thus bringing about a serious state of affairs for queen-breeders and beekeepers as well.

IN MEMORIAM OF D. H. COGGSHALL.

It seems but a few weeks since we spent a very pleasant half-day with Mr. D. H. Coggsall the last time he was in Medina. We had met him several times before at conventions, but we became much better acquainted with him at this time, and it was with a shock, therefore, that we learned of his very sudden death as mentioned in our Feb. 15th issue. It seems that our friend had made all preparations for spending the winter in Florida, as was his custom. His home west of Groton had been closed for the winter, and every thing had been arranged for a long absence. How little anybody thought at the time that these preparations were then made for the last time, and that the departure was a final one, the return to the home-place to be only after death!

The party, consisting of Mr. and Mrs. Coggsall, and their daughter and her husband, Mr. H. J. Blanchard, had already left Groton, and had proceeded on their way south as far as Sayre, Pa. While waiting for the connecting train for the South at the Lehigh Valley station, Mr. Coggsall died very suddenly of heart failure. He had anticipated another pleasant winter at his southern home at Stuart, Fla., where he had spent every winter for eight years.

Mr. Coggsall was born Dec. 1, 1847, in

Groton, in which township he made his home all his life. He was a brother of W. L. Coggs; and although the latter has always been known as one of the most extensive beekeepers in the world, his brother was also extensively engaged in the business, having had at one time 800 colonies.

Although a quiet beekeeper, our friend was a progressive one, and we feel that the apicultural world has lost another pioneer. He was not a frequent contributor to the bee journals, and yet he will be missed—missed most by those who knew him best.

THE RELATIVE FOOD VALUE OF HONEY AND SUGAR-SYRUP STORES FOR BEES.

ELSEWHERE in the Canadian Department Mr. Byer makes the assertion that honey is superior to sugar stores, and then puts the proposition up to the editor.

During the 70's or 80's, we do not remember exactly when, R. L. Taylor, James Heddon, Prof. A. J. Cook, and, we believe, W. Z. Hutchinson, all of Michigan, each independently of the other, made some tests as to the relative value of sugar syrup and honey for wintering. The testimony of all the men, if our memory serves us correctly, was to the effect that, pound for pound, sugar syrup was much to be preferred to ordinary honey, and very much better than the ordinary dark or off-flavored fall honey. We had supposed that the whole beekeeping world had accepted this as a fact. For brood-rearing purposes honey has a slight advantage, because practically all honey contains minute quantities of pollen. In fact, Professor Brown, of the United States Bureau of Chemistry, once said that the source of many honeys is recognizable by the pollen grains when viewed under a microscope.

The primary reason for preferring sugar syrup is that it is less stimulating. A farinaceous diet on the other hand has a tendency to make the bees active when they ought to go into their winter sleep, or, as we say, into a semi-state of hibernation, or what amounts practically to suspended animation. In that condition respiration is low and the consumption of stores light. Sugar syrup of course has no pollen in it. It was shown in the 80's that the bees would eat anywhere from 10 to 50 per cent less of sugar stores than of natural stores during the winter, the percentage of variation depending on the quality of the honey. We do not go so far as to say that the presence or absence of pollen contributes to poor or good wintering. But when we come to draw the line between the two foods, the almost universal verdict has been in favor of sugar

syrup. On the other hand, it is generally considered that it is not necessary to extract good honey and feed sugar stores unless the difference in price between the two products warrants it. The extracting and feeding have a tendency to stir up a colony. Feeding in the fall with sugar or honey, especially if the queen is a young one, has a tendency to induce brood-rearing. Sometimes this is desirable, and sometimes not; so when we come to consider the relative food value of sugar and honey there are several factors to take into account.

Friend Byer, practically in opposition to all the rest of the fraternity, makes the statement, "I now *know* that at the very least it takes a pound of sugar to have that value." "That value," as we understand it, is a pound of honey. We do not say he is wrong, but we should like to have him present his proofs. Our correspondent's opinions we value; and when he challenges the editor and perhaps all orthodox beedom he is entitled to consideration.

A TRAMP BEEKEEPER SPREADING BEE DISEASE; AN AGGRAVATING CASE.

A MOST exasperating case has come to our notice of a certain tramp beekeeper, who, it is alleged, is moving bees by the carload from infested districts into localities where no disease exists. He seems to have no scruples about squatting an apiary of bees infected with European or American foul brood next to a healthy yard belonging to a permanent resident. When the locality becomes so rotten that even *he* can not stand it he moves to new territory, there to repeat his nefarious work. He practices migratory beekeeping on quite an extensive scale; and as he goes from one locality to another, it is said he takes no precaution to eliminate disease from his own bees; is careless about leaving tools and appliances, daubed with honey, after extracting, where all the bees in a locality can get at them, and thus carry the infected honey to their own hives. Numerous complaints have come in from beekeepers where he has been operating. Evidently nothing can be done, because he violates no law. He squats in localities where there are no foul-brood laws, or else where the laws are so carelessly drawn that he can not be restrained. It is claimed that he is spreading bee disease right and left: that he even *jokes* about it, saying that bee disease is his best friend, because he can go into a locality and clean out every beekeeper who may be a natural competitor. How is that for unadulterated meanness? Can you beat it?

It is high time that States in the West

that do not have foul-brood laws should secure the necessary legislation at once. Unfortunately, California is handicapped by a very ineffective *county* law. These county laws are not worth much at best. What is needed is a law that gives the State Entomologist or State officers police authority *over the whole State* to clean out bee disease wherever it may exist, and at the same time put a stop to the kind of work above described. A federal law should be enacted at once; for unless something is done speedily, such tramp beekeepers can spread more disease than all the inspectors in the country can eliminate.

"THE MANIPULATION OF THE WAX SCALES OF THE HONEYBEE."

THIS is the title of a new bulletin from the Bureau of Entomology, Circular No. 161, by Dr. D. B. Casteel, who has been in the Bureau for the past two summers, pursuing various kinds of work under the direction of Dr. E. F. Phillips, in Charge of Apiculture. We have read carefully this bulletin, and regard it as one of the most interesting and valuable that have ever been put out by the Bureau. We say it is interesting, and it is intensely so; and valuable, because there are certain facts presented which may enable the ordinary beekeeper to determine when he can have comb building, and when, perhaps, he may not.

About 35 years ago the writer was interested in this very subject covered by Dr. Casteel; and especially how bees put pollen in their pollen-baskets; but at that time we were not in possession of the apparatus, the time, nor the skill necessary to do this work. We watched the operation, or tried to, whereby the bees remove their wax scales; but it was done so rapidly that the whole performance seemed but little short of sleight of hand. Somehow the scales would be removed from the under side of the bee's abdomen, and transferred to its mouth; and likewise pollen would be transferred from the fore feet to the hind legs; but just how, we could not determine. But Dr. Casteel has worked this out by means of a binocular microscope that makes every detail of it, from start to finish, clear and plain. He then goes on to prove up his work from a purely mechanical and structural point of view.

Briefly stated, the process is this: The wax scales are scraped off by one of the large joints, or planta, of one hind leg, the spines of the planta piercing or catching into the scale; then the leg, by a peculiar maneuvering, is moved up to where the fore legs may grasp the scale. At this

point of proceedings the scale is manipulated or masticated in the mandibles, when it is applied to the comb. During the process just explained, the bee stands on three legs (the two middle legs on either side, and one hind leg not in action), while the other hind leg and the two fore legs, in connection with the mandibles, perform the manipulation. The whole thing is shown by some elaborate and careful drawings. We hope to have the privilege of presenting some of these later on in these columns.

Dr. Casteel shows that the so-called "wax-pinchers" in the hind legs have nothing to do with the manipulation of wax, but are designed for another purpose, and that each individual bee removes its own wax scale.

It has been popularly supposed that the bees remove the scales from each other; but the author shows that this is not the case. The scales are sometimes found scattered throughout the hive and on the bottom-board. In some instances they show the marks of the spines on the planta of the hind legs. In others they were probably dropped accidentally by the bees in that wonderful sleight-of-hand performance of which we have been speaking. In still other cases the scales show no markings whatever, and the presumption is that they simply fell off the bees when they reached a certain stage of development.

Dr. Casteel also confirms the observation of Dreyling, that there are certain ages and certain seasons when the bees will develop these wax scales more than others. From this it would appear that there will be times when bees could not construct combs to any great extent, even though they were liberally fed. In a practical way it has been found that sometimes even when the bees are fed they will not build combs; and the probabilities are that they simply can not, because the colony is made up of bees too young, too old, or both. Usually the condition of a honey-flow can be supplied artificially by feeding.

This paper or bulletin may be obtained by simply addressing the Superintendent of Documents, Government Printing Office, Washington, D. C. Ask for Circular No. 161, Bureau of Entomology, by D. B. Casteel, and enclose 5 cents. We hope our subscribers will ask for it, as we should like to have the Secretary of Agriculture, or, more exactly, the Bureau of Entomology, know that the beekeepers of the country appreciate this kind of work.

In our next issue we shall refer to another bulletin equally interesting and valuable by the same author on the subject of how the bee gathers pollen.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

DR. E. F. PHILLIPS made a short visit with us lately. Just now he is trying to learn what instruction to give the bees for best wintering in cellars. I practiced cellaring bees before Dr. Phillips was born; but he gave me points on it that made me open my eyes.

DAVID ROBERTS says, p. 116, "Shelter is not conducive to swarming except so far as it favors brood-rearing." Doesn't the kind of shelter have a bearing? The shelter of an apple-tree tends to prevent swarming. The shelter of buildings, bushes, etc., on all sides, preventing a free circulation of air, tends to favor swarming by making the bees too warm.

J. E. CRANE, I think you have things straight about European foul brood, p. 84, and it might also be added that a change of queens would be helpful, even if the new queen be not an iota different from the old one; but when a new queen is introduced there is nearly always at least a little break in brood-rearing, and that helps the bees about cleaning up.

"In 1896 Bradstreet's compilation of the wholesale prices of 106 commodities, including all the leading commodities of commerce, was 59,124; in 1900 this figure had risen to 78,839; in 1905 to 80,987; and in 1912 to 90,362."—*Daily*.

Let us see how the price of honey compares with this. Take quotations for comb honey, Sept. 1, in each of the years named, and find the average of the highest figure in each market. In 1896 it was 13.3 cents. If the advance in honey was the same as in the 106 leading commodities named, then for the years 1900, 1905, and 1912, respectively, it should be 17.7, 18.2, 20.3. It was 16, 13.9, 17. Take extracted in the same way. In 1896 it was 6.6 cents. In 1900, 1905, and 1912, respectively, it should be 8.8, 9, 10. It was 8, 7.2, 9.4. No doubt other factors have a bearing, which might make the showing better or worse; but in a general way it would seem that honey has not climbed with other commodities. [This is interesting in more ways than one. It shows that the price of honey declined from 1900 to 1905, and from that time on, especially beginning with about 1908 or '9, prices on food began to soar. This onward and upward tendency advanced the honey market at the same time, but not in proportion, as it would appear, to the price of other food stuffs taken as an average.—ED.]

"ONE-POUND section" is a term in common use; yet, strictly speaking, the one-pound section is a sort of myth, for not often is a section found which weighs 16 ounces, said section being $4\frac{1}{4} \times 1\frac{7}{8}$, which is the section mostly in use. For years there was more or less dishonesty about these sections, for grocers too often sold them as full pounds. Now, however, the public is better informed, and there is not so much trouble on that score. Custom, however, varies, and in some places honey is sold by the section and in other places by the pound. Our honey quotations are given by the case, also the pound. Is there any likelihood that, in the near future, there will be uniformity in this regard? Will the Cincinnati convention dare tackle the question? There is a gradual increase of quotations by the case. Is that really the better way? and if so, can it be made the uniform way? [Yes, it is true that the one-pound section, strictly speaking, is a misnomer. To get a section of that weight $4\frac{1}{4}$ square would make it necessary to have it 2 inches wide for the combs to average one pound. This makes a comb too thick to insure quick ripening and quick sealing. A section $4 \times 5 \times 1\frac{3}{8}$, plain, comes nearer to a pound; but to *average* a pound it would have to be $1\frac{1}{2}$ inches wide. A relatively large thin comb is far better than a small thick one. This is one reason why the 4×5 size is crowding the $4\frac{1}{4}$ square out of some markets. We believe the time will come when it will be the universal section.

From every point of view, we believe it is better to quote sections by the case rather than by the pound. Under the Colorado grading-rules this insures a more uniform weight of sections. It compels the producer to aim for a higher standard, both as regards weight and filling; and this is right. If the cases are sold by the pound, it has a strong tendency to let in any bulged or fat sections that are unsightly, as well as those that are lean and unsealed. Under the Colorado rules, the sections must not weigh more than a certain minimum nor more than a certain maximum. If the producer will "separator" or "fence" his supers, and use full sheets of foundation, he is usually able to meet the conditions of the grading rules. We are, therefore, strongly in favor of selling by the case, providing the individual sections are graded according to the Colorado rules. If they are not so graded, the cases should have minimum weight.—ED.]

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

Some of our Ontario chaps have gone to California for the *winter*; and judging by that picture on page 83, Feb. 1, they seem to have found what they went after.

* * *

The "short course" recently held at Guelph was pronounced a success by all who had the good fortune to be present. The writer was there for only two days, but that was long enough to convince him that the students were satisfied that they were well rewarded for their time and expenses. Mr. Clark, of Borodino, gave a series of lectures on queen-rearing, while a number of Ontario men assisted in the lectures and discussions. Among them were Messrs. Sibbald, Armstrong, Nolan, Anguish, Schrenck, Bainerd, Harkness, and a number of others well known to the fraternity.

* * *

Dr. Miller says on page 790, Dec. 15, that a temperature of 32 to 35 degrees would be considered ideal wintering, even if there were no flight for four or five months. While we shall never have the privilege of proving the matter one way or the other, I venture to say that wintering would not be every thing desirable under such conditions, as the bees would be more or less uneasy all the time, and consume stores and go to brood-rearing—in the end would not come out as well as though the temperature had been much lower than that during most of the time the bees were confined. Bear in mind this is just my *opinion*, and I make no promise to try to *prove* the thing one way or the other.

* * *

Regarding the matter of sugar syrup versus natural stores, page 790, I am surprised when the editor says that reports for many years back have shown that a given amount of sugar syrup will go further than the same amount of natural stores. Surely you do not believe that a pound of *syrup* will go as far as a pound of good honey. While I have to feed lots of sugar syrup some falls, certainly I do not place that proportionate value on the syrup as compared with honey. I used to *think* that a pound of syrup would equal a pound of honey in so far as lasting qualities are concerned; but I now *know* that at the very least it takes a pound of *sugar* to have that value. Emphatically, I again say that, if your colony is short weight 15 pounds, instead of giving that amount of *syrup* to make the colony equal to the one heavy enough with honey, use at least that many

pounds of *sugar* instead, and then see in the spring if the syrup-fed colony is ahead of the one wintering on the same weight of honey. [See editorial comment elsewhere. —Ed.]

* * *

I never knew a season in which there has been such a demand for honey as the present one. Whether the consumption is increasing or the last crop much shorter than we estimated, one thing is certain: Many thousand pounds of honey could have been sold during the past three months if we had had the goods. Only recently a very responsible firm asked me to send them *at once* 14 or 15 thousand pounds, and I was unable to send them that many hundred pounds, let alone thousand. Some think the shortage is too short, even from the producer's standpoint, as it is feared that, being unable to get honey at a reasonable price, they will try to get a substitute to take its place. While I do not fear that very much, how I would have liked to fill that order for 15,000 pounds!

* * *

The vagaries of the weather are hard to explain; for while the conditions have been unusually cool, not to say cold, in the far West, here in Ontario the months of December and January were much milder than usual. Since February we have had some winter weather, but at no time this month has the thermometer gone below zero. Only twice this winter have we had a zero temperature; but as we have no snow the conditions are not any too good for the clover. However, the months of March and April generally decide the clover question. Only once have I known damage to be done in February. This mild winter should be good for outdoor wintering; and, barring one single report to the contrary, all who have written me say that the bees are wintering well. A number have told me that their bees in regular house cellars have been uneasy, as it has been difficult to keep the temperature low enough. On getting these reports I wrote to a friend who lives near my bees, some 200 miles east of here, asking him to go into the caves for the purpose of seeing how the bees were. He reported that they were perfectly quiet, and seemed to be wintering in splendid condition. This would lead one to believe that the repositories almost if not entirely under ground, roof and all, are to be preferred to regular house cellars where the air is more apt to be subject to outside conditions and variations.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

CONCERNING COUNTY COMMISSIONERS.

Bills for bee inspection are presented to the county commissioners before they are allowed to be paid by the treasurer. The average county commissioner knows almost nothing of the character of the work of a bee inspector. If the county officers knew the character of the work to be done there would be little questioning as to the value of the inspection, and there would be more questioning as to the actual work accomplished. The county commissioners should require a detailed account of the apiaries inspected, number of colonies examined, number of colonies diseased, number treated by the bee owner, and the percentage of decrease in the disease from year to year. Bee inspection is a farce unless money enough is available to give thorough inspection of all the bees in infected areas; and it is still more a farce unless the inspector forces the cleaning-up of every diseased colony.

* * *

PAY TAXES ON YOUR BEES.

Patriotism of the simon-pure variety is shown in honest tax schedules with nothing legitimately taxable reserved from entry. The bogus kind is found where tobacco smoke is thickest in the political meetings where they "whoop 'er up" for the party that saved the country from destruction. The bogus kind always does the loudest clapping when the picture of Washington or Lincoln is thrown on the screen, or the flag is unfurled. If we appreciate good roads, schools, and progressive public enterprises, we should consider it a privilege to contribute our share to the public welfare. And if the public funds are being misappropriated we should be just as loud in our denunciation and active in righting the wrong as is possible; and for the bee-man to pay his full share of taxes will give him the right to ask and demand full protection from his county, State, or national government in the way of bee inspection.

* * *

TINKERING WITH FOUL BROOD.

Out in Idaho there are still a few beekeepers who cling to the idea that American foul brood can be cleaned out of diseased combs with formaldehyde. Those who still hold this idea certainly have not tried it thoroughly. Our experience with fumigating combs was quite extensive and thorough; and while the disease did not reappear in every comb so treated at once, every

comb showed the disease as prevalent as ever before the season was over. For the average honey-producer to attempt the experiment is folly. It may be possible in time to find a method of fumigation that will kill the disease; but the beeman will make money by leaving the experimentation to the experiment stations. Follow the known methods, and work your diseased combs into wax. Get the wax worked into foundation, and put full sheets in your brood-frames, and you will lose scarcely any thing but the work.

HOW TO GATHER SWEET-CLOVER SEED.

A device was illustrated, p. 454, July 15, 1912, called a sweet-clover-seed stripper; so, wanting to gather some seed, I made one which was similar. It would not work satisfactorily, so I placed in the center of the large sheet made out of several old bed-ticks, a large box. Over this box the sweet clover stalks were thrashed in convenient-sized handfuls. The larger part of the seed falls into the box; but what falls outside can be easily gathered from the sheet. The seed then requires sifting through a screen of about a fifth-inch mesh to take out the sticks and leaves. The seed will not sift through ordinary window-screening, as the unhulled seeds do not readily pass through. By rubbing hard a considerable amount will hull out, but the leaves are ground into a fine dust by so doing. Sweet-clover seed should be run through a fanning-mill in order to remove this dust.

CUTTING THE CLOVER.

The seed rattles off the stalks better if it is ripe before thrashing. To prevent the seed rattling off while cutting the clover, select a time after a damp period or a rainy spell. The seed will not rattle off so much if cut just before it turns brownish black. The seed will ripen if cut and laid on the ground in piles.

A scythe is not to be recommended for various reasons. Much of the seed is lost; and, besides, it is difficult to work even a brush-scythe on the coarse stalks. There is a chance that weed-stalks will get in with the sweet-clover stalks, and this should be avoided.

The best method is to cut the stalks by hand with a sickle, piling it up as cut. A half-acre of sweet clover furnishes me 350 pounds of fine seed. The work of gathering the seed required about five days, every thing counted.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

How would this sound—cellar wintering in California? Not as strange as it would have sounded at one time.

* * *

While Editor Root, Dr. Miller, and Mr. Byer are sparring over the question of how bees winter on solid combs of honey, the most of us are wondering how they ever reached the winter with so much honey any way.

* * *

When I read the letters of those old-timers who were subscribers to GLEANINGS shortly after I was born I feel quite young; but when I stop to think that I myself was a subscriber back in the eighties I feel that I am getting old fast enough.

* * *

FEEDING UNNECESSARY IN THE SPRING IF
THE COMBS ARE ALREADY WELL SUPPLIED
WITH STORES.

After stimulating some of my colonies for three weeks with sugar syrup I opened them in order to see the results of my kind care, and was gratified to find much brood started. Curiosity led me to open some others, and they had as much as or more than the ones I had been feeding. I doubt if there is much gained by feeding a normal colony that has plenty of stores, for the purpose of inducing them to rear brood. Pollen is a greater aid in that direction, and more to be desired, than additional stores. A weak colony short of stores would doubtless be encouraged to more liberal use of its meager supply of stores if there were more coming in daily; but where stores are no object one must look to other conditions to induce brood-rearing, and nothing is better than a supply of pollen adequate for each day's use.

* * *

PROSECUTION WARRANTED IF DISEASED COLONIES ARE SHIPPED WITH FULL KNOWLEDGE OF THE OWNER.

Mr. Wesley Foster, Feb. 1, answers my query as to whether a carload shipment of bees that were prevented from being shipped into Colorado were known to be diseased. For the most part I like Mr. Foster's answer; but on one or two points I wish to make a suggestion. He says, "Our Colorado law is broad enough so that I think an inspector would be upheld in destroying all diseased bees upon arrival. This would not be just unless the disease was being introduced into a clean district." I will agree

with Mr. Foster that, in a case of this kind, stringent means should be resorted to; but at the same time I do not believe that a man's property should be destroyed for the benefit of society unless society is willing to compensate for its loss; for to throw the burden on the individual when the benefits are enjoyed by the entire community would be manifestly unjust; and it seems to me poor law also. The same would be true anywhere. I have opposed the destruction of bees, diseased or otherwise, where they were shipped in good faith as being free from disease, but were later found to be diseased. If it is found necessary to destroy, there should be some compensation for the loss unless they were shipped with the knowledge that they were diseased. Then I believe they should not only be destroyed, but the shipper should be vigorously prosecuted.

* * *

PROSPECTS FOR HONEY.

Conditions in California seem to have changed for the better. We have just had another inch of rain, which helps to add new hopes at least. Indications now are that there will be sufficient orange bloom to supply those who are depending on it for their main flow. I have given the sage very close inspection, and find that some of it is damaged beyond my greatest fears, while much of it is injured less than I had supposed. The situation in this locality is about like this: In the small valleys and bottoms of the canyons the bloom is not only killed, but much of the wood (at least that part of the wood from which the bloom comes). On the sides of the canyons there are increasing signs of life; but the signs are deceiving at this point; for while there are plenty of green leaves on the twig-tips, the bloom-buds within are dead. As we go on up the canyon sides the green increases rapidly, and a point is soon reached where there is no indication that there had ever been a freeze. This condition rules, no matter how small the canyon or what the elevation, and is only in keeping with the old and well-known fact that the cold air holds its position below the warm, hence the frozen and dried tops in the little valleys and the bright green higher on the canyon sides. It is really remarkable to see how well defined these lines are shown by the green and the lack of it. Forty or fifty feet up the canyon sides, above bushes that are brown and dried from frost, there are bushes that seem never to have been touched.

Conversations with Doolittle

At Borodino, New York.

LONGEVITY OF QUEENS.

"Am I right in thinking that all improvement in bees must come more largely through the queen than otherwise, inasmuch as one can have no certain control of the drone? and in order to be sure of being on the right track when working for long-lived bees, should not the mother of these bees be long-lived also?"

"Yes, I think so."

"But if this is the case, how does it happen that nearly every queen-breeder as well as the majority of our most prominent beekeepers advocate that no queen be allowed to live more than two years? Many are advocating the superseding of all queens at the close of the honey-harvest after their first year's work."

"This is something which has puzzled me as well as you; and I never could see how any great improvement of stock would result in any apiary where new queens are reared each year or two to supersede all those reared one or two years before. I have noticed many times that such colonies as kept the hive populous during the summer months with brood to the amount of only five or six Langstroth frames full, and stored the most honey, always had queens which lived, when the apiarist allowed them to do so, to a good old age. But the trouble has been that most beekeepers have had prolific queens so drilled into them that no queen that will not produce brood in excess of this is not allowed to pass her second winter. And because of this, the goose which laid the golden egg has no chance to prove her superiority above the rest. Queens which live to be four or five years old give to us our starting-point when breeding for the bees which make the greatest amount of honey with the least expenditure in bee force and brood-rearing. Much honey is used by *scrub colonies* in rearing a multitude of larvæ from queens whose average usefulness does not exceed a year and a half or two years. And these long-lived valuable queens, with hardly an average amount of brood, are the ones sure to be killed by the beekeeper who tells us that, if we would have the best results in hives full of brood, all queens must be superseded after their first or second year of laying."

"But would you recommend rearing queens for the improvement of stock from a mother which is four or five years old?"

"In regard to rearing queens from such an old queen, I do not claim that a queen is better at that advanced age than she is

when younger. Only this: I am not *sure*, at a *younger age*, that she possesses the desired longevity. Where any queen from a long-lived strain of excellent workers has lived to an age of five years I expect that her posterity, both workers and queens, will be remarkable for longevity as well.

"A good guess can be given regarding what young queens will prove to be as to length or shortness of life in two ways. First, if during the first half of the first month of May in which a young queen lays it is found that the colony of a young queen is building up while others are dwindling (all colonies, of course, having had the same protection and stores during the winter, and being equally strong at the beginning of the season), then one would not be far out of the way if he concluded that those building up have queens and bees with a promise of long life, while the others do not have queens fit to become breeders.

"Second, after a young queen begins to lay in a full colony, and after the swarming season is over, if a frame is put in such a colony having a starter of worker comb foundation in it, then, if the frame is filled with worker comb, I consider this queen worthy of further testing. If drone comb is built I do not expect much from her beyond the first or second year."

"But don't you think that there are other influences which tend toward longevity?"

"Surely I do. But, as I hinted before, the *queen mother is the starting-point*. The worker larvæ as well as the queen larvæ must be properly fed. Undoubtedly you have noticed that some larvæ as soon as hatched are fed much better in some colonies than they are in others. I have seen larvæ in the colonies of my best queens which were fed so abundantly that one might suppose that royal jelly was being given them. They actually floated in their creamy food until almost, if not quite, the fourth day. Other colonies are fed so sparingly that it requires microscopic vision to see that there is any food in the cells for the little six to twenty-hour-old larvæ to eat. It is needless for me to say that I do not consider these underfed larvæ fit to use under any circumstances for queen-rearing. Queens which will live four or five years can not be reared from such larvæ. Where such are nursed as queens (by a change of bees or different surroundings), their life is so restricted that from six months to a year is sufficient to find the bees themselves superseding them for something better."

General Correspondence

HOW A WOMAN MANAGES THE HEAVY WORK IN AN APIARY

BY MISS EMMA WILSON

[As most of our readers know, the writer of this article is Dr. C. C. Miller's sister-in-law, and his right hand man(?) in the apiary. Because of her long experience and training under such a teacher as Dr. Miller, we think that Miss Wilson deserves the title of "Dean of our Beekeeping Sisters.—ED.]

The question is no longer asked, "Can a woman successfully run an apiary alone?" It has been demonstrated too many times that she can and does, for there are many apiaries run entirely by women, and successfully too. But there is no denying that, in the running of an apiary, there is heavy work that must be done. How can a woman manage this heavy part of the work?

The experienced bee-woman has learned to take advantage of many little kinks that lighten her work, and knows, like the good general that she is, how to plan her work so as to accomplish what has to be done with the least expenditure of strength and labor. Especially is this necessary for the rather delicate woman who has no great amount of strength to spare.

To lift out a frame of brood, bees, and honey, and look it carefully over is quite easy; but to handle these frames at arms' length, or nearly so, gets to be work before night; and especially is this true before the muscles become accustomed to the work. So, begin by doing only a little at a time, gradually increasing the amount done each day.

When a colony must be moved, don't try to lift it all at a time. Take an empty hive and lift out part of the frames, putting them into the empty hive; then the rest can be lifted easily. Still, there may be times when it is desirable to move hives without opening them, as when taking in or out of the cellar. In that case it may be best to get a man to do the lifting. But if no man is available, possibly some woman can be found who will help; and if the hives have cleats on each end, the cleats running clear across the hive so that a rope can be slipped over them, you will find that two can carry a hive quite easily by each taking hold of the rope on opposite sides of the hive. An endless rope is used, and it can be quickly thrown over the cleat on each end.

The really hard work begins with the harvest, when there are so many supers to be lifted off (often four or five, and sometimes more), before you can reach the brood-nest; and when you go through your colonies every eight or ten days it means

work to lift these same supers off and put them all, or the larger part of them, back again, after going through the colony. But it makes some difference how the work is done. Instead of putting them on the ground, or leaning them against the hive, have an empty hive-body ready and pile the supers on that as you take them off. It is much easier to lift them from these than from the ground, and they will go back to the hive exactly in their previous order. Sometimes, however, it is desirable for some reason to change the order. Each super is inspected as it is taken from the hive; and any change in the order will be made as the supers are taken from the hive. Then when they are to be put back on the hive no time is lost in a second inspection. Another good thing about this arrangement is the immunity from robbers. When robbers are at all troublesome a robber-cloth can be thrown over the pile of supers, and they are safe, often allowing you to keep on working when otherwise you would be obliged to quit.

But if I were obliged to name just one item in saving hard work in the apiary it would unhesitatingly be—*keeping queens clipped*. I have not had a great deal of experience in climbing after swarms; but the little I have had has led me to believe that there is nothing more exhausting than climbing after swarms on a scorching hot day; and climbing after swarms will make any old day scorching hot. It is an exhausting, nerve-racking, temper-trying experience that, to my mind, is totally unnecessary. Of course, there will be an occasional swarm that may elude you, and issue with a virgin queen; but such swarms are the exception, and only serve to make you supremely thankful that you don't have to climb after every swarm that issues. Indeed, after one such experience, what bliss it is, when the next swarm issues with a clipped queen, to pick her up, cage her, lay her at the entrance, and nonchalantly walk away to attend to your own affairs and leave that swarm to do the same! Doesn't that sound alluring to those of you who still have unclipped queens, and are climbing after those dreadful swarms? Just try queens with clipped wings, and see if you ever want to go back to the unclipped ones again.

"Would be glad, too, if you could only do the clipping, but you can't." Oh! yes, you can—no trick at all after you are used to it. Just practice on a few drones until you get over feeling nervous about it.

You ask me, Mr. Editor, for something

new in the matter of women's bee-dress. Really I have nothing new to offer in that line. The only extras I don for the apiary are a large denim apron with two big pockets, gloves with sleeves attached, and a veil. The sleeves sewed to the gloves are white, and are fastened together in the back with a band between the shoulders, securely sewed to the top of each sleeve. A similar band fastens them in front, only the band in this case is sewed to only one sleeve. The other end of the band is furnished with a button-hole, and a button sewed on the other sleeve completes the fastening. This makes it easy to slip the gloves off and on when you wish to clip a queen. The veil is drawn down taut, and fastened with a safety-pin.

Marengo, Ill.

A WOMAN IN THE SPHERE OF ASSISTANT BEEKEEPER

MRS. LIZZIE SHIELDS

I can scarcely, as yet, claim to be a beekeeper; but my husband has started, and I help him. In 1906 a farmer whose cattle we pastured for the summer offered us in part payment a colony of bees which we accepted. They arrived in November, when, according to advice received, we dug a hole and buried them for the winter. The following May we found the hive afloat, and every bee dead—drowned by the melting snow. We steadfastly gazed on the bees that were dead, and bitterly thought of our lost five-dollar bill.

In 1907 the man again brought his cattle to pasture, and joined us in our lamentation. He said we should have made a drain to run off the surplus water. He wanted us to try again, and offered us a colony for half price. Again we agreed, and again put the hive in the same place; but this time we had a drain; and, lo! on bringing them out the next spring they were alive and in good condition. They were common black bees in an old box—very primitive indeed. We began to read and study about bees, and finally became enthusiastic.

We were unfortunate in 1910, expecting to winter three colonies. On moving them to the cellar, however, we found that two had decamped, root and branch, leaving only beeless hives with honey in them. So in the spring of 1911 we started again with a single colony. I purchased Mrs. Comstock's admirable book, and we also secured the A B C and X Y Z of Bee Culture. By and by, as a Christmas gift I gave my husband "Langstroth on the Honeybee." We purchased an Italian queen, and made a new colony from a nucleus. Ere long we

had a fine colony of Italians, and from them got a queen by which we Italianized the second colony. Meanwhile the second colony swarmed, and we had a third colony (blacks). We had 85 lbs. of surplus honey from our bees in 1911—practically from one colony, all the others being youngsters. These three colonies were wintered in our cellar, and were in fine condition last spring.

My husband took a short course in apiculture at the Ontario Agricultural College, Guelph, last January; visited the Brantford bee-supply factory with the other students, and left a fair-sized order for hives, foundation, excluders, etc., with the firm. On his return home he was saturated with bee lore.

Last June we purchased another Italian queen, and in September a third. Our three colonies have increased to six, all flourishing and strong.

We are now glad that we took heart and kept on trying. We find great pleasure in more ways than one. The honey is a good addition to our table, and we sell all we do not use.

Last summer the bees insisted on swarming, or otherwise demanding attention on three successive wash-days. My appreciation of their demands for attention was much below par. However, the swarms were little trouble to secure, as in each case we had clipped her majesty's wings, and so prevented her from flying off with her retinue. She had to content herself with walking on a white dress laid in front of the hive, where we quickly espied her, and carefully placed her in the new hive. In a very short time every bee found out that the sovereign was holding a levee, and went to pay its respects to her.

The only objection I have to bees is the stinging. They and I have frequently disagreed about that, and sometimes I got the best of the argument, though more frequently *they* came off victorious. If they were of a less aggressive and inquisitive turn of mind it would be more pleasant; but they are "mixed mercies," so we need not grumble. At first I thought I should never handle the little creatures, but one becomes accustomed to bad usage, so now I accept the stings as meekly as possible. The worst sting I ever got was when hunting for a queen. While peering into the hive the tip of my nose was suddenly attacked. Now, that is a decidedly vulnerable point, and the tears coursed down my cheeks so heavily that I had to retire, for I could not see. They say that stings cure rheumatism. I do not know whether that is true or not; but this I can aver: For some years I suf-

fered very much from rheumatism; and since we began keeping bees all my rheumatic pains have vanished except in one finger. Did the stings have any thing to do with this?

We read every bee item we see, and I am learning right along. My husband knows far more about bees than I do; but, of course, a man can not get on without his wife. For instance, one day he rushed into the kitchen, wildly pawing the air, and performing a sort of war-dance, very much unlike his usual quiet behavior, and all because a little bee stung him on the nose! He implored me to help him off with his veil, and an unholy joy filled my heart at the scene, for I remembered how he scoffed when I fled with a sting in *my* nose. It all depends on whose nose the bees attack; and it's quite a different matter when it's your own. But we do not trouble much about stings after all—just grin and bear them.

I am not exactly a beekeeper as yet. I am only a beekeeper's assistant. But there is no reason why I too should not go on and do as well as others.

O'Connell, Ontario, Canada, Sept. 30.

THE SHAKEN-PLAN SWARM FOR WOMEN

BY MRS. GERTRUDE GILL

Women are becoming competitors of men in many branches of industry, and successfully too. Then why not in beekeeping? A woman's work is bound to be more or less monotonous (I am speaking now of house-keeping), made up as it is of little tasks that, for the comfort of the family, must be repeated every day. That, together with the indoor atmosphere, often brings more or less nervous strain on the wife and mother. To most of us I believe there is a bond of kinship with Mother Nature; and a little while each day in God's beautiful out-of-doors means new life to tired nerves; and what better or more profitable way to bring this about than to make a study of bees?

The fear of stings keeps many women away from the apiary; but in most cases this fear can be overcome with an increasing knowledge of the natural instincts of these little workers.

Eighteen years ago I came with my husband to Colorado, that Mecca of sunshine and pure air suggested by many physicians for stubborn cases that refuse to yield to pills and powders. In order to be out of doors I began helping him in the apiary; and with his patient teaching and the fascination there is in working with the little busy bee my natural timidity was soon overcome; and with returning health there seem-

ed to open to me a new vista in life I had never before thought of.

If I were to advise younger women just entering the work I should suggest that, to start right, is perhaps the first essential to success in beekeeping, for I believe the time is past for any one with any old method to succeed in apiculture. There are more difficulties to contend with—hard winters, poor seasons, overstocking, and disease; and one must make a study of his own situation, giving his bees careful attention.

I believe in beekeeping for women; but I don't take to the "dishpan and sheet" theory. I should like to tell how we manage this trying part of beekeeping—the swarming season—for I don't take kindly to climbing trees, jumping over ditches, getting through wire fences, and the many athletic feats necessary to catch a swarm that may, after all, object to being caught. Now for this method that, I presume, has grown threadbare to our male readers, but may still be new to the women folks.

First, we will take it for granted that the hive has movable combs, and the condition such that bees would cast a swarm anyhow. Using a little smoke at the entrance, gently remove the cover so as not to disturb the bees more than necessary. Take out the follower; or if there is none, the outside comb; gently loosen the frames with a hive tool, giving plenty of space to lift the combs without crushing the bees. During the swarming season it would be well to begin with the side combs, looking over each one carefully. After locating the queen, set this comb, with the queen and bees on it, at one side, in the shade if the weather is very hot. If you have no helper, lift the hive back from the stand, placing the new hive (which should be prepared beforehand with foundation starters, or sheets, if preferred) on the stand where the old one has just been removed. Level it carefully, thus producing straight combs. Then take the comb having the queen, which should contain eggs or larvæ. Make room in the new hive by removing one frame with starter. Hang this comb with the queen in the center of the new hive, first making sure that all queen-cells have been cut out. Shake the bees from the four center combs of the old colony (not too close, as you will need the young bees to protect the brood left. After putting the frame with foundation at one side of the brood carry the old hive away to the new location. The shaken colony on the old stand will catch the working force.

Hang up the dishpan and sheet. You will not need them. The bees have swarmed just as well as if they did so naturally, and

you are in a better temper than with the old way of letting the bees have their own way, and the whole apiary has not been disturbed with that feverish unrest that is sometimes the case where swarms are in the air all day.

Hyrum, Utah.

[The writer of the above would be better known to our readers, perhaps, if she had signed herself, "Mrs. M. A. Gill." Her practical suggestions show that she is no longer an amateur.—Ed.]

KEEPING BEES FOR PROFIT

BY RUTH C. GIFFORD

I took up beekeeping because I could make some money, and at the same time be at home. My bees averaged about 100 sections per colony last year. The best colony made 146 sections; and the poorest, my only pure Italian colony, 57.

Most of my honey is sold locally—that is, to consumers within a radius of two miles, and by the case to country and town stores for ten miles around. The remainder is sold to a dairy-product store in a city near by. The price is 20 cents a section for fancy and No. 1. I have very little of any other kind, for honey is just as easy to take off at the proper time as it is after it is travel-stained.

I have no wheelbarrow for carrying hives and supers; but I did have a stout express wagon left over from "kid days." I took the sides off and nailed two half-inch cleats lengthwise on the edges of the bottom. These parallel strips are always in position; and, being half an inch higher than the bottom, they prevent bees from being mashed. Lately, though, when interchanging supers I take them off and set them on their sides across the wagon. In this way, after the supers are set off the hive they are parallel to each other, and two or three inches apart. Then they can be replaced in any order desired, and without extra lifting. If a super is full of foundation on which the bees have just started to work I set it on end on the wagon, because the thin combs and foundation would bend under the weight of the bees if the super were placed on its side, and the result would be a lot of sections stuck to the division-boards.

I use the eight-frame hive. If I want to move one when it is full of honey I take out three or four frames, carry the hive and remaining combs to the desired place, then get the frames which were set out, and replace them in the hive. If the distance is longer I take out part of the frames set the hive on the wagon, and set them in it

again. When the new location is reached, I again take out part of the frames, set the hive on the stand, and then replace the frames.

North East, Ind.

AN ARMOR FOR THE TIMID SISTERS

BY MRS. E. R. WILSON

I am very fond of honey or I never would have been interested in bees. But when we started with one colony, and I experienced the first stings, my ardor cooled somewhat, for those stings really did poison me. After one summer, however, I began to contract the bee fever, and have had it ever since. I now work with the bees at all times.

The feminine beekeeper should never trust even the most gentle colony, but should always dress so that being stung severely will be an impossibility. The following is a very safe suit for the use of women in the apiary: Long bicycle boots, reaching to the knee, or buttoned leggings; a pair of long bloomers to fasten below the knee with an inch-wide elastic band, and a band of elastic to hold them in place at the waist; a waist to slip on over the head, made long at the bottom, so as to pass under the elastic band of the bloomers; and a bee-veil sewed to the neck of the waist, and finished with a narrow elastic at the top in order to snap around the hat-crown. A short lightweight skirt and long elbow bee-gloves complete the equipment. A bee must be very smart to do much harm to one in such armor.

When one feels safe the interest is double what it is when fear is the main thought.

I assist my husband in caring for the bees by using the smoker, and he says that I make an excellent helper. When he is away I take all the care of the apiary. The work is hard at times, but not harder than some parts of housework. There certainly is more pleasure and variety in it, for the bees surely keep one guessing.

I would advise women who are beginners to keep only one colony at first, for "chunk" or extracted honey the first season. Section honey is good, and is more suggestive of a woman's work, but is really harder to handle, and it is more difficult to secure results. The bees swarm worse, and this should be avoided by any beginner.

Plenty of room should always be given. Shallow supers are best for a woman to handle, and are pretty enough, when well filled, to please any one.

Last, but not least, clip the queen's wings. Men may not need to; but women certainly do, especially if slightly timid.

Tony, Wis.

Mrs. E. L. Swope demonstrating bees at the Puyallup Fair, Washington.

APICULTURE AS AN OCCUPATION FOR WOMEN

BY MRS. E. L. SWOPE

The reasons for keeping bees are many and various, and the business appeals to man, woman, youth, and child. Bees have been a part of the conscious life of man from the beginning. Not only have they sweetened his daily bread with beneficent honey, but they have also set him an example far more uplifting than any other insect or animal creation.

Beekeeping is the one line of work that the busy woman or the woman of leisure can take up as a remunerative occupation. All beginners should be provided with a silk bee-veil and rubber gloves, because bees do not often attack rubber. They should also visit the bees often and keep up the acquaintance, but should not approach the front of the hive. Always approach a hive from the side or back. When thus protected by veil and gloves any one can handle bees without being stung. However, most people become immune to the poison after

being stung a few times. When bee management has been properly learned bees are as easily handled as birds. Women can care for bees because there is little attention necessary unless one wishes to feed for early brood-rearing, or there is foul brood in the vicinity.

When the swarming season is at hand, and one is provided with a new sectional hive with frames properly fitted with brood-foundation starters, and an Alley queen and drone trap, the bees may be allowed to cluster in the trap or they may be left free to cluster elsewhere. If they cluster on a bush, cut the branch and lay it before the hive, preferably on a large sheet of cheap muslin. Then tap lightly with a stick, and you will soon experience a thrill of enthusiasm. The bees will march into the hive in regular order.

Women who keep bees are of great benefit to their homes and communities. The honey supplied is the most healthful and purest sweet the world knows, and is useful in a variety of ways. It may be used in its natural state on the table, in fruit-canning,

FIG. 1.—Dr. Edna P. Matthews' plan of locating colonies on long concrete foundations.

cooking, baking, and candy-making—in fact, in any thing that sugar and water are used in. It has greater sweetening power than most of the manufactured syrups, and, besides, possesses great medicinal value.

As a remunerative occupation for women it has been my experience that it is extremely profitable, clean, and healthful. When bees have been properly cared for during the winter and spring, and a proper method employed during the summer, a single swarm can produce from 50 to 200 one-pound sections of surplus honey which can always be sold at good prices. It is a business that can be carried on with one or two hives or one or two hundred. It can be carried on at home, thus affording a great opportunity for self-improvement. There should be at least one or two hives of bees in every garden, especially in the rural sections of our country, as the bee is the best

pollenizer, and perfect pollenization means perfect fruit and grain.

Buckley, Wash.

HOW A WOMAN FOUND RECREATION WITH BEES, FRUIT, AND FLOWERS

BY DR. EDNA P. MATTHEWS.

A woman is mentally and physically perfected for bee culture. Twenty-five years of intimate study of women, both in health and

in sickness, gives me the foundation for the above arbitrary statement. Her long years of training in household detail, her quick perception, enthusiasm, and versatility, all combine to make her an ideal bee-keeper. Often longing for the real things of life and their doing, it is a blessing to her if she can pick up an avocation that is pleasing, healthful, and remunerative, thus segregating herself from idleness and frivolity.

"Cottage Garden" is a two-acre fruit and flower farm developed out of a forsaken, barren, suburban knoll composed mostly of subsoil. We took up a proposition of this kind because of a breakdown under a tremendous strain. (Note the willingness of one doctor to take his own medicine!) Our plan, originally, was to put out choice fruits and vegetables for the use of our family, selling the surplus. We wanted a

large planting of fine peonies, a large vineyard of fancy table grapes, and we also wanted bulbs and shrubbery blooming for Memorial day. Our income was standardized at \$500 a year, and the labor at five hours a day; but we found that these could not be kept uniform, as some crops failed on account of conditions beyond our control, and some required twenty-four hours' labor a day. For instance we cut and mar-

FIG. 3.—Winter cases made of barn-siding, which are used in the summer for chicken-coops.

keted 600 dozen peony blossoms and a wagonload of other blossoms in seventy-two hours before Decoration day. Bees were added to pad up this income by providing an alternate. We found the honey crop fluctuated too, as we have only one main pasture in this location, that being white

clover. However, when all crops are good our beloved recreation becomes a very strenuous occupation.

The apiary consists of from twenty-five to fifty stands. We like about thirty. It is essentially a home apiary, and is conducted as such—always in harmony with its sur-

FIG. 4.—Interior of a model shop, showing method of cleaning fixtures.

roundings. The colonies are located about the place in groups convenient for operation and for observation in passing to and fro. One long line extends toward the barn and poultry-yard where duty takes us many times each forenoon. Most of the colonies are located on cement walks, built for the purpose, thirty inches wide, with a slope of one inch toward the south, and shaded by lattice work and grapevines. These cement foundations are spider, toad, and mouse proof, and easily cleaned, and they add to the durability of the hives.

The colonies are usually wintered right on these walks by being moved together in pairs, and packed with cushions of lawn clippings in the supers, which are supported away from the top-bars by pieces of the angle strips taken from the corners of hives as they come from the factory. Over the covers of the hive are first placed pads of wool carpet, and then the felt roofing paper. We also use some winter cases as in Fig. 3, made from barn siding. These have drop fronts and adjustable floors, and are used for chicken-coops in the summer.

The shop was built to conform to the other buildings on the place, and is suitable

The basket shown is a regular market basket with part of a barrel-hoop nailed on for a handle. A short cord with a hook on one end is tied on as shown. I have used such a basket for years to shake swarms into. The basket is hung to a limb; and when the bees cluster they can be carried anywhere you wish.
—A. P. LAWRENCE, Delton, Mich.

for the work to be done in it. The lattice work in front of the porch is cut out enough to allow loaded supers as well as fixtured ones to be stacked up when they are being moved out and in. The room is lighted by electricity, and is fitted with every device for facilitating the work. The cleaning operations extend to every article connected with the bees. All of this work must be done early in the winter, as the pruning, spraying, carpentering work, cement work, etc., must be done later. We first empty all the hives and supers that have to be cleaned; and after repairing and painting them we stack them along the wall ready for the inside fixtures. We use an original device for cleaning fences and holders. The plan is to tack two sheets of No. 3 sandpaper on the edge of the fence, and then with half a sheet to cover a 2 x 4 x 12-inch block which is held in place on the bench by cleats, as shown in Fig. 4. Every part of the fences and holders, such as sides, uprights, etc., may be brought rapidly over the sandpaper and made as good as new or better. All parts needing repairing are laid on a pile and attended to later.

Our tools for repairing are very simple—a couple of plated table-knives cut off square, a tack-puller made from an old file, a pair of small pliers, trays of nails, and a fine saw.

As soon as our twelve-foot bench is full of clean fixtures they are packed away in the supers awaiting the sections later on. We do all this work with the shop unheated, the temperature being about 32 degrees F.

When we get ready to clean the frames, if they are very much soiled we put them in a kettle of Lewis lye, using two pounds to eight gallons of hot water. After a few minutes in the lye we fork them into a tub of water in which four pounds of salt has been dissolved.

For fastening foundation in sections we use a Lewis foundation-fastener, and throw the completed sections on a table having a fence around the top to hold them. For this work and for all bench work, as well as for work with the bees, a pair of spectacles with a 24-inch focus are essential for the use of middle-aged persons.

CLOTHING FOR THE APIARY.

The bee-woman, on approach of spring, will get her clothing ready for work. A short skirt should be worn, clearing the shoe-tops, and wide enough to give free motion. This should be made of brown denim. The shirt-waist should have three buttons at the waist-line on the back to hold the skirt securely. Brown hose, ribbed for neatness, are best. (Boys' hose are more

Mrs. S. E. Howard, Wakefield, Mass., showing that full supers are not too heavy for a woman to lift.

serviceable.) The shoes should be low-heeled and comfortable. A close-fitting jacket made from denim with an easy standing collar, hooked at the throat, a soft hat, and some bee-veils from black netting, complete the outfit.

SOFT CANDY FOR SPRING FEEDING.

In the spring, if feeding seems advisable we give fondant made by the same formula used for our children in the early years. This is made of a pound of granulated sugar, four ounces of water, a pinch of cream of tartar, and a pinch of salt. The mixture is put in a covered pan, and boiled without stirring until it just spins a thread from the upheld spoon. It is then poured into a bowl on a firm table, and when it crinkles like hot milk it should be beaten vigorously. After it turns white it is poured into a paper pie-plate. After a few trials a perfectly smooth cream can be produced.

The explanation of the formation of this candy is that the first crystal stamps the mass. The coarse crystals form on the sides of the uncovered pan; and jarring, while cooling, will start coarse crystallization. The cream of tartar converts a small amount of cane sugar into glucose—quite enough to prevent coarse crystals forming. (Commercial glucose should never be used, as the

makers will not go to the trouble and expense to reneutralize all of the acids used in the conversion of the starch.)

Gradually the colonies are prepared for supers. The top-bars are scraped clean, bulged combs are cut down to the proper thickness, old queen-cells removed, bottom-bars cleaned—every thing being put in the best possible condition, while at the same time the colonies are getting used to being handled. We place three pieces of veneer, two inches wide, across the top-bars, preventing the bees from plastering the section-holders fast to them. We allow the bees to store the miscellaneous flow of the early spring in the brood-chamber.

We have very few swarms during a good honey-flow. The ground slopes to the south, and the avenue is planted with catalpa trees; and, having no high trees about, our swarms rarely leave the place. Last year there were eight that swarmed in succession on the same grapevine.

All finished honey is carefully scraped, and packed in cases. The honey that is produced in shallow extracting-frames is cut out and put in buckets, and sold as bulk comb honey, for which there is quite a demand. Our market is local, most of the sales being made by telephone, although

Prying open the old box hive after most of the bees have been drummed up into a box and dumped on the sheet in front of the new hive.

Transferring not impossible for women to undertake. Brushing the few remaining bees from the combs in the old box-hive.

many of the orders stand from year to year, running all the way from ten to fifty sections. We sell direct to the consumer at a good price, rarely taking less than 25 cents a section.

Dayton, Ohio.

A WOMAN'S WORK

BY MRS. S. E. HOWARD

[To the writer of this article has been accorded the title of "Bee Expert," as she is an authority on bee management from queen-rearing to honey-production. She is a member of the Massachusetts Society of Beekeepers, and also of the National Beekeepers' Association, and is an active worker, writer, and student. Mrs. Howard's success is due in a large measure to the increasing interest in bees in Massachusetts, and her influence has reached distant parts of the country from magazine articles (*McCall's*, *Country Life*, *Suburban Life*, *Country Gentleman*) recounting her experiences and methods. Her yards at Hill Crest, Wakefield, Mass., are models of neatness, and received the commendation of the Massachusetts Society of Beekeepers, which society she entertained August 3, 1912.—ED.]

I first became interested in bees through the gift of a colony in an old soap-box, nailed top and bottom, with a one-inch round hole at the bottom as an entrance. This I had removed to my back yard, and watched it (at a distance) for a season, and

hoped for a swarm to put into a new Langstroth hive with full sheets of foundation which I had provided for the "anticipated," which did not happen that season. During that first summer I watched, talked, and questioned, and read my A B C of Beekeeping, and thought I had the theoretical knowledge, but I lacked the courage to do the practical, which was to transfer that colony to a new hive. Fall came, and no provision made for surplus honey, and none was obtained, but the bees went into winter quarters with abundant stores, and were well protected. The winter months were used for more reading, and planning for the "spring moving" of the bees to their new tenement for which they afterward paid ample rent.

Looking forward to the plum and cherry bloom was a pleasant anticipation, as courage and determination had increased. The propitious day arrived: fruit-bloom, balmy air, and bees at work, and happy, with all conditions favorable. With my veil adjusted, smoker lighted, and hammer, chisel, and hiving-box ready, I proceeded as per directions. With the assistance of my husband (some help is needed by a woman) the en-

A typical "bee mistress" of the Cotswold Hills, England. The old picturesque straw skeps are rapidly disappearing, giving place to more practical modern equipment.

trance to the old hive was closed with a piece of wire screen, and then placed bottom side up, a few feet away from the old stand which was now supplied with a new hive with full sheets of foundation. I then gave the bees a few puffs of smoke and a vigorous drumming on the sides of the old box. After a few minutes' intermission to allow bees to fill up with honey, the bottom of the old hive was removed and the swarm-box placed over it, and bees rushed up into it. Taking it off was a revelation, five hundred or more queens appearing, which afterward proved to be drones not yet ready to fly.

The few steps to the old stand took but a moment, and the bees were shaken on to the frames of foundation, and the cover replaced. Back again for another "boxful," and also the queen if not in the first lot. I carried lot No. 2 to new hive and shook on to a sheet spread on the grass in front of the entrance, and watched for the "lady," whom, I then realized, I had not yet seen.

Soon the orderly marching of the bees in one general direction and into the hive convinced me of my success, and the work was complete; I was victor and I felt I could

do any thing with bees so high was my elation.

I have since had many perplexities, and have yet much to learn; indeed, the possibilities and wonders increase as I progress.

The result for that season was 60 lbs. of honey without a swarm from the hive which we named "Original, No. 1." The next year I divided and made nuclei and called them "Original, No. 2 and 3."

In my beginning I had descriptive names for colonies, given by circumstances and peculiarities, or they took the name of the party I obtained bees from, such as Smith, Wilkins, Daniel's hive, etc.

The accidental removal of the tip of a leg in clipping a queen's wing gave me "Clubfoot," which I especially valued, as she was wonderfully prolific, and bees were industrious, and were the show colony of the place.

From this beginning has been evolved Hill Crest apiary with an average of 50 colonies, and also plans for outyards and a queen-mating yard—all this from my back-yard venture. Hill Crest comprises three acres of fine land upon which I have had erected a double bungalow with piazzas

36 by 6. This is considered as a fruit-farm investment and a summer home, and is not charged up to the bees; in fact, I feel that they earn their rent by services rendered in fertilization of flowers, of small fruit and vegetables, shown by the increased crops.

As in farming, an accurate estimate or system of accounting is quite difficult, as present expenditures may not mature for years, as in apple-tree planting. As a fair estimate I place the income from a hive at \$15.00; yet I know that my own income is greater if I reckon the income from all sources, such as lecture work and writing and teaching, all of which the bee work fits and enables me to do.

My honey is in great local demand, and I am able to obtain five cents advance over the market price—thirty cents for comb and 45 cts. for a pint of extracted, all of which is put up and labeled as of finest quality.

My apiary is on a road much traveled by automobiles and on a car line, and I have a constantly increasing trade with autoists. The sale often reaches four or five boxes or jars to a party.

I have demonstrated that honey can be sold from house to house by a personal canvass, but have not had to practice it for the last two seasons.

Much of the yard manipulation I can accomplish alone, except for a little help in the rush season, and at such times I am able to get a school boy or a volunteer pupil who offers for the experience. Lifting can often be overcome by the use of a light box of ¼-inch stock built on Langstroth dimensions, this to receive part of the frames of the hive to be lifted, removed, or manipulated. My wheelbarrow is an invaluable aid to and from the yard, and as a stand in the yard to hold hive, tools, etc.

Little difficulty is experienced in hiving swarms, and I have been fortunate in keeping down swarming to a reasonable degree.

My approximate yard investment including bees, hives, and accessories, is about \$800—this from a \$25 start six years ago. I also carry about \$200 in new goods for sale to pupils and near-by beekeepers, and to draw from for my own use.

I found that work must be anticipated, and the right thing done at the right time; also that bees will exist under the most adverse conditions, but appreciate and respond to any attention to their betterment. I have also learned that one style of hive should be used exclusively, and I have settled down to the ten-frame dovetailed with Hoffmann staple-spaced frames.

I regard beekeeping as the ideal work for women, and it has opened up new fields and

opportunities to me socially and financially, and also a deeper perception of nature's ways.

Wakefield, Mass.

BEEKEEPING ON THE COTSWOLD HILLS

BY A. H. BOWEN

Last season, now happily over, was one of the worst in this district for some years. To the large apiarist the summer was a nightmare, as the weather from the first of June to the end of August was atrocious, and, with the exception of one fine week in July, honey-gathering was almost an impossibility. The sudden and heavy downpours in June drowned most of the foraging bees which should have been collecting honey during the few hot days which followed, so that the colonies which stored surplus were few and far between.

After a rather severe winter, bees on the whole came through in good form; and with the help of a little feeding they built up rapidly, the spring being unusually mild and favorable.

Around the "Garden Town," fruit-trees blossomed almost a month earlier than usual; and so forward was the season that, at the beginning of May, strong colonies were working hard in the supers. No rain fell for practically eight weeks, during which time the merry hum of the bees was heard from morn till night, taking every advantage of Nature's prodigality.

As a swarming season, 1912 will be remembered by many, especially by the straw-skep beekeepers, who averaged three to six swarms per hive. The first came out during the last week of April; and from thence until August there was a succession of swarms, the last being about the size of a duck's egg.

Those fortunate ones who made a practice of selling the swarms at \$3.00 each reaped a rich harvest.

Runaway swarms have been another feature of this changeable season. In some cases they rushed out without any warning, and flew straight away into some distant tower or oak tree; in others, they clustered a few minutes, and then decamped. I myself lost four swarms which flew away; but one from an adjoining apiary came and took possession of an empty "decoy" hive, several of which I keep in each apiary, and built up into a good colony.

Foul brood has been unusually rampant this season; and with hives packed with brood it spread in an alarming manner. However, by shaking all the worst colonies,

and treating the remainder with a new remedy, I have been able to keep this disease in check. If there is any thing which tends to propagate foul brood it is, in my opinion, a wet and cold summer, when but little honey is being gathered. Under these conditions the bees seem to lose both heart and energy, and the disease spreads like wild-fire through the whole apiary unless preventive measures are taken.

During the latter part of the season robbers were exceedingly troublesome, especially when removing supers: The robbing tendency was indeed so bad that most of the work accomplished had to be carried out in the evening, when flying had ceased for the day. The honey was extracted at night by the aid of a powerful lamp, thus avoiding any excitement in the apiary. At the last extracting I found it a good plan to stack up all the supers of wet combs until the bees had been fed up. They were then placed on the strongest hives to be cleaned out. From the best colony I took 50 lbs. of run honey, but the average yield was only about 10 lbs. per hive, while another apiarist with nearly 200 stocks did not harvest more than half a ton of honey.

Owing to the shortage, honey has been in good demand, though the price is not much higher than last season; and until the public ceases to treat honey as a luxury rather than a necessity the price in a poor year can not be advanced much without injuring the sale. The wholesale price in 1-lb. screw-top bottles ranges from \$1.92 to \$2.16 per dozen, according to quality, and sells retail at 10½ to 24 cts. per jar.

FEEDING SOFT CANDY.

My 80 colonies in ten-frame hives in September were found so destitute of stores that it took 500 lbs. of sugar boiled to syrup to feed them up. The feeders I use are lever-lid cans with about twenty small holes pierced in the lid. Owing to the chilly weather some refused to take down sufficient syrup, and to these were given a large cake of soft and "buttery" candy. This is made by bringing a quart of water to the boil, and adding 12 pounds of refined cane sugar, a teaspoonful of cream of tartar and a little salt. Allow it to simmer for ten minutes, remove it from the fire and stir until it begins to thicken, when it is poured into molds. This candy is beautifully smooth and soft; and as it will keep in this condition for months it is excellent for use in queen-cages.

For a serviceable hive-cover I use a flat telescopic roof with a three-inch rim covered with painted galvanized iron. This, I

consider, makes the finest covering, and it lasts a lifetime.

A COTSWOLD "BEE MISTRESS."

In the accompanying photographs a good idea may be obtained of a typical Cotswold bee-mistress, with her quaint cottage and row of skeps standing in a sheltered corner of the garden. The hand of time has fallen heavily upon the poor old bee-skep, and in a few years hence this picturesque home will have entirely disappeared from our old-world villages.

Cheltenham, England.

A WOMAN WHO HAS BEEN A BEEKEEPER NEARLY FORTY YEARS

BY MRS. ELLA STACKMAN

I am 61 years of age, and for over 39 years I have been engaged more or less in work with the bees or in the workshop, and sometimes with both. I began with four colonies of black bees in the old American hive. I purchased them of a neighbor who was so badly stung by them as to fear to have more experience with them. My husband gave reluctant consent to my having them, with the understanding that I should have the sole care of them, and that he should never be expected to have any thing to do with them; and I well remember how happy I was when they were ranged on a plank behind the house, and I became the proud possessor of them. With what delight I raised the cover which was over a pane of glass at the back of the hives, and looked into their little home, and how fervently I wished that there were some way that I could learn all about them!

A short time afterward I found a stray leaf of GLEANINGS among some waste paper. How eagerly I read and reread it! I sent for GLEANINGS and the A B C book, and began to learn something of the habits of bees. My husband, seeing the magazines and books lying about, soon picked them up and became interested, and, like the male sex in general, assumed with my free consent and approval the leading part in the business. So I shall say that we both began to think that we needed a better hive, and the combs built in frames.

We sent for samples of hives, and finally adopted the Langstroth. We have never regretted our choice, and I still think it the best ever. We chose the Hoffman L. frame and the Miller wide frame for holding eight 4¼ x 4¼ x 1⅞ section boxes.

My better half became more interested in a herd of fine Jerseys twelve years ago, when we left our village home, and moved to the farm. He then turned over what bees

we had at that time (20 colonies) to my sole care, and since then I have been engaged in supplying a few drug firms with bee poison in various forms, and raising honey as a side issue merely, as I have become, during these years, almost immune to the effects of stings.

I have never cut out a hive, but have done about every thing that was ever done with or for a bee. I nailed about all the hive frames and boxes; put foundation in boxes and frames; helped look over our apiary of about 100 to 200 colonies, about once in ten days, during the summer season; assisted in queen-rearing, selling, and shipping full colonies, nuclei, and pounds of bees; uncapped, extracted sometimes when necessary, and every thing else that could be done by a woman.

We exhibited for several years at our State fair, and took the first prize one year for the largest and best exhibit of comb honey ever placed in the building—1400 lbs., all in 1-lb. sections, and good enough to be classed No. 1 or "Fancy."

I sell at my door what honey I raise, and always enjoy very much a good talk with a brother or sister beekeeper. My husband complains sometimes that I enthuse people too much when I talk bees to them, which, perhaps, is true; but my happiest hours have been spent among them.

Auburn, Me., Aug. 22.

DETERMINATION HALF THE BATTLE IN BEE-KEEPING

BY ALICE TRIPP

I came to this country from Wales at an early age, with four older brothers and five sisters in the 70's. I had never eaten honey, nor had I ever seen a hive in my native country. In fact, I was in America several years before I saw a hive. But my brothers cut down countless trees that contained large quantities of honey, sometimes enough to fill a tub. While I liked to eat the honey I was always sorry that the industrious little workers had to be killed in order that we might get the honey.

I was delighted, when learning about the use of hives, to find that the surplus honey could be taken off for family use while the bees stored plenty in the bottom story for their own needs.

I resolved that, if I ever had a home of my own, I would own some hives full of bees.

But, alas! my better half could not be persuaded nor coaxed to let me keep bees. All is well that ends well, however.

One day when my husband was sick in bed I spied a new and strange-looking lump hanging from the limb of a tree across the road. Upon investigation I found it to be a swarm of bees. In a very few minutes I had fixed a box with cross-bars in the center. I mixed up some sugar and water, and wet the cross-bars and part of the inside of the box. I set the box on the ground, and spread out a sheet in front of it. I backed the buggy under the limb, and with a hand-saw cut off the limb and soon climbed out of the buggy with my prize. I placed the treasure gently on the sheet, close to the box. In less than two minutes the bees with the queen in the center were making a bee line for that box.

That was five years ago. I still have my box of bees. They are so docile that I don't try to make them produce much surplus honey, but use them for increase.

I now own 20 hives with movable frames. Although only nine are occupied, I hope to have all full before 1914. I also have three home-made hives containing bees, making 12 colonies at the beginning of 1913. I have had the misfortune to lose one colony nearly every winter.

I once noticed a query as to how a woman manages the heavy lifting. I admit that a ten-frame hive full of honey is all I want to tackle. I first pry the upper story very slowly with two screwdrivers (having nothing better); plant my feet in a good position, take a firm hold and a good breath and determine that I *can* lift it, and I always succeed. There is a good deal in thinking you *can* and *will*.

I extracted over nine gallons of honey from one colony in 1912. That was my best colony. Some came through the winter in poor condition. I don't make the same mistake twice, for I am in the business to stay.

Colo, Iowa.

SUITABLE COSTUME FOR HIVING A SWARM OF BEES

BY MRS. G. W. PERSONS

Last summer I hived a swarm of bees. It was a little after-swarm—about a quart of bees, I think, that came out in July. It hung on the limb of an almond tree all night; and the next morning, as my husband was going to an out-apiary he asked me to hive it about ten o'clock.

I first got a hive and put three frames containing full sheets of foundation and a division-board in it. This I set in a convenient place. By standing on a box and reaching up as high as I could I finally

managed to cut off the limb on which the bees were clustered. This I carried very carefully to the prepared hive; and with one or two quick vigorous shakes I got the bees on the ground at the entrance of the hive. Picking up a pebble I drummed on top of the hive, and soon all the bees were moving in a flock toward the entrance.

I watched them, drumming the while, until I saw the queen go in. I was fully rewarded for my trouble when I saw her, for she was a beautiful yellow virgin. Then, placing a raisin-tray against the hive to protect it from the hot sun, I left it. About five days later the queen was laying, then the hive was moved on a stand with other hives.

Before the season ended they had built themselves up into ten frames, and had filled an extracting-super with alfalfa honey.

When a woman thinks of bees, the utter unfitness of her clothing for the work is the first thing that occurs to her, and justly too, for low shoes and a flapping skirt seem to invite attack. I know whereof I speak. One experience in such clothes is enough. My bee-suit consists of a gymnasium suit with skirt, leggings, veil, and gloves. If I expect to be out in the apiary for only a short time I find that, instead of leggings, an extra pair of stockings with the feet cut off works well.

I bought a pattern and some khaki, and made the suit myself. I made the veil of khaki and wire cloth by taking a piece of the wire cloth 11 by 27 inches, and making a cylinder of it. Over one end and down the back was sewed a piece of khaki. The khaki over the back was for protection from the sun. At the lower edge of the cylinder was sewed a khaki skirt about eleven inches deep. The skirt was tucked inside my collar, and the bees were very effectually kept out. I wear gloves only when the bees are very cross. I find I can work much faster without them, and what do a few stings amount to, any way?

College City, California.

A WOMAN WHO KEEPS BEES BECAUSE SHE LIKES THEM

BY MRS. C. A. SIBLEY

If I had ever seen a honeybee previous to 1900 I did not know what it was. We moved here from Boston that year, and one day some one said that there was a swarm of bees down the road. So we went to see them. There was only one beekeeper in the neighborhood, and we sent him no word,

so the swarm hung there and dwindled just because we didn't know any better. But I talked about the "poor little things" until I was compelled to stop by remarks about "a bee in her bonnet," and "a vacuum under the bonnet."

There was some hay stacked in our meadow; and the next spring our beekeeper friend happening to meet me, he asked if he could buy the hay. When I mentioned his request to my husband he laughed and said, "As you have found a purchaser, complete the bargain and you may have whatever you get." Every one was amused when I exchanged it for a colony of bees. I still think I did not pay enough for those bees, for they have been worth a great deal to me. First, they gave me a new interest at a time when I was very homesick; also they have paid for our magazine and farm papers, for an incubator and brooder, and last fall they helped pay for the corn-harvester. We use an incredible amount of honey on our own table, and I do not know of any thing which so perfectly expresses friendship or sympathy under so many different circumstances as honey does. Our friends appreciate honey more than they do bees.

Of course there is some work that requires strength; but I manage the heavy lifting very easily. I let the men do it. They set the hives in and out of the cellar; but my daughter and I manage the swarms, which usually cluster on an apple tree. We carry out the kitchen table, then we carry out two chairs, a barrel (kept for the purpose), and the brooder-run. We put the table under the tree, the barrel on the table, the brooder-run on the barrel, and the hive on the brooder-run. We use the chairs ourselves, and climb from them to the table. Suppose some day we should put too much weight on the table-leaf and spill the edifice and its builders, and all because the queen's wings are not clipped. However, it is usually "a fine swarm," and is always put into a Danzenbaker hive. Of course, the hives come in the flat, and my son nails them together; and I am afraid he will have to until manufacturers list a hive body that can be put together with a needle and thread. I can't drive large nails very straight. My chickens run in the apiary, and never trouble the bees. Perhaps that is because the hives are set up a foot or more from the ground. Bushel crates make fine hive-stands in a pinch; but there is always a vigorous protest when the "men folks" see them. The hives are just high enough to work over easily. In June we put on the supers with full sheets of foundation. A piece of enamel cloth is placed

between the bees and the cover. One of us peels off the cloth, and the other slides on the super. We seldom use smoke for that; but we need it for removing bee-escapes. I asked Mr. Crane how he liked my smoker. He said he thought that kind was worth about ten cents a bushel. My suspicions are confirmed, and I shall have a new smoker.

Last season the honey-flow was poor in this locality. It was mainly from basswood. I secured a little more than 1000 salable sections from 31 colonies, fall count. There was no surplus from some of them. The local trade takes all my honey, and I could have sold much more. I am "fussy" about scraping, grading, and packing sections. Success in selling depends upon it.

Highgate, Vt.

MISTAKES OF AN AMATEUR

BY MRS. S. L. DORSETT

As I am a beginner in beekeeping, and made several mistakes during the first year, I send you this article, hoping it will help some one to avoid making these same mistakes.

In the spring of 1911 I purchased (from a person going out of the bee business) an outfit consisting of ten eight-frame hives, and two common box hives. There were three colonies of hybrids in eight-frame hives and one colony of leather-colored Italians in another eight-frame hive. There were Italians in one of the box hives also. In the other box hive the bees were so vicious that I never got near enough to them to know what kind they were. The outfit—bees, hives, and all—was delivered on my premises when the snow was about ten inches deep; and, not having a place prepared for them, they were set in a corner of the garden.

BEES FLYING BEFORE HIVES WERE PLACED
ON SUMMER STANDS.

About the 18th of March I had the box hives and the eight-frame hive of Italian bees placed where they were to stand all summer; but the hybrids were not moved until the last week in April. This I now look upon as a mistake, for the bees had been out enough to get their bearings, and kept going back to the place in the garden from which they had been moved, and sometimes the air seemed full of flying bees. I finally set a hive with empty frames at the place in the garden where the colonies had been, and at night there would be a nice cluster inside of the hive. About ten o'clock at night I would bring this hive and set it

over one of the four colonies with a queen-excluder under it, and next day I set another decoy hive in the garden, and at night brought that and the bees to another of the four colonies. I do not know whether I really helped the bees to find their homes or not; but at last there were no more bees flying aimlessly around in the garden. Two of these four colonies cast a swarm, and two stored nearly a superful of surplus honey.

QUEEN-CELLS NOT CUT OUT.

With my outfit there was one eight-frame hive of nice clean empty combs. Wishing to have the Italian bees build up strong I set this hive of empty combs on top of the eight-frame hive containing the colony of Italians in April, and on May 30 they cast a fine large swarm. Now, as I had not learned much about entrance-guards or cutting out queen-cells, I left the bees in the two-story hive, and in two weeks they had cast three after-swarms. I could not think it wise to put these back in the parent hive and kill such splendid young queens; and as I knew nothing about introducing I put each of these small swarms in a separate hive. Of course, by this time the parent hive had very few bees left, so I confined the queen to the bottom hive with a queen-excluder, and let the top story act as super; but they gave very few pounds of surplus after filling their hive nicely for winter.

This mistake proved even more disastrous than moving too late in spring or allowing the after-swarms. I had three after-swarms of splendid Italian bees with small patches of brood about as large as my hand, and scarcely any honey, so I decided to kill the vicious bees in a box hive and one colony of hybrids that had proved cross during the summer, and use these combs and stores for the after-swarms.

CROSS COLONIES AND HYBRIDS DESTROYED BY SULPHUR FUMES.

The last of October I had sand banked up around the two colonies; and, putting some coals in the smoker (another mistake, I presume), I then added a tablespoonful of sulphur for each hive, and drew away just enough sand to allow the mouth of the smoker to enter the entrance. I puffed the sulphur fumes into the hive for a couple of minutes, and drew the sand in place again, and left them until next day. Then the next day I had the old box cut away and then the combs were cut to fit the Hoffman frames. I filled one eight-frame hive with these. I then swept all the dead bees from the combs in the other eight-frame hive. Both hives were now ready, and I put one of the after-swarms into each hive and took

the other bees and swept part in each hive, paying no attention to the queen, supposing there would, of course, be a fight in the hive containing two queens until one was killed. I now had three frames from each of these after-swarms, with small patches of brood and a trifle of honey. I put these and one empty frame into an eight-frame hive and set it on top of a weak colony that had issued as a second swarm from the box hive of Italians. This colony was now put in a shed open to the south. This proved to be no mistake, as the following spring it was a strong colony.

The three colonies which had been united were a total loss. The hives were empty of honey in the spring. All the bees were dead in one hive, and there was little more than a handful in the other. I gave them two frames of brood and two frames of honey; but they were soon all dead, and the two frames of brood were lost also. I suppose they died out because I had taken from them their own larvæ; and the larvæ in the hives I put them in had been killed by the sulphur.

I wonder if there are many who have made so many mistakes in one year.

West Point Pleasant, N. J., Feb. 1.

A WOMAN WHO CAN DO ANY KIND OF WORK ABOUT THE APIARY

BY MRS. C. DISHMAN

There are many women, widows and married, in Texas, who have good locations on their farms and ranches for bees, who would be glad to keep bees if they understood the business; and to such women I would suggest that they get some literature on beekeeping, and a few colonies of bees, and read and practice with a few at first. Many will not have a location for very many colonies; but even a few colonies properly taken care of will furnish honey for family use (and some to spare now and then); and those who have good locations, and money to invest in the business quite extensively might employ an experienced beekeeper for one or two seasons; and by working with him, and reading up on beekeeping, they could soon be making their own spending money, or possibly making much or all of a family's support. Women who are situated so that they can keep a good apiary can give profitable employment to their children as they become large enough to work; and by so doing interest them in work at home. At the same time their help would save the expense of hired help.

I know the first thing a woman thinks of when she considers working with bees is that dreadful sting; but a good veil and gloves will protect her from that annoyance.

I always carry a smoker when I go to work with bees. I can have a swarm, wire frames, put in foundation, assort the combs, and do every thing I have tried to do about the work. I am not sure that I am handy enough with hammer and nails to put frames together as they should be; but my step-daughter can put them together nicely. Other women can do the same if necessary.

I can see no reason why women can not keep bees as successfully as men in many places in this west Texas country. If they will just go into it and stick to it they will be apt to find it pleasant and interesting, and in a few years they will have a very profitable business that will not necessarily interfere with housekeeping or poultry-raising, and such work as is usually carried on on ranches in this country. There is no extra expense in wintering bees in this country. We leave them on the same stands, winter and summer. This is very much in favor of women beekeepers on account of less lifting.

Del Rio, Tex.

How One Woman Extracted Honey Without an Extractor

I was ten years old when my father started my interest in bees. There was a swarm, and after it had settled he told me if I could hive it I might have it; and if I prospered in the bee business I was to call on him for a hive whenever I needed one. Well, I prospered, as we usually do in a work we love. Experience taught me that the bee in many ways is almost akin to man, inasmuch as it wants its own home, and wants to manage it itself. I also learned to work with the bee, and let it have its own way, always when possible and consistent.

I did not have the unique appliances that are now within the reach of beekeepers; and as I read and study about modern conveniences I wonder that, in my rude way, I prospered as well as I did. I never clipped the wings of my queens, nor did I meddle with them in any way; and I never needed to do it. So as far as I could see she was always at her post and capable. I never lost a swarm that I knew of, for I was a most vigilant observer in my apiary.

I had no honey-extractor, but extracted my honey and made my wax at once by setting comb honey in the oven, just hot enough to do the work, taking it out as soon as done, and, when cool, I had both extracted honey and beeswax in one vessel. I took off the wax in a solid cake, and put it into a pan of water, boiled it, and let it cool; then it was ready for use or for sale. The honey I passed through a sieve, and canned it ready for sale or use, fully 12 lbs. of pure honey to the gallon.

I have found in my experience that "eternal vigilance" pays in the bee business fully as well as in any other, and I can not see why the business will not become a success in the hands of any intelligent man or woman.

Heads of Grain from Different Fields

KEEP SWEET

BY IRMA TRUE SOPER

Feelin' sort o' cross and blue?
 Troubles can't be beat?
 Luck the worst you ever knew?
 Time to—jest "keep sweet."
 Toothache? headache? work ain't done?
 Can't keep things as neat
 As you'd like to? 'Tain't much fun;
 But—like bees—"keep sweet."
 Winter time may be too cold
 Jest to suit; but meet
 Old weatherman with smiles so bold—
 Like the bees, "keep sweet."
 May be 'tother way around—
 Don't like summer's heat;
 But you'll see much joy you've found
 If you'll jest "keep sweet."
 If you'll try it, then you'll find
 Troubles *can* be beat;
 Keep on bein' lovin', kind;
 Like the bees—"keep sweet."

Gladwin, Mich.

Comb Honey Sells Easier than Extracted Honey

We have always found that it pays much better to run our apiary for comb honey than for extracted. Comb honey almost sells itself. We never yet have had so much but that we could have easily sold more. One year we had 39,000 lbs. After it was sold, a man wanting a carload wrote us regarding the matter.

If our bees are strong in time for the clover harvest any honey harvest they will work in the sections without any trouble. Thus it is easier for us to make a specialty of comb honey than extracted. Very few persons want extracted honey if they can get comb honey, and they are always willing to pay more for comb honey.

At one time we feel that we have a good market for extracted honey worked up, and then there comes a failure of a honey crop. Our old customers forget how they had liked extracted, and so we have to teach them over and over again; but comb honey sells on sight. I think one reason for this is that it looks so well on the table.

Bulk comb or cut-out honey pays well. If some colonies are too weak to work in supers they can be induced to store cut-out honey by placing old sections at the side of the brood-nest with a slotted division-board at the side of the brood-combs.

CLEANING SUPERS AND HONEY-BOARDS.

For cleaning supers I put on the stove an old wash-boiler filled with water. As soon as it boils I add about a tenth of a can of lye, then put in a super. The propolis soon softens, and washes off easily. Turning it over and over, I rub it by means of a swab having a long handle until it is clean. I then put the super into a tub of water, and let it soak until I have cleaned another. If the propolis does not rub off easily, but just smears over, it is because there is not enough lye in the water. Keep the water near the boiling-point.

HOT-WEATHER SHELTER FOR BEES.

I prefer trees as shelter from the sun because they not only afford shade but allow the air to circulate around the hive, and in the winter, when the leaves have fallen, the warm sunshine on the hive gives the bees a chance to warm up somewhat, and to change their brood-nest if need be.

Roseville, Ill.

MRS. L. C. AXTELL.

How Rapidly Should Increase be Made?

Last September I purchased a beginner's outfit, Buckeye hive, etc. I should like to know how many colonies can be made from this colony, and how to go about it. I fed them sugar syrup, and they seem to be in first-class condition. What supers will fit the Buckeye hive?
 MISS EDITH F. MILLER.

Lake Geneva, Wis., Jan. 14.

[Before we could answer your letter fully we should have to know whether you wish to run these bees you have for increase alone or for some honey together with the increase. Ordinarily we think the latter plan is much the better one. An expert can run for increase alone, and increase one colony to fifteen or twenty under favorable circumstances; but we do not advise a beginner to attempt this. We think it is far better to allow the colony to swarm once, if natural swarming is allowed at all, and then prevent further increase, allowing both the swarm and the parent colony to produce honey. The next year the number of colonies can be doubled again, and so on. The trouble with making a rapid increase in one year is that there is likely to be trouble during the following winter, owing to the fact that many of the colonies will not be strong enough to winter profitably.]

If you intend to increase by artificial methods we would recommend the Alexander plan of making increase, as this plan possesses advantages that most other plans do not.

Any ten-frame super will fit your Buckeye hive, so that it really depends upon what style of supers you prefer.—ED.]

Daughters of Old Queens as Breeders

In May or June, 1910, I purchased a two-frame nucleus, and I now have three colonies of bees. Last year I lost the queen which I bought, but nevertheless my three colonies all have queens which are her daughters. I now want to know whether it will be all right to raise queens from them this year in making increase or would it be better to buy another queen to raise young queens from?

Slingerlands, N. Y.

MISS ALIDA M. PIER.

[If these daughters of the queen that you bought are purely mated, so that their bees are gentle and good workers, there is no reason why you should not breed from them the coming season. If the queens have mated with black drones, their workers will be irritable, of course. We should think one of them, at least, might be suitable to breed from. At any rate, breed from the best of the three. You would not necessarily breed from all the three, any way.—ED.]

Wintering Bees in Box Hives

I want to take up beekeeping. I have two old box hives. One is in a very sadly neglected condition. Some of the comb in it was broken when I received the bees. A good many bees were chilled and are dead, and I know that what are left will have to be fed. What can I do to get them through the winter? I am at a loss to know what to do with them as the weather in this climate is so changeable, and I don't want to lose them. The colony is not large.

I don't know when the queen is with them. How can I tell? Would it be of any use to know how?

Glencoe, Ky., Dec. 31.

MISS A. L. SCROGIN.

[We have our doubts as to whether you will be able to winter the colony you mention. After being moved as they were, and the combs broken down, the chances are that the bees will be dead before spring. As they are in box hives it will be practically impossible for you to tell whether the queen is with

them, or whether they have enough stores. Under the circumstances your best way would be to remove both hives to a well-ventilated dark cellar where the temperature will not go below forty degrees nor above fifty for any length of time. Then, because you are not sure, it would be best to feed warm sugar syrup, two parts of sugar to one of water. If you can get the top off the hive, feed this syrup in shallow dishes right next to the combs, and cover the top up in such a way that the bees can get to the syrup but can not get outside. Place the syrup in the hive late in the afternoon, so that by morning the bees will have quieted down somewhat. We recommend this, owing to the fact that the syrup stimulates the bees and stirs them up considerably, and in the day time they would be likely to fly out and die on the cellar floor. Candy would be safer.—ED.]

Minimum Yield of \$10.00 Per Colony

I have been keeping bees for the past six years with good results. My bees never average me less than \$10.00 a colony, even though we are "away down by the sea." We have great bee feed in the far-famed Bay of Fundy marshes that abound in white clover of the finest quality.

MISS JULIA A. CORBETT.

Amherst Point, Nova Scotia.

Extracting Unripened Honey; Proportion of Water in Honey and Nectar; Where to Store Extracted Honey

Dear Sirs:—Will honey that is extracted when bees are just beginning to seal it ripen in open tanks?

What proportions of honey and water do you take to make it the consistency of nectar?

Do you think it would be all right to store extracted honey after it is in cans, in a dry cement cellar, with plenty of ventilation, and with a cistern in it?

MRS. ALICE BURROWS.

Oran, N. Y., Feb. 2

[With proper facilities for ripening the honey artificially it can undoubtedly be done; but, at the same time, we do not feel like recommending the practice ordinarily. It is better, of course, if you wait until the bees have begun to seal the honey; but we think it is still better, all things considered, if the honey is nearly all sealed before it is extracted.

For the purpose of feeding back, extracted honey is usually thinned down so that the mixture is about 75 per cent of honey and 25 of water. However, such a mixture is not as thin as nectar by any means. Figures regarding the amount of water in nectar vary so much that it is difficult to arrive at definite conclusions. For instance, in the A B C and X Y Z of Bee Culture the percentage of water in four different kinds of nectar varies from 59 to 93 per cent. However, since three of the nectars contain more than 80 per cent of water it may be safe to consider 85 per cent as a safe average of the amount of water in nectar. The average honey may be said to consist of 80 per cent of solids and 20 per cent of water. Now, then, to find the amount of water that must be added to honey to reduce it to the consistency of nectar is a simple problem.

Starting with honey we have a liquid which is approximately 80 per cent solids. We wish to add enough water so that we have a liquid which is only 15 per cent solids, since, as we have explained above, we have selected 85 per cent as being an average amount of water in nectar. Supposing we take ten pounds of honey. Eight pounds of that amount is solids. Now, eight pounds is 80 per cent of ten, and 15 per cent of 53. We must add enough water to our ten pounds of honey, therefore, to bring the weight up to 53. Approximately, therefore, we must add 40 pounds of water—that is, four times the weight of the honey in question.

After honey is in cans, and the cans are sealed, it does not make very much difference where it is stored provided the atmosphere is dry so that the tin will not rust badly. Other things being equal, we should say that the warmer the room where honey of any kind is stored the better.—ED.]

Starting with Three Colonies and Producing 2209 Pounds of Honey the Fourth Year

We secured 2209 lbs. of extracted honey last year from 19 colonies of bees, spring count, in spite of the drouth. We have sold 1900 lbs. at 10 cts., and kept 300 lbs. for our own use.

Our bees seem to be wintering in good order on their summer stands, although we lost a good many during the last cold spell, when the mercury went to six degrees below zero on the 8th of January. We have now 32 colonies, and this is our fourth year, with a start of three stands; that is, we have kept bees for four seasons.

Altus, Okla., Jan. 15.

JAMES G. REID.

Rye Crop as a Substitute for Pollen

I feed my bees rye chop as a substitute for pollen. About the last of February or early in March we have the alder here. It blooms very early, and furnishes an abundance of pollen; but my bees start brood-rearing before the alder blooms, and search everywhere for a bit of chop or meal. It is cool some days; and if I did not feed them chop they would hustle out in search of pollen, become chilled, and die. When the weather begins to get warm, and I notice my bees searching feed-troughs and such places, I have some rye ground fine, and put it in pails or pans, and on warm days set it out in some sunny place. Thousands of bees will soon be working at it in a short time. Feeding rye chop has a direct effect on brood-rearing, as the bees could not do much without pollen or a substitute for it.

About the first of March, if the weather is favorable, I also feed my bees a syrup made of equal parts of granulated sugar and water, to stimulate brood-rearing if the weather is favorable. I think it pays to stimulate brood-rearing in the early spring, so as to have every colony strong in bees, and ready for the honey-flow.

Ethelfelts, Va., Nov. 26.

D. M. BRYANT.

SUMMER'S MUSIC

BY ANNA M. CRAWFORD

Some love the song of the babbling brook,

As it ripples along on its way;

Some love the songs of the merry birds

That sing through the livelong day.

All this is the music of Nature's choir,

That tells of a life so free;

But give me the lull of the sighing wind

And the drone of the honey-bee.

These are the sounds which bring to my heart

The joys of a time to come—

Of buckwheat cakes on a winter's morn,

And sweets that drip from the comb.

And they also bring, with their buzz and hum,

The days of long ago,

When I wandered in childhood's meadow land

Through the fields where wild flowers grow.

Then future and past blend all in one;

And 'tis present joy that gleams

As I drowsily, lazily float away

To a land of beautiful dreams.

And I'm sure all the labor of life I've done

Is naught when compared with these,

For the greatest lesson of life is learned

From the hum of the honey-bees.

Denver, Col.

Our Homes

A. I. ROOT

Blessed are the peacemakers, for they shall be called the children of God.—MATT. 5:9.

Our readers will recall how much I have had to say of late in regard to the need of peace and harmony between Prohibitionists and the Anti-saloon League—see p. 604, GLEANINGS for Sept. 15, and Homes of Nov. 1. Well, just before I left Ohio, Daniel A. Poling, Prohibition candidate for governor of Ohio, gave an address in Medina to a very small audience. It rejoiced my heart to find a man representing the party who had nothing but kind words for the Anti-saloon League, and next morning I had a long friendly talk with him. Well, to be brief, the *American Advance* has just gone into the hands of an "Advance" Publishing Co., and elected our good friend Poling President of said company. The clipping below from the *American Advance* of Feb. 1 explains itself. Once more may God be praised for answering my prayers, and for having raised up a Moses to lead his children "out of the wilderness."

THE HANDCLASP VS. THE HAMMER.

Are the battering-ram and the big stick effective vote winners?

Should they be used indiscriminately in assault upon the enemy and in the recruiting quarters of our civic reform army as well?

There is no livelier question before the friends of prohibition at the present hour; and so well is it handled and answered by our clear-visioned young president, Mr. Daniel A. Poling, that we here give in full his views on the subject as detailed at the national conference Friday afternoon, January 17. We most emphatically agree with their spirit, their logic, and their practical timeliness in this hour when we realize as never before how gracious is our opportunity to increase our forces a hundred fold by earnest, sincere, broad-minded optimistic invitation.

Mr. Poling's remarks were specifically upon the topic, "The Attitude to be Assumed by the Prohibition Party toward Non-partisan Organizations." He said:

I am a party Prohibitionist. I hold no brief to-day for the non-partisan organizations. But uppermost in my mind and heart is the desire and consuming passion that our cause shall triumph. And let it be distinctly understood that I speak to myself as well as to you. It must also be borne in mind as I proceed, that I am not presenting the philosophy of the Prohibition party; that I am not expounding and defending the principles of our organization. My subject and the limit of time demand that I speak only on "Our Attitude toward Non-partisan Organizations." This is the subject assigned me.

1. What has been the attitude of the Prohibition party toward non-partisan organizations? Too frequently it has been that of the Pharisee. We have congratulated ourselves that we were not as other men. With irony and bitterness we have held ourselves aloof, and our political condemnation has been as was the spiritual condemnation of the Pharisee of old—we have not come down from the ballot-box justified!

We have denied to the non-partisan organization its very claim to efficiency. We have scoffed at white maps, declaring that the campaigns they represented

amounted to nothing, and have then demonstrated the fallacy of our position by pointing out the decline of the non-partisan movement when a dry county has gone back into the wet column. If the non-partisan movements had done nothing more than call out from the ranks of silence Hobson and Hanley and Folk and Blair and Stubbs and Littlefield, they would not have lived in vain.

Too frequently we have refused to co-operate in local fights where the issue was drawn squarely between the saloon and the home, between corruption and righteousness, between good government and bad, because we have insisted that the *law* under which the voters were acting was inconsistent and not in harmony with our party principles and the true philosophy of the great reform.

We have made indiscriminate and all-inclusive charges where we have not been able to establish our case in court. We have indulged in personalities—have, in some cases, elevated them to the plane of issues, and our charges have been couched in such generalities that ten times ten thousand men as sincere and brave and honest and unselfish as we can possibly be have had occasion to take personal offense. Our opportunity to reach and marshal them in a conquering political host has been destroyed.

The national speakers and the national press of the liquor organizations vie with each other in searching out and quoting the defamatory utterances of the Prohibition party when they direct their venom against the Anti-saloon League. As for myself, from this day forth I shall guard my tongue and check my pen that the common foe may find no missile of mine to hurl against the onswEEPing hosts of civic righteousness. There is a time for honest differences; there is a place for the frank and rugged discussion of conflicting methods in order that the right plan be found. That time is not in the heat of conflict; that place is not on the firing-line. I speak that which I do know when I say that there are countless men and women in the Anti-saloon League and other non-partisan movements whose souls are as clean and unselfish as the souls of the martyrs whose memories are my political inspiration. I am convinced that in the future we shall make progress only as we eliminate strife from among the temperance forces when they are engaging the enemy. *We must purify our spirit.*

Amos R. Wells, editor of the *Christian Endeavor World*, who voted the Prohibition ticket for the first time this year, received more cantankerous criticisms—ten to one—because he had not "always been with us" than letters of welcome and commendation because of his present "good confession." And he remarks, tritely, "Brethren, those letters go far toward explaining the small size of the Prohibition party."

The Prohibition party will never succeed by bitter and unrestrained criticisms of organizations that differ with it as to method, but stand with it for the destruction of the liquor traffic. The Prohibition party will never succeed by "rough tactics," by vitriolic denunciations, in winning the temperance men of the nation who are not giving it their approval and support.

We shall make progress faster and bring nearer more rapidly the victory's dawning by using our full strength in showing the wisdom and power of our way rather than by "showing up" the real or fancied weaknesses of the other ways. It is possible to insult the intelligence of men by trying to tell them too much. Nine times out of ten, indirect suggestion is more effective than direct. And when we are sorely tempted, when we are refused by those who should be our voting friends, let us remember that "charity suffereth long and is kind." *Out of*

these very furnaces of expediency and denial will come the tempered metal of the final test.

WHAT OF THE FUTURE?

Our attitude must be the attitude of a big man with a big task—a task that he is conscious of not having completed. Such a man is glad for suggestions, is willing to consider new plans, is ready to exchange outgrown policies for more effective methods. He will sacrifice every thing—his pet schemes, his personal desires, his long-established judgments—every thing save *principle*, for the consummation of the truth. I have never been more firmly established in the faith that the liquor institution will not be destroyed until we elect to power a political party committed to its destruction. Upon this rock I stand, but I will not impute spurious motives to the man who is not with me agreed. *Win him* I will if I can.

Our attitude must be the attitude of a sincere organization that has made mistakes—for we have made grave mistakes, and we should not be inclined to throw stones.

Our attitude must be the attitude of an organization conscious that it is responsible for electing, as well as for electrocuting; for winning, as well as for skinning! The intelligent, patriotic voters of the United States of America, the men and women who are thinking temperance to-day, will not be driven or coerced. They must be won.

Our attitude must be the attitude of an organization so conscious of its place and motive that it seeks opportunities to co-operate with all other temperance and no-liquor organizations in programs of common agreement. By so doing, far from losing our identity, we emphasize it. And, men of the Prohibition party, Ohio leads the way. In co-operation with the W. C. T. U., the Christian Endeavorers, the Sunday-schools, and the Anti-saloon League she has adopted as part of her educational propaganda *The Voters' Information Bureau* established by the W. C. T. U., and superintended by Mrs. Lillian Burt of that organization. This bureau, I am convinced, will do more to develop intelligent and permanent anti-liquor sentiment among the masses that will eventually crystallize into votes than any other movement that has arisen in this generation.

Our attitude must be the attitude of an organization too busy to gossip. We do well to remember that the gossip is always despised.

And finally, brethren! The attitude of the Prohibition party must be the attitude of an organization conscious that it has a positive, progressive, constructive program vital to the life of the republic. And in this spirit, with the faith of the fathers, and building better than they knew, let us give to the temperance and Prohibition hosts the slogan of war—*The liquor institution must be destroyed, and there shall be no fratricidal strife.*

High-pressure Gardening

THE HIGH COST OF LIVING, ETC.; SOMETHING ABOUT GOD'S NEW AND PRECIOUS GIFTS.

To-day is January 2, 1913, and so far it has been indeed a happy New Year to me. Let me tell you a few things that have made me happy. On New Year's day a beautiful lot of Buttercup chickens came out of the incubator, and on that same day one of my Indian Runner ducks that *would sit* brought out a brood of ducklings, hatching every egg. I tell you it is wonderfully nice and enjoyable to have a nice little room for a new brood of chicks and another nice room for a brood of ducklings; and then a nice little yard adjoining each one of them. My first brood of Buttercups are now a little over three weeks old; and when I open the door in the morning to let them go out they go out on the wing. The doorstep is a little bit high, so they have learned, in order to save the trouble of climbing over it, just to spread their gauzy wings and sail out like a Wright flying-machine, for all the world. Now another thing that makes them so handsome is their spotted wings, looking for all the world like a brood of partridges. Besides, we have a very pretty garden of sweet potatoes, common potatoes, early peas, lettuce, mustard for the chickens, etc. The thing that has made me happy and set me to thanking God most of all, *just now*, is a new vegetable sent out by the Department of Agriculture. I saw it mentioned in some of the rural Florida papers, and so I sent to Washington and asked them if they

could furnish me some of the tubers. The night before Christmas, when I went to the postoffice I found in my box a card saying, "Package too large to go in the box. Present at the office." This was Christmas eve, remember. When I presented my card, a little bag holding perhaps a couple of quarts of something that looked like potatoes was handed me. I at once decided that it was the new "dasheen," and I also decided that, of all the Christmas presents I have had in seventy years, I do not know that I have ever gotten hold of one that I liked more than this little bag of dasheen. In order to tell you all about it, I am going to quote the printed matter sent me by the Department of Agriculture at Washington:

THE DASHEEN; A NEW ROOT CROP FOR THE SOUTH.

The dasheen is a vegetable from the tropics, related to the ornamental caladium, or elephant-ear, the Hawaiian taro, and to the semi-wild taniar of our southern States. It is much superior to the taniar in quality, and is as easily cooked as the potato. It is one of the great staple food plants of the tropics. Its tubers are similar to the potato in composition, but are drier, and contain from 35 to 75 per cent more protein. The flavor of the cooked tubers is slightly suggestive of boiled chestnuts. Dasheens are baked, boiled, or otherwise cooked, like potatoes.

Dasheens when baked are richer in flavor than baked potatoes. After boiling they may be French fried, mashed, made into croquettes, or used as stuffing for chicken, veal, or other meats.

Although the tubers of the best varieties are not acid, there is always some danger of an acid variety being mixed with them; and for this reason it is better *never to taste the raw tubers*. The burning sensation, caused by this acidity when present, may not be felt for a minute or more after tasting.

Where the frostless season is less than five months, the tubers for planting should be started in sand under glass. Harvesting should be done before frost, and the tubers allowed to dry in the shade for several days before storing.

In storage the tubers must be kept dry, and a free circulation of air allowed among them. They should, therefore, be spread out in rather thin layers. The corms (large central "tubers") are more liable to decay than are the smaller tubers.

The leaves of the dasheen make an excellent substitute for spinach or other greens. On account of their acidity, however, they should *never be tasted raw*. Only the blade of the leaf is used. Of this, remove the thick portion of the midrib, and then boil for not less than 12 to 15 minutes in water to which baking soda at the rate of one teaspoonful to a quart of water has been added. Drain off the soda water, wash with clear boiling water, and then boil for 45 minutes in water seasoned with salt. Other seasoning may be added as desired. Dasheen greens are also cooked by boiling for about 30 minutes with fat meat. Soda is unnecessary with this method. The petioles, or leaf stems, cooked separately from the leaf blades, make a delicious dish. The same methods of cooking may be used, except that, when soda is used, it is better to pour on cold water for the second boiling, and boil for only 15 minutes.

THE DASHEEN AS A CROP, AND ITS INTRODUCTION INTO THE UNITED STATES.

The first experiments made by the Department of Agriculture in the culture of the dasheen, taro, and related root crops, were at the Porto Rico and Hawaii Experiment Stations. A considerable number of varieties from tropical America were collected at the former station, and variety tests were conducted. Following this, in 1905, specimens of the entire collection were brought to Washington and grown in the Department greenhouses. Additions were made to the collection from all parts of the tropics and the Orient, until there has been assembled what is doubtless the largest collection in the world of these useful plants.

From 1906 to 1909 small co-operative experiments in growing these root crops were made in nearly all the southern States, but without very definite results until the latter year, when a one-sixth-acre plot in rich bottom land in Berkeley County, South Carolina, produced 50 bushels of tubers. The most important feature of that year's work was the demonstration that, of all the varieties tested, certain dasheens, which were originally obtained from the Island of Trinidad, British West Indies, were among the best in point of yield, and greatly superior to all others in quality. These Trinidad dasheens, planted 3 to 4 feet apart, produced an average of 7 pounds to the hill, or at the rate of over 400 bushels per acre.

The next season was unfavorable, and satisfactory results were not obtained at the South Carolina plantation; but a preliminary experiment in freshly broken rich "hammock" land at the new Plant Introduction Garden of the Department at Brooksville, Fla., showed that conditions there were favorable for dasheen culture, and in the spring of 1911 a half-acre of heavy-yielding varieties was planted. The half-acre at Brooksville yielded 225 bushels of tubers. About one-third of this was of the Trinidad variety. The soil is a black, very rich sandy loam. Two light applications of fertilizer were made, in the middle and latter parts of the season. Harvesting was done early in November, the crop having had a season of about seven months.

It is no longer a question whether the dasheen will find favor in the United States. It has been served repeatedly on the tables of some of the most fastidious, and has been pronounced a valuable addition to the menu. It was successfully served at the

annual banquet of the National Geographic Society in Washington in January, 1911, and, after a special test, was reported upon favorably by the house committee of an influential New York club.

The Department believes that all southern home gardens having suitable conditions of soil and moisture should contain at least a small area of dasheens, and that a regular market for the surplus over what is needed for home consumption can quickly be created when a steady supply is available.

The little bag which was my Christmas present contained just nineteen tubers; and although these little tubers were very precious, at least to me, I decided that we would have to make a test of one of the smaller ones by having it baked for breakfast. So on Christmas morning we had our first feast of the new potato, or whatever you might call it, served for breakfast. The tuber is remarkably hard and solid. I think they are heavier for the bulk than any potato. When I tell you that the first taste convinced me that it was the most delicious baked potato I ever got hold of in my life, that does not half tell it. Mrs. Root quite agreed with me, although she isn't gifted in becoming over-enthusiastic on new and comparatively untried things. The remaining eighteen tubers were carefully planted, and at this date, Jan. 17, they have all begun to sprout, but none of them are, as yet, above ground. Some of my friends who have read our new potato-book will see what I had to say about my roasted-chestnut potato of years ago. Well, this dasheen resembles that roasted-chestnut potato more than any thing else I have ever gotten hold of. It was so dry and mealy that, when mashed with a fork, the inside rolled out as fine as flour, and looked about as white as flour. I am sure it will prove to be one of the most nourishing and most delicious articles of food that our heavenly Father has ever given to his children.

I have in years past been enthusiastic about a great many new fruits and vegetables, as our older readers may recall. Many of them, it is true, have not quite come up to my expectations. Some of them, although they flourish in the locality where they originated, do not seem to do so well when moved to other places. The Gault raspberry, perhaps, is an illustration of one of this type.

Some of our older readers may remember how enthusiastic I was in regard to the Kumerle lima beans. On getting a 25-cent package of these beans and testing them for quality I became so enamored with the new bean that I finally offered their weight in gold for a few of the precious seeds. The Livingston Seed Company of Columbus, Ohio, finally agreed to part with \$75.00 worth of these Kumerle beans for their

weight in gold. They were impressed similarly to myself. It soon transpired that this bean succeeded in only a few localities, and even then only under extremely favorable seasons. After trying in vain to grow it in sufficient quantities so as to make each reader of GLEANINGS a present of a few of these wonderfully luscious beans, I gave it up; but three or four years afterward, when we had a season that just *suit*ed it, I grew quite a considerable crop. Another thing, it didn't always produce beans of such wonderful excellent quality on all sorts of soils. This is something that we have all had to learn in testing new things.

I was one of the first to demonstrate that celery could be grown on our Medina County soil. Now the crop grown in that region amounts to many thousands of dollars.

The Grand Rapids lettuce, that I discovered and introduced to the world, and gave it its name, has also been the means of furnishing the material for a great industry, for there are now *acres* and *acres* of Grand Rapids* lettuce grown *under glass* in Ohio alone. I do not know how many acres there are in other States devoted to this at the present time.

In a letter that I have recently received from the Department of Agriculture, they promise to furnish me more tubers if I can make use of them. Now, I tell you confidentially what my plan is. As soon as I can get enough of them I want to make a present of a dasheen tuber to every reader of GLEANINGS—that is, to every one who sends the subscription price for one year. It seems to be more exactly suitable for Florida soil and Florida conditions than for any other part of the United States. If I can only make it grow as we are now making sweet potatoes grow, I shall be indeed happy. Before we went home last spring we got some sweet-potato vines over at neighbor Rood's, and just cut them up into short pieces and planted them throughout our garden, where other crops had been gathered off. Well, they had little care during the summer; but when we came back in November we found such a great crop of sweet potatoes that we had all we could use, and enough to give the neighbors, right and left. May God be praised for the sweet potato, and more for the great dasheen which is just now being disseminated throughout our land.

The sorghum or sugar cane that the Department of Agriculture introduced something like forty years ago, produced on rather poor clay soil a quality of cane that made a most delicious syrup. The same sugar cane, when grown on rich bottom land, produced a syrup or sugar that most people would call hardly worth putting on the table. Let us now go back to the dasheen.

At our weekly prayer-meeting I mentioned the dasheen as one of God's new and most precious gifts to men. Our good pastor told me that the excitement was so great around Brooksville, Fla., where the Department of Agriculture has been carrying on test gardens, that it has really been the means of building up the place from what before was an obscure village; and as this new vegetable seems to succeed better so far in Florida than anywhere else, there seems great promise that it shall mean the building up of the whole State of Florida. Just think of it! The most delicious tuber that has ever been given to mankind, yielding at the rate of four or five hundred bushels to the acre!

In speaking of God's gifts, let me repeat a little instance that occurred when I was in California. A real-estate dealer, after asking me a multitude of questions, and finding he could not sell me any real estate, finally said, "Well, stranger, what is your occupation? What do you do for a living, may I be permitted to inquire?" I replied to him that my occupation just then was hunting up God's gifts. He looked at me a little while, thinking perhaps I was half crazy or something of that sort. But he finally asked, "Well, stranger, if you are hunting God's gifts, I take it for granted you don't find many of them up here in this desert."

I replied that I had been delighted from morning to night in finding such an innumerable number of God's greatest and most precious gifts, and I hoped to be able to spend the rest of my days in this wonderfully exciting and happy occupation of searching God's great wide universe for his wonderful gifts to men.

By the way, can any of my readers tell me whether any seed catalog they have gotten hold of mentions the dasheen? Have the seedsmen of our land gotten hold of it? If anybody has had any experience along that line, or grown dasheen or something resembling it, I should be very glad indeed to have the full particulars.

* In an article about "Truck Farming Under Glass," *The Country Gentleman* says: "The Grand Rapids lettuce has revolutionized the culture of this most important greenhouse crop."

Gleanings in Bee Culture

Editorial

IOWA FOUL-BROOD LAW; ATTENTION, IOWA BEEKEEPERS!

THE beekeepers of Iowa are trying to get appropriations for their foul-brood law. It seems they had a law passed, but it carried no appropriation. Every beekeeper in Iowa is requested either to see or write to his Senator or Representative at once, and explain the great need of an appropriation for the foul-brood law already on the statute-books, but which is practically non-operative by reason of no money for carrying on the work of inspection.

SENDING BEES WITHOUT COMBS.

WE must again caution beekeepers against trying to send bees by parcel post. From the amount of correspondence that has been coming in, many people appear to be getting wild about shipping bees without combs. They either do not take GLEANINGS or fail to read our repeated admonitions, and send bees in any kind of box by parcel post. As not all postmasters have read the parcel-post regulations, some of them accept packages of bees in the mails; and if this continues we are liable to have even queen-bees barred. Sending bees in pound packages is a science. We are perfectly willing to tell beekeepers how to do it if they will write us.

A FRUIT-GROWER WHO KNOWS WHAT HE IS TALKING ABOUT.

ONE of our subscribers, Mr. Elias Fox, of Union Center, Wis., has called our attention to the following clipping from *The Fruitman and Gardener*, published at Mt. Vernon, Iowa, taken from their January "Special Spraying" issue:

Never use poison sprays when the fruit trees are in bloom. Just before and just after is the time for spraying.

You injure rather than help your crop by spraying during bloom. Those few days are sacred to the work of pollination.

And the bees, your best friends in that work, must have a clear field. It is adding cruelty to folly to kill your friends at the moment they are doing you a good turn.

Mr. Fox wishes that all journals devoted to fruit-growing in the country would copy

this. We, too, wish that they would, for the item, though short, is right to the point. As it comes from a journal not especially prejudiced in favor of bees, it has all the more weight.

BEE INSPECTION IN CONNECTICUT; A LARGER APPROPRIATION NEEDED.

ACCORDING to that part of the report of the Connecticut Agricultural Experiment Station having to do with bees, we note that the two inspectors, A. W. Yates and H. W. Coley, made an effort during 1912 to inspect those portions of the State not previously covered in this work. European foul brood was found in Litchfield, Norwich, and New London counties.

The appropriation in the States is only \$300, so it is impossible to cover all the ground in one year. At the last convention, however, beekeepers voted to ask for an increased appropriation, and also for certain changes in the law which will make it possible to inspect without complaint, and to place a quarantine upon diseased apiaries. Another change asked for is that a certificate of good health be required to accompany every shipment of bees, whether brought into the State from without or moved from one point to another within the State.

The inspectors barely kept within the appropriation, the total cost of the year's work amounting to \$299.80. The average cost of inspection per colony was 21 cts. Fourteen hundred and thirty-one colonies were inspected in 153 apiaries, and 337 colonies were found diseased with European foul brood in 73 apiaries.

WINDBREAKS AND WINTERING.

WE wish to indorse as heartily as we can the statements made by Mr. Byer, on page 181, of this issue, on the subject of natural windbreaks versus board fences. As we have said before, we believe suitable windbreaks are almost as important factors in wintering as packed double walls. The best-sheltered location—indeed, one that is ideal, in our opinion—is one that is surrounded by low shrubbery or trees—enough so as to

break the force of the wind. When a solid board fence is used, the wind glances upward, is caught by the onward current, bounds downward, hitting one or more rows of hives, with the result that such row will suffer a much greater mortality than the others.

CARELESSNESS IN GRADING.

A SHORT time ago we received a letter from a prominent dealer in New York handling honey, butter, cheese, eggs, etc., complaining in regard to the way in which most producers grade their honey. We give herewith a part of the letter referring to this matter:

There are very few producers of honey in New York State who grade their honey honestly. It is to be regretted, but it remains a fact just the same; and we are unable to make any impression on the graders and producers by any thing that we can write them. Most graders seem to think it is the proper thing to work off a certain percentage in their No. 2 honey in their No. 1 grade, and they do not stop to realize that, by packing their honey in that way, they lose money by doing it.

We doubt whether the producers should be called dishonest, for we think it is more often carelessness or ignorance that accounts for the improper grading. It is, of course, a serious matter; for, from the standpoint of dollars and cents, it means a distinct loss to the producer when his grading is badly done.

THE NEW FOUL-BROOD BILL BEFORE THE LEGISLATURE OF MICHIGAN.

THE beekeepers of Michigan are trying to get a foul-brood law that is more effective than they have had in the past. Every beekeeper in Michigan should immediately write to his Senator and Representative asking for his unqualified support to the bee-disease bill (House bill No. 343) that is now pending before the General Assembly. Explain that bee disease is rapidly spreading all over the United States and Canada, and that it is very necessary that the State of Michigan should have a law that will protect her against the inroads of the disease from other States. Prompt and decisive action on the part of all the beekeepers of the State should be taken at once. The States bordering have much better laws, and it is high time that Michigan should have as good a law as her sister States.

DOUBLING THE STRENGTH OF COLONIES DURING MIDWINTER.

We would call attention to an interesting article by G. T. Whitten, in this issue, on the subject of building up colonies indoors by feeding, and providing a means for flight in a wire-cloth cage. Years ago A. I. Root

succeeded in making colonies in a greenhouse rear brood during cold weather. The bees finally learned to fly out and go back to their hives. While, of course, some were lost, yet brood-rearing continued. Mr. Whitten may have made an improvement in that he uses a small wire-cloth cage into which the bees may fly—so small indeed they may then go back into their hives. Although he does not say so, we take it that at such times they void their feces.

While we do not believe it would be practical for every one to rear brood under the conditions named in Mr. Whitten's article, yet it might be possible for small beekeepers to save a few of their colonies having a mere handful of bees each. The thing is worth trying, for the amount of fuel required would not be large. When there is only one colony, the living-room might be used; but if there are a dozen, a room would have to be prepared with suitable means for ventilation.

We shall be glad to get reports from any of our subscribers who have tried out this plan; and in conclusion we may venture to suggest that not many will be able to succeed as well as Mr. Whitten has done.

THE EFFECT OF SUGAR IN EXCESSIVE AMOUNTS ON THE HUMAN SYSTEM.

IN the January issue of *The Technical World Magazine*, page 516, is an article by Bailey Millard entitled "Our Great Sugar Debauch." We wish every one of our readers might secure a copy for the purpose of reading this article, for it is an astonishing revelation of the enormous quantity of sugar consumed in the United States, and of the bad effect which this excessive use of sugar has on the system. We are prejudiced, of course; but in our opinion the writer should have offered as a solution the substitution of honey for so much sugar. However, even as it stands, the deleterious effect on the health is evident.

The opinions of specialists are quoted, showing that "The bad effects ascribed to sugar as a food are due to its use in larger quantities than three to four ounces a day. . . . The average person eats about three times as much cane sugar as he should." . . . "Many a factory girl and department-store saleswoman makes her entire luncheon from starchy wheat cakes swimming in maple, cane, or corn syrup, and no other dish." The unfortunate girls who work in the candy-factories "are not a healthy-looking lot; and, though plump enough, they are pale of cheek and listless of eye. Sugar inebriates all, with bad stomachs and bad livers."

Referring to the candy sold in shops, the writer says that of 250 samples bought for examination by government chemists "not one was found to be pure, and nearly all had either aniline or coal-tar colors, glucose or terra alba in them, while many had all of these valuable(?) food elements. Even if all candy were pure—that is, if it were composed wholly of sugar, mixed or coated with other edible constituents—it would be unsafe for the average child to gorge himself with it."

Some sound advice is given along the line of allowing children to gratify their natural craving for sugar by eating such foods as dates, figs, prunes, etc.; and we wish that honey had been included; for it is a fact that, perhaps, no scientific man will deny that honey, being an invert sugar—that is, grape sugar—does not have the deleterious effect on the health that cane sugar does, whether made of the sugar cane, sugar beet, or maple sap.

SACBROOD AN OLD BROOD DISEASE UNDER A NEW NAME.

FOR many years back there has been recognized a form of dead brood under the name of pickled brood that is neither European nor American foul brood. It comes and goes at certain seasons, but is never a destructive agent like either one of the old foul-brood diseases. Sometimes it has the appearance of foul brood so far as color is concerned; but it is never rosy like the American type; and while similar to the European type it seldom gets very much headway in a colony. For some years back, Dr. G. F. White, Expert in Bacteriology in the Bureau of Entomology, under Dr. E. F. Phillips, has been studying this peculiar disease; and the result of his investigations as given in Circular No. 169, Bureau of Entomology, show that it is not a fungous disease, as was supposed by Dr. Wm. O. Howard, of Texas, but is due to some other cause. It will be remembered that Dr. Howard attributed the cause to a fungus, to which he gave the name *Aspergillus pollini*. He then suggested the name "pickled brood," which was adopted.

It is mildly contagious, and the infected larvæ turn yellow and then brown. Sometimes the color is gray. The dead specimens may be in unsealed cells, but are generally in the sealed ones. The dead larvæ, says Dr. White, are "almost always extended lengthwise in the cells, and lying with the dorsal side against the lower wall. . . . The form of the larvæ dead of this disease changes much less than it does in

foul brood. The body wall is not easily broken, as a rule, and on this account often the entire larva can be removed from the cell intact." . . . "When removed they have the appearance of a small closed sac. This suggests the name of sacbrood."

The only objection we find to the name is that it may be often confused with black brood, which is still very largely used, especially by those in possession of the older literature on bee diseases. In ordinary discussions in convention the word sacbrood can be very easily confused with black brood; and our own stenographers have repeatedly in our letter-writing confused the terms and substituted the wrong one.* However, this is a matter that will correct itself as time goes on.

CAUSE OF SACBROOD.

So far no microbe or fungus has been discovered as the cause of the disease. Whatever it is, it is so very small that it will pass through a Berkfield filter. Sick and dead larvæ of sacbrood have been macerated and diluted with sterile water. The product was then passed through a Berkfield filter; but it was found that the filtrate would transmit the disease to a healthy colony. Colonies fed with this filtrate would again give the disease to other colonies. It is evident that the disease is contagious. Dr. White concludes "that sacbrood is an infectious disease of the brood of bees caused by an infecting agent that is so small or of such a nature that it will pass through the pores of a Berkfield filter."

This led us to the conclusion that the foul-brood inspectors of the country might be compelled to quarantine an apiary where sacbrood might be found; but in talking with Dr. E. F. Phillips, of the Bureau, afterward, he said he did not think that this would be necessary. The disease at its worst is not very destructive; and when it does make its appearance it affects so few larvæ in a colony that it need cause no great alarm on the part of the beekeeper. While he would advise treating or isolating colonies, he did not believe it would be necessary to quarantine an apiary where it was found.

We are informed that this circular will be followed by a bulletin in which the disease will be treated more fully. Copies of this circular can be obtained by applying to the Superintendent of Documents, Government Printing-office, Washington, D. C., and inclosing five cents per copy. Ask for Circular 169, Bureau of Entomology.

* Indeed, our oldest stenographer got the names wrong in taking down this very editorial. The ear scarcely catches the difference.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

I LIKE that March 1 number. Seems more homelike with so many women-folk around.

THE man with an out-apiary has the special advantage that he can take a colony from one apiary to the other and break it up into several nuclei without any precautionary measures to make the nuclei stay where they are put. [Right you are.—Ed.]

WOMENFOLK do all the work in the hive, while the male members are dead-beats. That would make it seem the appropriate thing that beekeepers should be women; whereas they're nearly all men. Is this another of the cases in which women have been denied their rights all these years?

A CITY daily advises boiling three pounds of sugar syrup with one of honey, and says a great many people like it better than honey "because of the absence of honeycomb, which is dissolved." Now, there's a hint for the United States government, which is having a lot of trouble trying to dissolve certain trusts. Just boil the trusts in three parts sugar and one part honey, and they will be "dissolved."

"UNDER the Colorado rules, the sections must not weigh more than a certain minimum nor more than a certain maximum," p. 140. I suspect you mean *less* than a certain minimum, but where do you get any thing about a maximum? [Yes, certainly, we accept your correction. Where do we get maximum? From the Colorado rules. *Later*. Just looked it up. There is no maximum. The joke is on us.—Ed.]

THE women of several of the large cities took in hand the egg-market, with the result that eggs were bought at 24 cents a dozen by people too poor to pay the previous high prices. Now Chicago women have hammered down the price of apples from 6 cents to 2½ cents a pound. When they get around to it, it would be a glorious thing if they would hammer down the price of honey so that ill-nourished little kids who never taste honey might get an occasional meal of it. "That would lower the price to the beekeeper?" Not a bit of it. It would, if any thing, work the other way by increasing the consumption. The farmers didn't get any less for their eggs and apples because the women butted in. Even if it should bring the beekeeper less, the honeyless kids outnumber the beekeepers.

I'M glad to see that Byer-Root scrap started about feeding honey or sugar syrup, pp. 138 and 141. I hope it will be fought

out to a finish, and that, when the finish comes, we'll know more than we do now. But when you're talking about syrup, are you both talking about syrup of the same strength? and do you mean one part sugar to one part water, or 2½ parts sugar to one part water? That's right—make that Kanuck show the proof for what he "knows." It's none of my funeral, but I'm here to remark in a cautious way that I suspect that a pound of good honey is worth more for bee food than a pound of the best sugar in the world. [Do you mean for brood-rearing or wintering? You do not say. If for the former, we would agree with you; but if for the latter, we should have considerable doubt. In talking about the relative values of food for bees, we must not fail to specify the conditions.—Ed.]

ELIAS FOX, you think the pain is just as great when the sting is promptly removed as when the sting is left in the wound, p. 116. You're right that a sting between the shoulders is something fierce; but might it not be still worse if *not* removed? When the sting is left, does not the poison-sac remain with it, and does not the poison continue to be pumped in for some time? You ask if any one was ever stung by a queen. I never was; but just once in my life I saw a queen sting a worker. [Our experience is that a sting is much more severe if left in the wound than if removed immediately. In the case of a novice or a person who is not accustomed to the effect of the bee-sting poison, the swelling and local fever are, we should say, ten or twenty times more severe. A few years ago, we received what proved to be nearly a "knock-out blow." A bee stung us on the eyelid, under our glasses. The eyes were so suffused with tears that it was impossible to get the sting out. Although there was no swelling, we never received a sting that was more painful. We have been stung many and many a time on the eyelids, without very much discomfort where the sting was removed immediately. As Dr. Miller says, when the whole contents of the poison-sac are allowed to get into the wound, the effect is in proportion to the amount of poison that gets into that wound. The yellowjacket or hornet, if we are correct, does not leave its sting in the wound, and this sting is a mere prick; but the sting from the bee is, in most cases, left in its victim, and so the sting keeps on doing its work, even though the bee itself is smashed.—Ed.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

We are still greatly interested in the cheap shipping of bees without combs, and expect great things are yet to come out of it.

* * *

One of the best things I have ever seen on the subject of feeding back extracted honey in order to secure comb honey is furnished by friend Doolittle on page 44, Jan. 15. It is all there, and all right.

* * *

Those Germans do some original thinking or they would not be supplying their soldiers with tubes of honey while on the march. If it is good for German soldiers it is good for most people engaged in hard or laborious pursuits.

* * *

I read with pleasure of Mr. Chadwick's efforts, at the California State convention of beekeepers, to learn whether alfalfa produces honey of different colors, p. 48. I formerly thought there could be no difference; but after having white-sage honey offered us of a decidedly amber color, and with scarcely a trace of sage flower, and alfalfa that was dark in color and of doubtful flavor, I concluded that "locality" must play a part in the production of honey, of which I had no conception.

* * *

Mr. A. B. Marchant, Jan. 15, p. 45, gives some facts of immense importance to the beekeeping fraternity about the value of pollen in building up weak colonies. We of the North, where pollen is so abundant, have been accustomed to think of honey as a most important item in stimulating bees to rear brood. But it seems that the bringing in of pollen is quite as important. In the North we used to feed rye meal or buckwheat, sometimes in early spring, and we know bees will take it with great eagerness. I wonder if any one has ever tried it in localities where pollen is scarce, and yet the supply of honey is abundant.

* * *

Friend Doolittle, will you please sit up and take notice, for I have somewhat to say to you? In GLEANINGS for Dec. 1, p. 759, you appear to be laboring under so many misapprehensions and misunderstandings that your statements would appear to be very misleading. In a former number of GLEANINGS you took up the subject of finding black queens during a time when robbers are bad. In GLEANINGS for Dec. 1 you say, "After reading this, Mr. Crane wrote,

page 615, Oct. 15, 1911, 'Hello, friend Doolittle! I want to know if you can do that for an hour, when no honey is coming in, without music about your ears in the key of seven sharps.' Yet we have here been finding them this season for many days, sorting out the old or defective ones with great rapidity. We use a queen-sieve, and are not troubled by robbing." You say that the first thing to attract your attention in reading this was that "friend Crane would have the readers of GLEANINGS think that he uses only black and hybrid queens." Beg your pardon, not at all. I would have the readers of GLEANINGS think that, when I have mismated queens or black queens, as we sometimes do after buying in a new yard, we would sort them out as we have time or opportunity, and replace with pure young queens.

Again you say, "The next thing to take my attention was that the editor of one of the departments in GLEANINGS should put off hunting out 'his old and defective' queens until a time of scarcity of nectar had arrived in the fall." Will you please put on your spectacles, my good friend, and read just what I did say? You will see that I said, "We have been finding them *this season* for many days." Nothing was said about the fall. The season of scarcity during 1911 was pretty much all summer. But, again, you say, "But to allow the beginner to believe that a time of scarcity is the best time to supersede old poor failing queens is something hardly admissible in the columns of a paper like GLEANINGS." If you will adjust your glasses once more and read what I said, you will, I think, see that I said absolutely nothing about the best time to supersede old or worthless queens. I referred, as you did, to a time when bees are inclined to rob.

In the fourth paragraph of your department you try to prove that *black* queens can be looked up in a season of scarcity of nectar without danger of stings or robbing if they have been properly handled and managed, by saying that you often work from 10 A. M. to 2 P. M. without robbers or stings at such times, and yet you have already told us that you have no black bees.

In writing as I did I simply desired to call attention to a very simple and effective device that I had found very useful in finding queens when colonies were strong and nectar scarce. In the spring, while colonies are not very strong, it may not be of as much service.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

A rosy hue has begun to make its appearance on the prospects of the season, for just now we are enjoying an old-fashioned "wet spell that makes the heart of the California beekeeper glad. Four and one-half inches for the past 24 hours (Feb. 24) is the report from Los Angeles, though at this place we got but half an inch. The sage seems to be damaged in the interior foothill region much worse than nearer the coast; in fact, Mr. M. H. Mendleson, of Ventura, tells me it is not injured in that vicinity. The prospect for orange bloom is fine at this time, as the buds are starting in almost the usual quantity.

* * *

I am in receipt of a section of comb honey by parcel post from Paul Hunter, of Somerset, Col. The tin section, with its neat covers, makes a handsome and durable holder that stood the trip through the mails, arriving in perfect condition. I am of the opinion, however, that the package is too expensive for common use, and will not displace the wooden ones very fast. Mr. Hunter has demonstrated to my entire satisfaction that these packages will stand the knocks received in the mails, yet the postage on the one section was 16 cts., which would make the delivery by parcel post prohibitive, at least beyond the first zone.

* * *

A meeting of the executive committee of the C. S. B. A. was called at Los Angeles on the 12th of February. Final action was taken on the matter of publishing an association journal. It is to be about the size of the *Beekeepers' Review*, to be issued monthly, and its name will be *The Western Honeybee*. Mr. Geo. L. Emerson, of Los Angeles, is the editor. The committee on marketing, which is composed of the presidents of affiliated clubs, elected Mr. T. O. Andrews, of Corona, chairman, and Mr. C. Hauser, of Sacramento, secretary. The matter of establishing retail markets was left for future action. The purchasing of cans and cases was under consideration, but no definite action was taken, though plans were given out that indicate the association will be able to get cans at a good reduction, and cases in the flat by the carload at a very low figure, making the combined cost a substantial reduction over last year's prices.

* * *

Mr. Editor, I read "Subscriber's" article on p. 59, Jan. 15, and was beginning to get

rather warm until I saw your comment at the end. That soothed me somewhat, but I want to come to the defense of our beekeepers with a few more remarks. "Subscriber" seems to be sore at the entire beekeeping fraternity of this State, and all because of the treatment from one man. He received \$30.00 per month with no experience, which is farm wages, and the green hand is dear at that price in the bee business. The average bee-ranch is not within reach of butcher-shops, and he is lucky to get fresh meat at all. He was *very* lucky in not having to do his own cooking and to clean up his own dirt. The average native would rather sleep out of doors than in, and blankets are considered all that is necessary. I have slept that way many a night, and have enjoyed it. The California beekeeper, on the average, is no worse than any other class of men anywhere else.

* * *

I want to harp a little more on the matter of our exhibit at the Panama Pacific Exposition. As I am secretary of the exhibit committee, much of the work of getting the means together, with which we expect to make the finest exhibit of the kind the world has even seen, will fall on me. I want to say at the beginning that this is not to be in any sense an association affair, but an exhibit of the beekeepers of the State of California. The State Association has taken the matter up to push it through, as it is necessary to have an organization to work through, and to whom those handling the funds are responsible. The plans the exhibit committee have under consideration are of immense proportions and will require much honey, wax, and money. We must have liberal support to be able to complete the plans we have under consideration. Every beekeeper in the State will confer a favor on the exhibit committee if he will notify me at the earliest possible time just what quantity of honey they are willing to donate, let it be any number of cases; or if it is preferable for some to give cash we want to know the amount we can figure on for the work. There are expenses to be met almost immediately in order to get the details worked on time and the work started.

Every beekeeper can also donate some wax, and of this we shall need all we can get. If you are a member of an affiliated club, give your pledge to the secretary of your club. Others who will help, please write direct to me. Get busy, boys. We *must* make a success of this.

Conversations with Doolittle

At Borodino, New York.

MAKING THE BEST OF A SHORT HONEY-FLOW.

"In our locality the honey season is very short, and I wish to know of some plan by which I can get into the supers the most of the honey which comes in during the week or ten days of the honey-flow, without wasting any of it in brood-rearing."

"It will be necessary for you to have plenty of stores for feed during the spring months, so that brood-rearing can go on rapidly, that the combs may be well filled with brood, and the hive well filled with bees when your short flow commences."

"An old beekeeper advised me to make a syrup to feed the bees by mixing sugar and water in equal proportions for feed, so that the combs might be filled with this syrup at the beginning of the harvest, except that part filled with brood. In this way, he said, when nectar comes in from the fields it would have to go into the sections, as there would be no other place for it to be stored."

"Did he think that would be better than to have an abundance of honey stores in the combs?"

"He seemed to think so, for he said it was advisable to feed all the colonies, as those that already had enough food would be stimulated by the feeding, and, as a consequence, would commence raising a lot more brood than they otherwise would. This would mean a host of young bees at the right time; which in turn would mean a big crop of honey from my short bloom. He said that many of the beekeepers of the United States who lived in localities like mine could just as well be getting quite a surplus, and no little money from it, as to be going along on the old plans of securing little or no surplus with nothing but bees for winter. And, often, such a locality would have a downpour of honey, in which case the hives, if filled with capped sugar stores, and just fairly boiling over with bees, would have no room for the big flow except in the supers where it is wanted."

"Well, that sounds well. But did he say any thing about the cost and labor necessary for such a procedure?"

"That was a point I brought up; but he met it with the fact that farmers think nothing of feeding their stock, except to get returns. He claimed that the one who would say he could not afford to feed his cows well because of the cost of the hay and grain that he would feed them would be considered a fool indeed."

"Suppose, however, that you can secure the same result by carrying over combs of

honey from the previous year, what is the object in buying sugar and feeders, and going through with all of this multitudinous labor of feeding every day for six or eight weeks?"

"I hinted at this; but he said that the one who depended upon the bees having enough stores to carry them through to the honey harvest properly, generally found that their *enough* proved so little that the bees would scrimp and economize, so that their stores might be made to last. In this way, he argued, brood-rearing would be cut down; and when the season opened, the hives would have few bees, but little brood, and plenty of empty comb in which to store the first honey which came in from the fields."

"Well, I have to confess that your man, whoever he was, was a good talker; and if it were not true that there are some obstacles in the way of carrying out this plan he would have an argument that it would be hard for any of us to get around. One is the fact that only as you have the most prolific queens will the brood-rearing be kept up at the maximum where every-day feeding is resorted to for weeks in sufficient quantities to stimulate brood-rearing. With nine colonies out of ten, the bees would begin to crowd down the queen by storing too much of the feed, in which case there would be few bees in the hive and very little brood. The sealed honey above and about the brood would be so great that the average strain of bees would not cross over this vast amount of honey to store in the sections even the little which the bees would gather; and the result would be that, instead of a big crop of honey, that coming in from the fields would be still further used to crowd out the brood. When winter arrived, the cluster of bees would be too small to survive, especially if the colony were wintered out of doors."

"Then, too, if everything worked as you were told, and lots of bees were obtained to take advantage of the sections as soon as the flow of nectar commenced, these combs of sugar syrup would soon largely give place to combs filled with brood, as both queen and bees are more largely stimulated with nectar coming from the fields than they are with sugar syrup coming from a feeder. In this way queens which are good enough to keep up the maximum amount of brood under feeding sugar syrup would make a gain as soon as the nectar began to come in from the fields, and the sugar syrup

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

"BULK COMB HONEY" OR "CHUNK HONEY;"
WHICH AND WHY?

Our reason for insisting on the name of "bulk comb honey" for the product as put on the market, here in Texas principally, is to distinguish it from section comb honey on the one hand and old-fashioned "chunk honey" on the other. It can no more be put in the place that chunk honey used to occupy than extracted can be put in the place of the old-fashioned "strained honey."

It is hoped that these various names will soon be understood by the beekeepers of the world. It is of no use to criticise "bulk comb honey" nor the use of the name itself. The two have become so well established, and this kind of honey is produced in Texas to such an extent, that it will be impossible to blot it out. The demand for this kind of honey, for "bulk comb honey," and not "chunk" honey, is so great and so firmly established that this alone will maintain a place in our Texas beekeeping, to be filled by those who will produce it if others will not.

There should not be any objection to the Texans claiming "bulk comb honey" as originating in Texas and being a Texas product. It is too well known that we Texans were the first to resort to the *up-to-date method of producing and putting on the market this kind of honey known as bulk comb honey*; and the mere fact that almost the entire Texas crop is in this form, and especially since the Lone Star State produces no little crop is justification enough to permit it to claim credit for being the home of bulk comb honey. It is simply different from "chunk honey" of long ago.

* * *

WORK FOR MARCH.

It is a splendid idea to have every thing in and about the apiaries, and also in the workshop and honey-house, nice and clean, or "in apple-pie order." This makes a much better appearance in the first place, and helps to make the season's work much more pleasant and agreeable. With the yard cleaned of rubbish, and the trees trimmed to a proper height, the usual obstructions are out of the way, and save a good deal of vexation. A whole lot more work can be done. Especially is this true if every thing is in its place, in the workshop as well as in the other places where the beekeeper has to do his work.

Of great importance is the matter of "spring cleaning" the interior of every

hive of bees. Scraping off the burr-combs, propolis, and fixing up and repairing hives, supers, frames, bottoms, and covers, as well as any broken or misshaped combs, should be done early in the spring. This makes all future manipulation very much easier and more rapid. It seems, also, that the bees of colonies treated in this manner will do better. Since the combs are manipulated as they are being scraped, as we take each one out of the hive, it stirs up the activity of the bees—especially so if much sealed honey is bruised.

It is necessary, of course, that all this work in the hives be done when we have warm weather. It is also necessary to replace the combs as they were taken from the hives, or put them back in such order that the brood-nest will not be disturbed too much.

During the "spring cleaning" we have the best opportunity to remove all unnecessary drone combs and any other combs that are not in first-class condition. It is far better to melt these into wax, and exchange for full sheets of foundation in every frame replaced. It is good practice to "patch up" worker combs after the drone comb is cast out of them, by replacing this with worker comb from other frames. The time required to look after the combs each spring pays well, and should not be overlooked. It is very unprofitable to rear drones in any numbers, and just as much so if we allow crooked or ill-shaped combs in our hives. Every square inch of worker comb put in place of the other will mean just that much more profit to the beekeeper.

All the needed supplies should have been prepared during the winter; and if not already done, foundation should be placed in the first rounds of the supers early enough so that this may not interfere with other work coming on a little later. I do not advocate putting foundation in all supers very far ahead of the time when they will be actually used, since the foundation becomes quite hard, and will not be accepted by the bees quite so readily. I have found that they prefer the fresher foundation.

Continued from page 175.

would be removed to give place to this brood, going into the sections with the nectar from the fields. As a result we should be liable to come in contact with the pure-food law which we beekeepers have been praising since it was enacted."

General Correspondence

RIPENING HONEY ARTIFICIALLY

The Great Majority of Authorities Advise Against the Practice

BY OREL L. HERSHISER

This subject has come in for a good deal of discussion ever since the introduction of the honey-extractor, the latest contribution being that of Mr. I. Hopkins, page 801, Dec. 15, 1912. Advocates of extracting unripe honey practice this for the twofold reason of greater quantity with less labor. The time otherwise spent in uncapping is saved, and the honey is thrown out more quickly and thoroughly because of its thin and watery condition. But the honey thus produced did not and does not meet with favor from the American customer. Some years ago prices of extracted honey became depressed to a point of little or no profit to the producer of the better grades, and there is no doubt that the production of so much unripe honey had more to do with that condition than all else. The writer knows something about it, as he lost a good 2000-pounds-a-year customer by supplying a thousand pounds of fine-looking and apparently ripe basswood honey purchased from another beekeeper, but which, evidently, had been extracted before it was all capped, as it fermented and outgrew the capacity of the pails. What appeared to be the source of profit to the uncapped-honey producers—greater quantity—proved to be the cause of loss, for there could be no profit in quantity when it was more than neutralized by diminution in price. That unripe honey has had and will ever have a depressing effect on the market; and that unprincipled dealers have used and will ever use it as a club to hammer down the price of high-grade honey ripened on the hive can not be successfully denied. For what distributor of honey that has been ripened on the hive, whether apiarist or dealer, has not been adversely affected by unfair competition with unripe honey? If the principle of "greatest profit for the labor" had been strictly adhered to, instead of "greatest quantity for labor," I believe we should all now be getting better prices and profits from our apicultural investments.

Mr. Hopkins observes, "We all know how strongly the ripening of honey anywhere but within the hive has been opposed at different times," and it is within the facts to add that that opposition is growing stronger and sharper from year to year.

Mr. Hopkins cites several prominent authorities in support of his contention in favor of ripening honey outside the hive. Of these, our beloved Quinby died in 1875, and the honey-extractor was not invented until 1868, and probably did not come into even limited use for a year or two later. With that profound reverence that every American beekeeper who is familiar with the fountain heads of his occupation feels for Moses Quinby it does not seem that he could have so attained to that ripeness of experience on this point as to make him a leading authority. It is idle to speculate as to what might have been his ultimate opinion on this point had he lived to mature experience; but it is proper to say that some of the early advocates of the ripening outside the hive later changed their minds.

Mr. L. C. Root has not been extensively engaged in apiculture for about 25 years, but he retains his interest in the subject and in beekeepers. He was present at the convention of the National Beekeepers' Association, Albany, 1910, and entered heartily into the discussion of many subjects. A very able paper from Mr. W. P. Southworth, of Salix Falls, Iowa, on the subject of "Ripening Honey on the Hives," was read at the convention. Mr. Southworth is the manager of an association of beekeepers called "The Western Honey-producers," an association whose annual output reaches 200,000 pounds. He pointed out that ripening honey on the hive is the best method of producing honey that would "taste like more;" that it is not enough that honey be entirely sealed in the comb to be ripe and ready for market, but that it should age on the hive; that the extracting process causes the honey to take in the ferment germs that attack the particles that are not thoroughly inverted or changed from nectar to honey; that he had read the articles written by E. W. Alexander and others on extracting, often during the season, and their methods of artificial ripening, and that he had considered what constituted honey, and would refer to the bulletin published by the Agricultural Department at Washington, D. C., entitled "The Chemical Analysis and Composition of Honey;" that he admired E. W. Alexander, and had studied his writings, and found his methods suitable, with one exception, and that was his method of extracting the nectar from the combs before it was sealed or even well evaporated; that in his location (Iowa), and with the equipment that the average and even extensive beekeeper has, he believes the plan is worse

than a failure; it is a damage to the honey market; that no honey-producer should attempt it unless he wants to enter quite extensively into the manufacture of honey vinegar, and doubts if the nectar would make as good vinegar as ripe honey would; that the all-important question to the consumer is, the flavor of the honey he is eating; and if we want him to eat more honey we must give him the thick delicious honey with the bouquet of the flowers in it; and we can not get this from nectar, nor can man ripen the nectar so that it will be equal to the honey that the bees have finished.

Mr. Southworth's views were sustained in the discussion that followed the reading of the paper, and neither Mr. L. C. Root nor any other member spoke in favor of ripening honey outside the hive.

At the Harrisburg convention of the National Beekeepers' Association, 1907, there was a question by H. Ballou, "Can you get more honey per colony by frequent extracting of the combs during a honey-flow than by tiering up supers with full combs?"

Answered by E. W. Alexander: "Yes, I think we can get nearly twice the amount; but you will require some large tanks for ripening it thoroughly before it is barreled. We make it a point to extract just when the bees commence to cap it. We seldom have any surplus except buckwheat and goldenrod, and occasionally some basswood. We find it a great improvement on the honey from these flowers to keep it in the tanks about two weeks so it will lose a part of the strong odor and unpleasant flavor it has when first extracted. It gives much better satisfaction, and sells far more readily, than if it were barreled up as soon as extracted. I know that any honey that has a strong disagreeable odor and taste is much improved by being exposed to the air a short time."

In the further discussion of this question the writer expressed admiration for nearly all of Mr. Alexander's doctrines; but as to this one of teaching the advisability of extracting honey before it is capped he entered a protest. He pointed out that it might be all right for Mr. Alexander, but that he was answering a question that goes to the beekeeping world; that if we teach beekeepers that honey can be extracted and ripened afterward we shall have about nine-tenths of them not ripening it afterward. The gain in quantity would not be sufficient to compensate for the loss in quality. The writer stated that he himself was interested in producing honey that was as good as the bees could make it.

The president, Mr. Aspinwall, seemed to have a little preference in favor of ripening outside the hive, especially for so skillful a beekeeper as Mr. Alexander, expressing the belief that the gain in quantity was greater than the loss, but said it was right to "warn people against promiscuously doing that sort of thing." Upon inquiry by the President, if there were any artificial processes given in the A B C and X Y Z of Bee Culture, Mr. E. R. Root answered, "These are all out." It may be remarked here that this answer is very significant as showing that it is considered unwise to teach or in any way encourage the ripening of honey outside the hive.

Mr. Selser, a very extensive producer and distributor of honey, and a widely known expert analyst and judge of honeys, having performed extensive and numerous services for the United States government, in that line, said, "I should like to have it go out from this convention before the United States that we do wrong in evaporating honey in tanks instead of letting the bees do it in the ordinary and natural way."

Mr. Holtermann, one of Canada's larger producers and best authorities, expressed admiration for many of Mr. Alexander's writings, but thought him entirely wrong upon this question of taking out honey in the condition in which he speaks of; that *he* can't do it, and manage the way he says he does; for a man who has a stock of bees with the large worker force he speaks of, and has one extracting-super on the hive, can't extract before the honey is capped, and have that honey all in the condition where it is just ready to seal. In a good buckwheat flow we all know that a stock like that can, in one week's time, fill a twelve-frame super. Mr. Holtermann considered Mr. Alexander's mistake in using only one extracting-super. If he would use two or three he would not be able to say that he could get nearly twice the amount of honey by extracting before it is capped.

Finally it was moved by the writer "that it is the sense of this convention that the throwing of unripe honey upon the market, or taking off honey before it is capped—in other words, curing it artificially—is a detriment to the beekeepers of this country." This motion was duly seconded and carried. Of course, it is understood that, at the sudden termination of a honey-flow, there will necessarily be considerable uncapped honey in the supers where an abundance of room is given, and that this will ripen in the natural course, even though not capped; but somehow it seems to lack a little in attaining to that perfect flavor to

be found in honey entirely finished and sealed by the bees.

Also quoting from the paper by Dr. E. F. Phillips, on "The Care of Extraeted Honey," read at the Harrisburg convention, "It is the policy of most beekeepers to allow this ripening to take place in the hive by waiting until the honey is almost all or entirely capped, and this is *undoubtedly the preferable method*. It is a matter of common observation that honey which remains in the hive for a long time has a *better "body,"* and has *more of the characteristic honey aroma*. By ripening in the hive, honey gets its *characteristic flavor to a greater extent than is possible in evaporation outside the hive*. The thorough ripening of honey can not be too strongly recommended. *Honey attracts moisture*, and there is always a tendency for a very thin layer to form on top of the honey in which the water content is very high. In such a film the amount of sugar is low; the acetic-acid-forming bacteria can grow rapidly, and the honey becomes *sour*. In thoroughly ripened honey it is very probable that a film of thinner honey is always present; but in such a case the sugar content is so high that the bacteria *can not grow*" (italics all mine).

Thus it is shown that, for very weighty reasons, many of the foremost beekeepers and distributors of honey in the United States and Canada are unalterably opposed to any method of ripening honey outside the hive; and that, when there was an opportunity to advocate or defend such method, as at the conventions before mentioned, Mr. Alexander was the only open advocate, and he received no support except the slightly favorable remarks by the president, Mr. Aspinwall.

Mr. Hopkins has shown, from the report of Dr. Phillips upon samples of his honey submitted, that it was of superior quality in reference to water content and inversion; but it is noticeable that the doctor is silent on the points of flavor and aroma, which are all-important in making up the value of honey. Take away the element of flavor from honey, and there would be no occupation of apiculture. And if honey ripened outside the hive is so skillfully treated as to make it come well within the legal chemical standard as to water content and inversion, and has a *good flavor*, be assured that, if the same honey had been ripened within the hive by the bees in the natural way, it would have had the *best flavor*.

With his process, requiring special attention to ventilation and the use of artificial heat, the use of the thermometer and

hydrometer, the repeated testings of honey at the top and bottom of the tank, and the mixing, Mr. Hopkins is undoubtedly able to get the best there is out of ripening honey outside the hive; but "how many Hopkins are there?"

The process of securing ripe honey in the natural way is extremely simple. Just leave it on the hive, with the bees, until after the close of the flow, or until perfectly capped; then remove, uncapped, extract, strain into tank, allow time for foreign particles to collect on the surface of the honey, and then draw off the sparkling liquid into suitable containers.

If all honey were allowed to ripen in the hives by the bees, unripe and ruined honey on our markets would be a curiosity; but as long as man assumes this undertaking, wherein, for him, perfection is impossible, there will be many fold more failures than doubtful or partial successes, and the highest attainments in the science of apiculture will not be reached. The beekeeper is wise if he goes not out of his way in resorting to extra care and equipment, to secure honey that necessarily falls short of perfection, and more often proves to be a failure when the best is so easily obtained.

It is no reflection on man to say that the bee knows the most about making honey; for the Creator has endowed her with a superior and inimitable process of ripening it and preserving its flavor, and has withheld this art from man. But in his wisdom he has given us dominion over the bee, and thus it is ours to have perfectly ripened and flavored honey if we will.

Kenmore, N. Y., Jan. 6.

[Our correspondent has done well in gathering together the bibliography against ripening honey artificially. As a matter of fact, we could gather enough more statements, made at different times against the practice, that would fill up one or more journals. The trend of opinion on the part of experts, both producers and honey-buyers, is emphatically against it. In saying this we do not mean to imply that uncapped honey is necessarily unripe. The usual rule is to extract when two-thirds of the cells are capped over. The remaining third of the cells, uncapped, contain honey that is nearly if not quite ripe, and only awaiting the action of the bees to seal it up.

In this connection we may state further that Mr. E. W. Alexander was one of the most valued correspondents we ever had. Perhaps no one writer we ever had has been quoted more than he; and yet, after he had put out the doctrine of extracting before the combs were sealed and ripening in open

tanks, we are frank to say we were condemned by beekeepers and buyers everywhere for letting the doctrine appear in our columns *without a protest*; and Mr. Alexander himself once told us that because of this he had more mad bees (beekeepers) buzzing about his head than he had ever had before.

After saying all this, we believe it is, nevertheless, a fact that in most of the extracting of a whole yard, some combs will be only half sealed and some only a third, yet all are put through the extractor. A few combs out of the whole lot will do no particular harm, even if not ripe.

In favor of Mr. Hopkins, we may say he is one of the best beekeepers in the southern hemisphere. As a man and as a producer he stands high. But his own countrymen, judging from the letters we have received, are opposed to the doctrine of extracting before the combs are sealed, although they may admit that he is probably expert enough to do the work. But we are firm in the belief that any artificially ripened honey, while it may be thoroughly inverted from the standpoint of the chemist, will lack some of the beautiful richness and flavor that is so much prized in honey that has been allowed to ripen on the hives.—Ed.]

QUEENLESS COLONIES GATHER POLLEN BEFORE BECOMING QUEENLESS

BY R. O. MARTIN

On page 797, Dec. 15, Mr. Holtermann says, "The evidence of a queenless-colony condition last fall will be pollen-clogged combs, indicating that the bees gathered pollen, and did not have larvæ to feed the pollen to, and it had, therefore, accumulated in the combs. I find no exception to this. Does this, then, not prove conclusively that queenless colonies do gather pollen?"

The evidence of no larvæ to feed is good; but I do not take much stock in this as an argument to prove that queenless colonies gather pollen. My queenless colonies have not only the pollen, but plenty of honey too, for that matter. Does that prove that queenless bees gather honey and pollen? Certainly not, because *the bees had gathered all or nearly all of this pollen and honey before they lost their queen.*

Did you ever examine a colony that had just lost a queen, and did you not find the combs full of honey and pollen? I am speaking of a colony that has lost a virgin queen on her mating-trip, when nearly every cell of brood had hatched. If the young

queen had made her flight safely, wouldn't the bees have hustled to get that honey and pollen out of her way?

Did you ever see a queen come out of the hive to mate, and watch for her return, she being lost? Have you, then, noted the colony's actions as the bees run out and in, up and down, and almost all over the hive? Have you watched them the next day, and the next, etc.? They are always looking for their queen. They come out on the alighting-board, hesitate a while, fly away in a half-hearted way, and this at a time of the year when the bees are not robbing. Occasionally you will see one with a small amount of pollen; but look at the hive that has a young queen just beginning to lay. See how they run out on the board, and away they go. Do you see any difference in the two colonies? It is easy to distinguish between them, for the bees of one are all hustle and the others seem very lazy. The bees with the queen bring great loads of pollen; but the queenless bees scarcely ever have a load—not enough to clog the combs in a year at that rate.

When the robbers are active it is harder to tell the queenless colony. There is a difference even then, however, for the robbers will hang around the queenless colony more than they will around a colony with a queen. That is the way bees act in this locality.

Naylor, Mo., Jan. 5.

Making Increase Before or After the Main Honey-Flow

Being a subscriber to GLEANINGS I come to you for advice. I had considerable experience with bees in Illinois some 25 years ago; but all conditions here are so entirely different I feel like a beginner. Spring will begin here about Feb. 1; and by the last, bees will be actively at work much of the time. From the middle of March to late in April we get most of our natural swarms with a few any time till late fall—usually a short honey-flow in April from fruit, mostly peaches; then they just about get their living till July 5, when there will be a fair harvest with a steady yield for three months or more. Now, under these conditions please tell me what is the best method to manage so as to secure all the increase possible, and still have all, both old and new, in first-class order for fall harvest.

Winton, Cal., Jan. 23.

L. T. AYRES.

[The conditions here described are ideal for making increase and securing a honey crop, and we believe you can make such increase before the main crop comes on.

As to the method of increase, the one we would recommend to you is given in the A B C and X Y Z of Bee Culture, under the head of "Increase," or what is known as the Alexander plan. We have had very many favorable reports regarding this, and we believe that you will secure better results with less loss of brood than with any other one that you can adopt. For further information you are referred to the subject of "Nuclei," found in its alphabetical order in the same work.—Ed.]

NATURAL SHELTER VS. ARTIFICIAL WIND-BREAKS

BY J. L. BYER

On page 775, Dec. 1, 1912, Mr. Holtermann has an article entitled "Fences for Winter Protection;" and as this is a subject on which I disagree with my friend, naturally the said article was read with more than usual interest. Right here let me say that, while we generally agree on all matters apicultural, yet when such a condition is not possible we can always "agree to disagree" with one another, and that is all there is to it. On this subject of winter protection my experience has been so very much in favor of natural windbreaks, such as hedges, trees, etc., as compared with a bare board fence, that I actually wonder at the claims made for the latter. While the fence may more effectually stop the wind, yet with me the best results have always been obtained from a shelter that breaks the force of the wind and yet allows it to pass gently through the yard. Having just purchased a camera, and being eager for a little practice, I have taken pictures of four of my yards wintering outdoors, and I will briefly explain how the shelter in each yard seems to have worked out in actual practice over a term of seven or eight years.

Fig. 1 shows part of the Markham apiary, which is sheltered on the north, west, and east by apple trees, small fruit, shrubs, etc., with buildings on the north. The house is about 80 feet north of the yard. Here we have always had first-class wintering with the exception of one season when a lot of honey-dew was in the hives. In addition to wintering

well, the bees in this yard always "spring" well too; and the colonies are always boiling over with bees early in fruit bloom.

Fig. 2 shows a small corner of the Cashel apiary. This yard is sheltered on the north by a lot of high evergreens; on the east and west sides by an apple orchard, while the south is protected by buildings. Like the yard already described, the bees here invariably winter in perfect condition, and, with the exception of the year when honey-dew was so plentiful, a colony is rarely missing in the spring. This apiary has 105 colonies, and has had 80 or over for the past six years, with always the same kind of wintering.

Fig. 3 shows a corner of the home yard where, as will be noted, is the board-fence protection advocated by friend Holtermann. Colonies in this yard never winter as well

Mammy and the bees.—*Photograph from M. C. Long, Kansas City, Mo.*

FIG. 2.—Corner of J. L. Byer's "Cashel" apiary.

as in the two just described. The early spring is the time when the fence works havoc, as often on sunny days with a cold wind the bees will fly north and drop by the thousand on the ground (there is often snow there when it is all gone in the yard); and as the sun does not reach them there, they perish in great numbers. This yard is about the only one that I have any spring dwindling in; and the peculiar location is, in my mind, partly responsible for this condition. I have thought of removing the fence altogether; but as I use quilts, a wind-break is a great convenience, as all will testify who have tried to work with the bees in the open, when quilts were over the hives, and a high wind blowing.

Fig. 4 shows the Lovering apiary, 100 miles north of my home; but as this yard was established last summer I can not say how the location will prove in the matter of protection. However, in my opinion the protection afforded is just about perfect. All summer, although the covers were loose on top of the hives, not a single one blew

FIG. 1.—Part of J. L. Byer's "Markham" apiary.

off. North of the yard the rocks gradually rise to quite an elevation, while on all other sides the forest protects the yard. The yard is right out in the forest—in fact, in a nice bit of clearing, making an ideal location, while the trees are not near enough to give too much shade at any time of the year. The only fault we found last summer was that the place was inclined to be too warm, as the hives are on rock, and so much shelter keeps out the breeze too much. In the winter time in this location the thermome-

ter sometimes plays around 40 below zero, so this same shelter is an advantage.

Last fall a venturesome deer strayed among the bees; and, although he came there before the hunting season, from all accounts, I understand he was carried out a corpse, and he wasn't stung to death by bees either. With good boating and fishing near the place, every thing considered, this place is ideal for a summer outing, even if black flies and mosquitoes are quite plentiful in the early part of the season.

I might add that two other yards here in York Co., that are wintering outside, have not been visited since I got the picture-machine; but as the protection is similar to that of the other apiaries, no good would be accomplished by showing them, any way. The 250 colonies wintering in the caves out east, 200 miles from home, are safe from the "camera fiend" for a few months yet; but it is likely they will receive a visit from him some time next May.

Mount Joy, Ontario, Canada.

MAKING INCREASE DURING THE WINTER

Feeding Syrup and Artificial Pollen to Bees that Have a Flying Cage in a Warm Room

BY GEORGE T. WHITTEN

For the past four winters I have been experimenting with bees in a warm room for winter increase, and I find I can easily make two swarms from one colony, making three in the spring. This seems to be the limit, as I have only two windows available for the purpose; but I am perfectly satis-

FIG. 3.—Corner of J. L. Byer's home apiary.

fied that it can be done, to the limit of the number of frames of bees on hand Sept. 1, and of windows available, if there is a room where the heat can be controlled as desired.

This work can be begun at any time during the winter by moving a colony inside and furnishing the necessary temperature of about 70 degrees per flying cage. The bees must be fed sugar syrup, rye flour, and water every day. Thus treated the queen

will begin laying in about three weeks, and keep it up as long as fed. Pollen, or a substitute, such as rye flour, is as necessary to keep the queen laying as syrup and water. Feed should be given every day, and two or three times a day is better. If the feeding is stopped for a few days the queen will stop laying, and it takes four to six days to get her started again. My experience has been that a queen will do just as

FIG. 4.—J. L. Byer's "Lovering" apiary in winter quarters.

Delegates in Attendance at the National Beekeepers

good work the following summer after being worked in winter in this way as though she had been wintered in the ordinary way. I can see no difference.

I feed sugar syrup wholly in winter—no honey—two parts sugar to one of water. I put the sugar in a jar and put the water in warm, not hot, and stir a little, then let it stand for a while to dissolve. By stirring it two or three times there is but little that settles in the bottom hard; then by running it through a cheese-cloth strainer this is taken out, leaving the syrup clear to feed. I have never had any of this crystallize in the hive.

The most satisfactory place for feeding syrup that I have tried is over the cluster. On all hives I have a frame made of pine, $\frac{1}{2}$ by $\frac{3}{4}$ inch, just large enough to cover the hive top, and with wire netting on one side. These are on the hives all the year. In winter they are over the top of the hive, under the super to hold the packing. This gives the bees a space over the frames close up under the packing. In summer they are on top of the super or supers. The cover of the hive may be removed at any time to look into the super without disturbing the bees. They do not come up and bother. I place two or three thicknesses of cheese-

Cincinnati, Feb. 12, 13.—See report on page 190.

cloth over the frame, and spread the syrup evenly over this. The bees can come up under the wire and get the food without leaving the cluster very much. With the super on top they can be fed at any time by removing the cover. There is no danger of robbing when fed in this way, and the heat of the hive keeps the food warm.

The best way to feed rye flour is to sprinkle it on plants, or spread it on something that the bees can hang on while they load up. They do not take it readily from a dish placed on the floor, but will, when they can, hang on to the edge of the feeder, or the under side. I lay a cheese-cloth on

top of the cage, or hang it over the slanting end next to the window. They come up and hang on the under side with one foot, and load on all they can. The food should be placed where the light is strongest, for that is where they gather thickest.

I built a hive specially for observation work, that has been in use for three years. This gives perfect satisfaction. It is built on the half-circle plan, with glass on all sides. The frames are so arranged that they can be turned so that both sides of each frame may be examined at any time. Four turn to the left and four to the right. A rim is provided at the bottom, and handles

Geo. T. Whitten's observation hive in a greenhouse. The combs swing from side to side, so that all their surfaces may be inspected.

project out through, by which the frames are turned as desired.

The flying cage used is two feet square, covered with wire, with an entrance in the back for the hive, and one at the front to allow the bees to go outside in warm weather.

The great advantage of a warm room,

and the principal one, is in keeping an even temperature, or nearly, so they can extend the brood-nest to any size without danger of the brood and eggs being chilled, which is the principal cause of spring dwindling. There are many eggs laid that do not hatch, for the reason that there are not enough bees to cover them when the temperature

drops after a warm spell. I have had this occur in the house when, for any reason, the temperature dropped too low, as by opening the window to cool the room, to drive the bees into the hive from the cage; or when I wish to change the plants or clean it out. That day, Dec. 21, I found young half-grown bees out in the cage.

This cage is close to a radiator, so there are bees flying at all times during the day and in the evening

Another hive, located out of doors, with the cage attached.

Bankston's nursery cage. Each compartment has room for a small piece of comb filled with honey.

as long as there is a light in the same room. To-day, Dec. 24, while the snow is falling fast outside, the bees are flying and humming in their cage as though it were June instead of Christmas.

Hartford, Ct.

A NEW NURSERY CAGE

BY C. B. BANKSTON

About 22 years ago there came into use what was known as the Alley nursery cage. This cage was simply a little square block of wood with one large hole in the middle, and two half-inch holes in one end. One of the small holes was for a sponge to contain honey for the young or old queen to eat. The other was for the insertion of the queen-cell. Twenty of the cages just fit inside of a Langstroth brood-frame.

We used this cage for many years. It beat the old lamp nursery, but it had many faults. The sponge would get dry, so that the queens would starve. A great many would hatch with crippled wings or were otherwise deformed.

I tried different makes of cages, and finally set to work and invented one myself.

I have used it nearly ten years, and have no idea of replacing it with any thing I have ever seen along this line.

In the Oct. 15th issue, page 663, is an illustration of a nursery which, apparently, is the old Alley cage re-invented. The accompanying engraving shows my new cage, which I call the "New Century" because I think it is new. The queens emerge in it perfectly, and they live and develop in it as well as they will among the bees, because they have access to honey, warmth, and all the conditions necessary for their well being. I fill the little combs full of honey, trim the queen-cells, touch the wax plug to the hot smoker, and stick the cell to the plug. I can have 60 queens hatch in one brood-frame.

Buffalo, Texas.

SEPARATING HONEY FROM CAPPINGS BY CENTRIFUGAL FORCE

BY R. F. HOLTERMANN

The discussions which take place at conventions are by no means the only source of information for the beekeepers who attend them. Conversations, sometimes in part in

Capping-basket to fit the comb-pocket in an extractor for use in separating the honey from cappings by centrifugal force.

Colonies in tenement hives.

confidence, have for me been a fruitful source of instruction. There is, however, yet another source of information, and that is to visit some of the beekeepers in their homes after the convention is over. Such kindnesses to me have been frequent, and in no small degree have they been extended to me in New York State.

In December last I went to New York under the New York State Board of Agriculture, and upon completing my engagement I accepted several invitations from beekeepers to visit them at their homes and

apiaries. My first visit was with D. R. Hardy, Burr's Mills, N. Y. It was a stormy night when Geo. B. Howe, president of the New York State Association, and I landed at Watertown; but we were met by Mr. Hardy and taken to his home in the country, and made welcome. After supper a brief visit was paid to the bee-cellar and honey-house. Mr. Hardy is an unusually painstaking beekeeper. He is not afraid to follow original ideas, and he has evidently met with a more than average amount of success. He has been developing a strain

of bees about one quarter Carniolan and three quarters Italian. Turning to me, he said, "I can remember your suggestion years ago at a State convention, that such a bee was, in your estimation, a superior one." Mr. Hardy has been acting upon the correctness of this idea, and he appears to be well satisfied with the result.

For extracting, Mr. Hardy uses a power extractor and a three-horse-power gasoline-engine. Turning to the capping-can he said, "I want to show you

Hives set too close together for easy inspection.

my method of taking the honey from the cappings." A large wooden paddle was shown as the instrument by means of which he broke up the sheets of cappings. When these had been broken into small particles by stirring, he next put them into a pocket consisting of a box the size of a Langstroth frame. The top, bottom, and sides were formed by a wooden wide frame, and fine tinned wire cloth was nailed to each side. In the top piece (as it stands in the extractor) an opening was cut in the wood, through which, by means of a specially made funnel, the broken-up cappings were crowded, after which the device was placed in the extractor, just as a Langstroth frame would be inserted, and the honey was extracted just as honey is extracted from the comb. I saw the wax after the extracting, and found it very free from honey, and I felt that this plan filled a "long-felt want" in my extracting equipment. I told Mr. Hardy that I would make this outfit in the way of a basket with one entire side made to slide on and off. To this Mr. Hardy acquiesced, remarking that the box into which the cappings were placed could be made of heavy tin. I have six such baskets now ready for use. We shall have to call this apiarian implement the Hardy capping-extractor.

Brantford, Canada.

[This new method of draining cappings by centrifugal force is one that gives promise of much merit. We shall try it ourselves the coming season. Mr. Hardy's apiary is shown in the cover engraving for this issue.—ED.]

EXPERIENCES OF A FOUL-BROOD INSPECTOR

The Greatest Trouble that of Opening Hives

BY J. E. CRANE

I fancy that a good set of burglar's tools would be a very good outfit for an inspector in opening even movable-comb hives; for in nothing have I been more disappointed than in opening such hives. I believe that, as yards run, it is as easy to get into box hives as into those containing combs that are supposed to be movable. I thought at first it was because I found so many with Hoffman frames, and I still think the Langstroth more readily movable, when properly constructed; but the greatest difficulty has been because of crooked combs. Many beekeepers appear to be afraid of their bees, then hive them and run. At night they set the new swarm in its place as quickly as possible, and get away without stopping to

see whether every thing is all right. So I find hives with Langstroth frames properly spaced at one end, while at the other they have all slid together with no uncertain result.

HIVES STAND TOO CLOSE TOGETHER.

Some of my vexations have been caused by the position of hives which were set in long rows, perhaps not more than four inches apart, and which it was necessary to lift from their stands before I could open them. The three in the illustration will show what I mean; but three are easy compared to twenty. Often it is easier to open hives and to examine them than to lift off the stone, boards, and slate with which they are covered. I often think, as I make my rounds, how much the majority of beekeepers are losing by not knowing better how to keep bees.

NOT NECESSARY TO DISINFECT HIVE-BODIES.

When I began work, and found foul brood in almost every yard, it seemed like trying to fight an enemy that used noiseless guns and smokeless powder; but after more experience it seems to be controlled by well-defined laws; and those who are willing to follow a few easily learned rules can rid their yards of it. I am watching with a good deal of interest in order to determine whether it is necessary to burn out brood-chambers or to disinfect them otherwise. I have suggested to some experienced beekeepers to try it, without burning or disinfecting, and so far it has seemed to work well. The fact that many beekeepers have overcome the disease by leaving colonies queenless for a time would seem to indicate that it is not always necessary to burn out hives for the purpose of destroying all germs of disease.

If it proves successful it will greatly lessen the work of changing combs, especially where large chaff hives are used.

CLEANING THE TOOLS.

How shall we disinfect the tools we work with? Some inspectors advise boiling in hot water for half an hour—a safe provision against carrying infection to the next yard, no doubt, but far from practical, both because of the difficulty in getting hot water and the loss of time. Then an inspector's fingers often become soiled with foul-broody honey. Must they be cooked with the hive-tools for half an hour? I have compromised; and instead of boiling with water I thrust my hive-tool, when through with one yard, or before commencing on another, into the ground, in and out, until it is bright and clean, and I have no fear of its carrying disease. I also wash my hands in water if I can get it.

DEAD LARVAE ON THE GROUND SPREAD THE DISEASE.

There is one way by which I think it is possible that disease may be spread of which I have not spoken. Where many hives are diseased, thousands of the dead larvæ are hauled out of the entrances and left near by on the ground. These, decaying, may (after a little) become dust to be blown on or into flowers, into the entrances of hives, or carried by the bees where they will get into the food of young larvæ. I have in some instances advised a change of location with entirely satisfactory results. I have found two or three beekeepers who feed their bees a weak brine, thinking it very beneficial.

CEMENT HIVE.

One man I met had constructed a hive of cement. Unfortunately he had made a slight mistake in the size, so he could not use his frames in it, and so had never tried it. It looked substantial, and might prove a success in some parts of the country.

HONEY FROM CORN.

Another beekeeper told me how his bees gathered considerable honey from corn, and, later in the season, wrote me that again they had stored some ten or twelve pounds to the hive, thus helping him to solve his winter problem, for his bees, like most bees in our State, had not stored enough to winter on.

THE PLEASANT PART OF THE WORK.

While there are many unpleasant features in connection with inspection work, there are many pleasant experiences to be thankful for. It is pleasant to study the honey resources of one's State, and to see the advantages and disadvantages of different sections. One has also an opportunity to make some choice acquaintances, and to visit old friends without much loss of time or expense. One such I must mention.

Forty-three years ago I learned of a man about seventy miles away who wanted to sell out his entire stock of bees, as he had met with some loss and was quite disgusted. After some correspondence I went to his place and bought most of his stock. He was a very intelligent beekeeper for those times, and I much enjoyed the time I was with him, as he told me so much that was then new. Afterward we corresponded for a time, and I lost track of him, and I thought he had of me. While looking up foul brood in his neighborhood I thought I would go over to see him and inspect his bees, for I knew he would have some, for who ever, after once falling in love with bees, would go without them? I found him and his good wife more than pleased to see

me, and he could not do enough for me. I found that he had a good stock of Italian bees; and if they defend their homes against foul brood as vigorously as they did against the interference of the inspector it will be a long time before disease will do them any harm. After a most delightful visit he took me in his carriage over to see a neighboring beekeeper, and then to the trolley line.

Middlebury, Vt.—*The End.*

BRIEF REPORT OF THE NATIONAL CONVENTION AT CINCINNATI

BY E. R. ROOT

The attendance at this meeting was not large—indeed it was, perhaps, the smallest of any of its kind that we have ever attended. At no time were there over fifty present. In another way it was a large convention, because it was a representative meeting. There were delegates, each representing an affiliated society, from Vermont, Massachusetts, New Jersey, Pennsylvania, New York, Ohio, Kentucky, Michigan, Indiana, Virginia, Tennessee, Iowa, Oregon, Colorado, Idaho, and Texas; or, all together, a membership of several hundred. Some of the associations sent more than one delegate. In this connection it should be explained that this convention differed from all others in that it was a *delegate* meeting. Besides delegates, there were members of the Association who, while they had the privilege of the floor, had no vote in business matters. Then, as is usually the case, there was some local attendance, but not nearly as much as we ordinarily see at conventions located at Cincinnati. For that matter, there would have been a much larger local attendance, we understand, if the meeting had been held earlier, say along in September or October.

The Bureau of Entomology, Washington, D. C., was represented by Dr. E. F. Phillips, in Charge of Apiculture, and by Geo. F. Demuth. Dr. Burton N. Gates, Dean of the Apicultural School at Amherst, Mass., was also present. Indeed, he was elected presiding officer in the absence of Mr. Geo. W. York, the regular President. Mr. R. F. Holtermann and Mr. Foster, of Canada, represented Canada, but not as delegates.

This convention was unlike any of its predecessors in that its primary object was the transaction of business, and a lot of it was done. The principal subject of discussion at the first session was whether the National Association should have an official organ. Something over a year ago the Board of Directors voted to buy the *Beekeepers' Review* of Secretary Tyrrell. The

question arose whether the Directors had the authority to adopt and publish an organ, and expend a thousand dollars for the good will of a paper. Some took the ground that the Directors had exceeded their authority. Others held that the National organization could not afford at this time to pay out a thousand dollars. These matters were thrashed over in convention, and at one time the discussion became somewhat warm. The matter was finally referred to a committee, with instructions to report at a later session. The committee were out for a considerable length of time, but finally turned in their report, questioning the policy of the Directors, but finding that the latter had not exceeded their authority. At the same time, they made certain recommendations, some of which related to the editorial policies of the *Review*, while others had to do with the question of the purchase of bee supplies for the members of the Association, as well as to the selling of their product—in short, carrying out the general principle of co-operation.

There was considerable discussion as to the price that should be charged for membership. It finally ended with the recommendation, which was adopted, that the fee of \$1.50 should be retained as before. Fifty cents is to be used for branch or affiliated societies, and \$1.00 for *The Beekeepers' Review*. Sec. Tyrrell explained that this money could not be used to cover both the *Review* and membership dues, as that would be contrary to the postal regulations. This leaves, as we understand it, no funds for the National Association except the profits that may accrue from the publication of the official organ. A member may elect not to take the *Review*, and apply his dollar to the National.

There was considerable discussion as to whether the whole membership fee should not have been increased so that a part could be devoted to the branch, a part to the *Review*, and a part to the National itself, apart from the *Review*; but Sec. Tyrrell did not believe it was wise at this time to charge the extra price. The committee, therefore, made its report accordingly.

Other routine matters of business were transacted, such as revising the constitution, passing resolutions of thanks for courtesies extended, etc. While the committee were out preparing their reports, there was a general discussion of several subjects. One of these topics was

THE DECLINE IN THE PRODUCTION OF COMB HONEY AND THE INCREASE IN THAT OF EXTRACTED.

While poor grading and poor packing

were given as a cause for a part of this, several contended that the present market prices were more favorable to extracted. Two or three claimed that there was actually more money in the production of extracted at eight cents than comb honey at sixteen. The discussion finally centered on the subject of the granulation of Western comb honey; for it was contended that this granulation evil was disgusting the dealer so that he was refusing to buy. Mr. Muth, one of the largest honey-buyers, in a half-facetious and half-serious way, said he felt as though he were being swindled when he bought Western comb honey. He complained that he had a large quantity on hand that has granulated, and that was fit to sell only to Dagoes, and he thought it was time that some of these Western producers should produce extracted rather than comb honey. Mr. Weber, another dealer, said he had had a similar experience. Dr. E. F. Phillips, of the Bureau of Entomology, was glad that this matter had come up, for now the Western men present would have a chance to know that there was a general complaint about Western alfalfa honey granulating while in the hands of Eastern dealers. Like Mr. Muth, he believed that some of them, at least, ought to produce extracted rather than comb honey.

Mr. Wesley Foster, of the Colorado Honey-producers' Association, contended that not *all* Western alfalfa honey would granulate. There are certain districts in Colorado where a mixture of alfalfa and other sources would granulate much more readily than the pure alfalfa. He said he hoped the Eastern buyers would understand there is a large amount of Colorado alfalfa honey, and a good deal of it, too, that does not granulate.

Mr. Anderson, of the Idaho Beekeepers' Association, indignantly denied that Idaho honey granulates. *Their* honey, he said, was made up largely of sweet clover and alfalfa; that the combination would remain liquid as long as any comb honey in the world if properly taken care of. With all deference to Mr. Muth their honey was "fit for the gods" and not for the Dagoes only. In support of Mr. Anderson's claim, we may say in this connection that the comb honey of Idaho, so far as our experience goes, does not granulate readily.

GRADING COMB HONEY.

The question of grading-rules was given considerable attention. Mr. Muth, of Cincinnati, offered a set of rules which provide practically for only a fancy and a No. 1. No other honey, he said, ought to be shipped to market. Attention was called to the

fact that these rules, if adopted, would bar out a large proportion of all the comb honey produced; that there ought to be some means by which these lower grades could be described and sold.

Mr. G. F. Demuth, of the Bureau of Entomology, Washington, D. C., offered another set of grading-rules that differed radically from those presented by Mr. Muth. They were based on three definite points—namely, weight, finish, and color. The old Colorado grading-rules were based on a minimum weight of the case itself. The new Colorado rules, on the other hand, are based on a maximum and minimum weight of the section. He believed that this latter was the correct principle. His rules provided for three different weights, several grades of finish, including a fancy, a No. 1, a No. 2, and several shades of color. He recommended a scheme of colored cards that would enable the purchaser and producer to describe accurately the shade by a certain designation of color. The objection to the new Colorado grading-rules, said Mr. Demuth, is that they are not adapted to our Eastern honey. He would have the rules flexible enough so that they would take in Eastern as well as Western honey. He explained the system something as follows: In the matter of finish he would have extra fancy, fancy, No. 1, and No. 2. In the matter of weight he would have heavy, medium, and light. The finish would be designated by extra fancy, fancy, and No. 1 and No. 2. As for color, he would go by the color-card system. The three grades of weight, the four grades of finish, and the several grades of color, would make a variety of gradings. Here, for example, would be a section that he would grade as fancy, medium, white; or, for short, he would make it F. M. W., which would be marked in plain letters on one end of the case. Another case, for instance, would be marked No. 1 light amber, or be designated No. 1 L. A. Another case might be designated as No. 2, dark, heavy, or No. 2, D. H., and so on.

At the close of his general explanation Mr. Muth wanted to know if Mr. Demuth would hire a Philadelphia lawyer to make these discriminations. Both he and Mr. Weber expressed themselves decidedly as believing that such a system would be too complicated to be practicable—that with even the simple grades that have been in use, the average producer did not begin to grade in accordance with those simple rules. He hoped the complicated system advocated by Mr. Demuth would not be adopted. The latter explained that, although he was from

Philadelphia, his system was not as complicated as might appear at first sight. He wished to make it plain that the grading he proposed would take in any kind of comb honey—good, bad, or indifferent; that it would enable the producer to describe accurately what he had to sell, even though it were an off grade, and the buyer, on the other hand, to know just what he buys. He argued that one of the difficulties that arise between the producer and the buyer is the lack of some scheme to describe accurately the product under consideration. Both Mr. Weber and Mr. Muth expressed themselves as believing that such a scheme would be too awfully complicated to be of any use whatever. The rules were, however, adopted by the Association substantially as they were presented, except that the term "Standard" or "Choice" was substituted for the term "No. 2."

At the last session, after all the business had been transacted, and while the committee were out preparing a report, there was quite an extended discussion, covering the general subject of foul brood, over which Dr. Phillips presided. There being several foul-brood inspectors present, a report was rendered by each. The first was by Mr. Wesley Foster, of Fort Collins, Col., followed by Dr. B. N. Gates, of Massachusetts; Mr. Erbaugh, of Indiana; Dr. Ward, of Tennessee; Mr. Demuth, of Washington, D. C., and Mr. Cavanagh, of Indiana. The latter, while he is not a foul-brood inspector, has had a wide experience with European foul brood.

The discussion on this disease was interesting and valuable, because it showed the great importance of having vigorous Italian stock. But it seemed to be difficult to effect a complete cure with the ordinary black bees, in the case of European foul brood. The reports of all the men indicated that they were getting foul brood well under control. Not the least important thing in this inspection work was the information that the inspectors are able to impart, not only to those who have foul brood, but to those who have not.

An election of officers for the ensuing year resulted as follows:

President, Dr. B. N. Gates, of Massachusetts; Vice-president, Prof. H. A. Surface, of Pennsylvania; Secretary, E. B. Tyrrell, of Michigan.

The following were elected as Board of Directors:

E. D. Townsend, of Michigan; Wilmon Newell, of Texas; Wesley Foster, of Colorado; F. B. Cavanagh, of Indiana; J. M. Buchanan, of Tennessee.

Heads of Grain from Different Fields

The Folly of Using Small Rusty Tin Packages for Extracted Honey for the Retail Trade

Some large honey-producers are beginning to put up extracted honey in small tin cans or pails, when extracting in the late summer and fall, for the retail or family trade during the winter. Of course, this procedure is a more convenient and less expensive method than to put the honey into five-gallon cans, when extracting, and then later on perhaps remelt it and put it into smaller cans and pails for the retail or family trade.

But I happen to know a man who purchased, from two different extensive honey-producers, some of those self-same cans and pails, several months after they were filled, and some of them were the worst and toughest-looking honey cans and pails I ever saw. All looked as if they had been used before for some purpose, either for canned tomatoes or corn! In one instance they were all labeled with the producer's honey-labels; but the cans had become so rusted that the labels were loosening. In the other lot, while the cans or pails had not been labeled, they were rusted in spots, and were a "bum-looking" lot.

Now, no retailer of honey, nor any one working up a family trade in honey, cares to deliver it in what looks like second-hand cans. It is enough to discourage sales, as no nice clean housekeeper would want to buy honey the second time (nor the first time, for that matter) if it is put up in rusty containers of any kind, even though the rust is only on the outside.

If honey-producers are going to make a practice of putting their extracted honey in small tin packages at the time of extracting, then they should use only new bright cans or pails, and, after filling, store them in a practically dust-proof and very dry place, so that they will be kept clean, and also not rust. This is a very important matter indeed; for, some of these days, the honey sold in such second-hand-looking cans and pails is going to be *refused*—shipped back to where it came from, or held subject to the order of the shipper. And that would be simply what the shipper who will send out honey in such cans or pails deserves. No person who is endeavoring to work up a family trade in honey wants to deliver it in any thing but bright new tins, if he uses tin packages at all.

I think this is a matter worthy the attention of every producer who practices putting up his honey in the tin retail packages at extracting time.

Sandpoint, Idaho.

GEORGE W. YORK.

[Some of our old readers will recognize the writer of the foregoing as the former editor and proprietor of the *American Bee Journal* for so many years. He also did a large business in retailing and wholesaling honey in Chicago. He therefore speaks with a knowledge born of *experience*. He is entirely right in what he says.—ED.]

European Foul Brood and the Importance of Keeping a Strain of Italians that are Largely Immune to the Disease

You are lucky to have kept bees so long without having European foul brood. My experience with the disease is like that of Morley Pettit. It spreads to every hive in the yard, and to every comb that contains brood. Not only a few cells are affected, but less than half the young bees in a comb ever get out of the cells alive.

Dr. Miller's bees must have had the disease in a mild form, and then he had a hard fight and a long one; and he will be fortunate if the disease does not break out again next summer.

What I am most interested in now is to find a way

to get rid of the disease. I understand that when we brush the bees off the combs and put them in a clean empty hive and give them a new start they will start off free from disease; but some way they don't stay free. I understand, too, that when I take the queen away and keep the colony queenless till the young bees are all out of the combs, and the cells cleaned and polished ready for the queen, then put the queen back or give them another queen, the combs will soon begin to fill up with nice pearly-white brood; and I am not sure that the dequeening method is not as good as putting the bees into an empty hive; but about the next time I open the hive the white brood has turned yellow, and the disease is there again.

We are told to treat the bees when there is a good honey-flow on. White clover was abundant last year, but the flow did not come, and I worked at a disadvantage.

Oakland, Ill.

WM. COX.

[In some ways European foul brood is easy to cure and in other ways it is not. It seems to spread much more rapidly than the American type of disease, and, what is somewhat discouraging, the ordinary shaking process does not always eliminate the trouble. We have had a very large number of reports of how, after one shaking, the disease had returned again. We are coming more and more to have faith in the Alexander treatment; and that is, removing the queen and keeping the colony queenless and putting in pure Italian blood. There are some strains of Italians that are probably more immune to the disease than others. Mr. S. D. House, of Camillus, N. Y., has repeatedly told us that he has no fears of European foul brood, because he used a strain of Italians that would keep the disease off, and he has European foul brood among the black bees all around him, and yet his apiaries of Italians seem to be immune to any trouble of that sort.]

You do not say any thing about using Italian stock. While it is proper enough to remove the queen we think it is better to go even further, and put in good vigorous Italian blood. If possible, get a strain that will resist European foul brood—a strain that has been tried out and found to be equal to the occasion. We try to keep a strain of Italians that are immune to European foul brood. In all of our years of experience we have never had a trace of the disease.—ED.]

Overcrowding Bee-Ranges, and is there a Remedy?

I wish to ask about the law in regard to other apiarists crowding in on to one's bee-range. My neighbors and I started in this locality three years ago with our little bunches of bees. I have 25 colonies; the other neighbors of mine would bring the number up to about 75 stands—all our range will accommodate. Well, a few days ago another apiarist brought in 50 colonies of bees, and located them about 800 yards from my apiary, and is to bring in about 200 more colonies (so I am informed). What can I and my neighbor do about it?

Phoenix, Ariz., Jan. 20.

L. M. BROWN.

[You bring up the question that has often been discussed through the columns of our various bee journals, namely, the one of overstocking. There seems to be almost no remedy but a sort of unwritten law that prevails in some localities, not to put more than a certain number of bees to the square mile. Where the different neighbors and different beekeepers can get together and agree, they will divide up the territory in such a way that it will not result in overstocking; but very often outsiders come in and squat an apiary or two so close to bees already in the locality that the annual yield per colony is cut in two. There is no law in any State, with which we

are familiar, that regulates the number of bees that may be kept within a certain territory, and it is doubtful if any law would be constitutional if it were passed. The only thing we can suggest for you to do would be for you and your neighbors to go and visit these parties and explain to them that the locality is already overstocked; show them that, when so many bees are put in a place like this, it usually cuts down the yield; that it would be unprofitable for them as well as for you. The cost of moving bees from one locality to another is so great that the average beekeeper, if he looks to his own interests, will find some place where it is not already overstocked. The same problem that confronts the beekeeper around Phoenix and Tempe, Arizona, confronts the beekeepers in various parts of the West where alfalfa is grown very largely. We know of many localities in the West that formerly yielded anywhere from 100 to 200 pounds per colony; and now those same localities will not furnish more than 25 to 50 pounds per colony, simply because so many beekeepers have located in the territory that the yield is cut down. This policy results in a freeze-out game. After a few years the less successful will go out of business, or, rather, they will quit keeping bees or sell to their neighbors who are more successful, with the result that, in time, there will not be many more bees than enough to take care of the territory properly. No, there is absolutely nothing you can do except to use diplomacy of the finest sort, and moral suasion.

There is one thing that you can do: If these people who come in to your locality are bringing in diseased bees, they can be stopped. Go to your foul-brood inspector and have the bees inspected. If they have disease they will have to be removed or treated immediately. Most States have a law now by which it is unlawful to ship diseased bees into the State. Where you can learn that such shipments are contemplated you can have the inspector on his watch and have the bees stopped and examined before they come inside. Come to think, however, Arizona has no foul-brood law, so that you really have no recourse of any sort except moral suasion.—Ed.]

Requeening to Prevent Swarming; Does a Capping-melter Make a Room too Warm to Extract in?

Can you advise me of any beekeepers who dequeen their colonies to control swarming? I have heard that some beekeepers remove all queens at the approach of the swarming season, holding them in a nucleus for a time, and returning them in about 10 days.

I have seen the description of the new capping-melter. Does it throw very much heat when in use? We have always been afraid that we couldn't stand the heat which would come from it. Could a gasoline stove with an elevated tank be used instead of the coal-oil stove? Please advise as to how much floor space the capping-melter occupies.

Wooler, Ont., Jan. 23. WARRINGTON SCOTT.

[The practice of dequeening a colony to prevent it swarming is not so common as it was a few years ago. It works in a few cases with ordinary Italians; but in a yard of Carniolans that we tried out last summer it absolutely failed to do the work. The Carniolans swarmed out with their virgins, and made us no end of trouble; and if they had no virgins they would unite with some swarm in the air. One objection to dequeening to prevent swarming is that it takes the life and energy out of a colony. One with a queen will be much more active than one without, as a rule. We do not know of any one now who is practicing that method of swarm prevention.

Regarding the capping-melter, the board in the table is 4 feet long, 2 feet wide, and stands 29 inches high; and the pan is 18 inches wide and 3 inches

longer than the table, so that it projects at one end to hold the knife, so that the uncapping-knife can be dipped in hot water.

You ask whether this machine with the stove will heat up the extracting-room. A good deal will depend upon the size of the room. If it is of sufficient size to work to advantage, and there is plenty of ventilation, you will not notice this extra heat; but if the room is small, and only a single-thickness wall, and exposed to the sun's direct rays, on a hot day you will find the capping-melter rather warm to work over. If you are in a position to get an electric fan it will cool the room and keep it very comfortable while you are working. If there is no electricity, it is very easy to rig up a little fan in connection with the extractor. A gasoline-stove with an elevated tank can be used, provided the pipe is extended a foot or so, horizontally, so as to be out of the way of the melter.—Ed.]

Good Bee Locations in Oklahoma and Kansas

If you were to choose a location where you could branch out in the bee business and make the production of honey your only business, where would that location be? G. M. WHITFORD.

Arlington, Neb., Jan. 20.

[The question propounded above is a rather hard one to answer. There are many very fine locations in the United States that are not already occupied; but there are many other good locations that are already overstocked with bees and beekeepers. Some splendid locations have been utterly ruined because with too many beekeepers in the locality it injures the business so that there is no profit in it. There are many good locations in semi-arid regions of Oklahoma, Kansas, and Nebraska. In these States it is advisable to locate in a valley along some stream, and we would not go into the bee business very heavily anywhere unless the alfalfa or some one of the clovers can be grown quite extensively in the locality. There are many places in Oklahoma and Kansas, for example, that have almost no bees, and yet where alfalfa is grown. In such locations there are some splendid opportunities for the keeping of bees. The business perhaps is more profitable in the irrigated regions where alfalfa is produced; but one difficulty in such locations is that the field in most cases is already overstocked with bees and beekeepers. We find, however, that there are many locations in semi-arid regions where there are practically no bees kept. While the alfalfa does not yield as well, perhaps, in what is called the dry-farming districts, yet it yields enough to make the business very profitable, providing enough colonies are kept. We do not care to indicate any particular locality, but would suggest that you make a tour through northern Texas, Oklahoma, and Kansas. There are many splendid locations in your own State; but be careful to find some place along the rivers and creeks, especially in the valleys. High land is not as good a place to grow alfalfa in a semi-arid State as in the valleys.—Ed.]

Little Mortality Around Cincinnati

Bees are wintering perfectly here on their summer stands—very light mortality; less than a handful to each hive. Bees had five flights during December, and nine so far in January, as follows: Jan. 1, 2, 6, 18, 19, 20, 23, 25, 26. Has any one ever seen similar conditions? Colonies will surely come through the winter exceptionally strong, and they were packed with stores late in the fall, so there is hardly any likelihood of starvation. White clover is very abundant; and unless all signs fail, we will have a fine honey year in 1913. In this locality, bees will start gathering pollen about March 1. I have 11 colonies in good condition in my back-yard suburban apiary. Cincinnati, Jan. 27. ALBIN PLATZ.

Our Homes

A. I. ROOT

For I the Lord thy God am a jealous God, visiting God.—MATT. 5:8.

God hath said, Ye shall not eat of it, neither shall ye touch it, lest ye die.—GEN. 3:3.

For the Lord thy God am a jealous God, visiting the iniquities of the fathers upon the children unto the third and fourth generations of them that hate me.—EX. 20:5.

I want to talk this morning particularly to the young men and young women who are in the habit of reading these Home talks. My talk will also be to the middle-aged; and, before I close, I shall have something to say to the elderly ones, the ones whose hairs are beginning to get gray. I suppose most boys and girls, especially as they reach maturity, begin to think of this matter of *getting married*. It is sometimes true that the girls especially talk so much about getting married that they don't have room or time for any thing else. This is not just the right and proper thing to do; but it is true that both boys and girls should consider that God gave each one of us a human life to live with the thought in view that we should be "fruitful, and multiply, and replenish the earth;" and, in fact, I have touched upon this matter several times in these Home papers, of the damage that can be done to humanity by the offspring that, in the course of years, come from a single pair of men and women who are viciously inclined. On the other hand, we have many instances of how the world has been greatly blessed by a long line of people who *feared God* and loved humanity, and who have handed down their lifework to children and grandchildren until the world will scarcely ever know how much benefit has been conferred on humanity by the fact that they not only lived a good life but reared up boys and girls to follow after them along in the same line. Now let us take it for granted that most boys and girls expect to get married some time; that they expect, God permitting, to have a family of children. Now, my young friends, what *sort* of children do you expect to rear up and bless (or curse) humanity? I need not tell you how much time is being devoted now, especially in our agricultural papers, to this matter of selecting and rearing improved stock and planting good seed, which is along in the same line. Take the poultry industry, for example. How much time and money are being expended in getting a good strain of fowls whose eggs can be sold for not only a dollar apiece, but *ten* dollars apiece, and sometimes even more than that? In order to get a good parentage to start, no stone is left

unturned. On page 605 of GLEANINGS for September 15 we had a vivid illustration of how much pains the government of the United States is taking to stamp out injurious insects and things of that sort; and our attention is now called to the fact of how little is being done to improve the race of boys and girls and men and women.

Sometimes in talking with hardened criminals in our jails I have asked the question, "Would you want to see a boy of yours doing exactly as you have done?" The answer invariably comes, "God forbid." Even a hardened criminal has some scruples about seeing a *child* of his follow in the footsteps of crime. Now, my young friend, let us get back once more and ask the question, "What kind of boys and girls do *you* propose to give the world?" The Bible says, and our agricultural and poultry papers say, that like produces like. If you give way to vicious and impure thoughts, your boys and girls will be likely to do the same. The Bible tells us that this work *must* go on until the third and fourth generation. By the way, I have at different times heard critics find fault most severely with this passage in the Bible. It is repeated *four times* in the Old Testament, if not more. They ask what justice there is in punishing innocent children for what the parents did before they were born? My good friends, let me call your attention to the fact that God does *not* do this punishing. The father and mother do it themselves, and with the plain statements of the Scriptures before them; they do it with their eyes open; they do it deliberately and willingly. I once knew of a man who was an illegitimate child and part negro. He inherited his father's intellectual abilities and became quite a scholar. When he was grown up he said something like this: "My father deliberately cursed every single day of my life by giving way to a low, beastly impulse and passion. He did that almost in a single *moment of time* that has blasted every hour and almost every minute of my whole life."

Listen to this: A good mother, a good and wise mother, whom I know full well, once went along with her boy while a party were visiting the county infirmary. After they got home this bright boy, who had already begun to inquire into "cause and effect," asked his mother the question how it came that there were such a *lot* of people who were imbeciles and idiots. How does it come about we have such fearful

exhibitions of wrecked humanity? and why are there so many of them in almost every county? This wise mother might have told him just what was one of the greatest agencies in bringing this about. But I do not know but she was wiser still when she pointed him to one of the texts that I have chosen at the head of this paper. Come to think of it, I do not know after all that she called his attention to the text. I do not know what words she used, but it was something to this effect, and the boy has never forgotten it, even though now he is a grown man. The mother told him at least a large part of the idiocy and imbecility came from breaking a holy command that God has not only written in his word, but has implanted in the heart of every child of humanity, more or less. Let me digress a little right here.

From the time we come into this world until we step out, dangers beset us on every side. The babe is only a few months old when it reaches out its hands to the hot stove or to the candle, and is told, "Burny! burn! Mustn't touch it," and so on through life it has to learn. Sometimes when it is all by itself it thinks it will try the experiment and *see* what the consequences will be, and, sure enough, the little tender finger is burned, and it gets a lesson in the way of punishment. Eve told the tempter that God said they should not only refrain from eating of the tree of knowledge, but that they should not even "*touch it*."

My dear friends, there are things in the make-up of all of us where danger lurks near, whenever we even so much as touch the forbidden thing. Not only has God's holy word forbidden our touching it, but our consciences that he has implanted within us to tell us when we are getting over on to the danger ground. None of us know exactly, but it has always seemed to me quite probable that God proposed, in his own time—that is, when Adam and Eve arrived at the proper stage of human life—to make known to them all about the fruit of that tree, the tree of the knowledge of good and evil; but, as I have said, we don't know exactly about this. We *do* know, however, that God has planned, when we are fully matured, to give us knowledge that would be hurtful and dangerous to childhood and early manhood and womanhood. If you want to live to a good old age, and if you want to enjoy to the fullest extent every year of your life, let me urge of you to cultivate not only pure actions and words but pure thoughts. "Blessed are the pure in heart, for they shall see God." This one beautiful text covers the whole of it; and

you *know* when you are pure in heart (when you permit other than pure thoughts to enter your mind) better than anybody can possibly tell you. Sometimes parents excuse their sons by saying the young man is sowing his wild oats, and that in due time he will get over it and come down steady and honest. Perhaps the word *honest* is not just the one I should use here; but I think, after all, I will let it remain. Suppose he does get his crop of wild oats sown, and settles down honest and steady, and marries a good girl. Do not those wild oats, sown long ago, bear any crop? My dear friend, the crop is the one I have mentioned in the infirmaries, poorhouses, and insane-asylums in this land. Do you want to contribute to such a crop? Whatsoever a man soweth, that shall he also reap.

God has wisely planned to arrange so that the best years of every man and woman shall be used for the production of offspring. If you want to make a good contribution to humanity, it is not wise or well to commence too early in life. Wait until you are *fully matured*. In the same way it is not wise nor good sense, in ever so many ways, to delay the matter too long; in fact, God has placed a limit to motherhood, and I have sometimes thought he ought also to have placed a limit on all. I *do* know that old men frequently, after having given up the cares of life, perhaps moved into town and settled down to take things easy, still allow thoughts to take place in their minds that should be put away and forgotten *for ever*. I have known friends of my acquaintance who have gone to the insane-asylum, I think just because they gave up work and persisted in indulging in things that ought to have been put away long ago. If you want to live to be a hundred years old, if you want to have the full use of the powers of both mind and body, do not, I beseech you, ruin yourself, both body and soul, by letting selfish and ignoble feelings have any place in your thoughts or actions or life. I feel quite confident that there are people whose eyes rest on these pages who have had glimpses of the insanity and imbecility that come right along the very line on which I am talking. Perhaps they heeded the warning that God sent, for I feel sure it *is* God himself who does send such warnings to turn us back into the straight and narrow path. The very first pages of the Bible tell us that man was created in God's own image, and we are told in the back part of that same holy book that we are designed to be temples of the Holy Ghost. How can the Holy Ghost have any place or any perma-

ment abode in a body that is filled with things that are abhorrent to every honest and enlightened conscience? I am afraid that many physicians, or at least a large part of them, are not plain-speaking and honest enough to tell people who come to them just *where* the trouble is. Sometimes

I am sorry to say that these same physicians, especially if they are not *God-fearing* men, are making such a poor record *themselves* along the line that I have been speaking of that they have not honesty and consistency enough to tell the patient who comes to them where the real trouble lies. We are just now being informed through all classes of periodicals that the saloons of our land are the hotbeds of every sort of iniquity along in the line I have been discussing. Their business extends from the "white-slave traffic" to the work of spreading indecent pictures and literature in such a way that they may fall into the hands of our children.

In closing let me submit a letter from a good brother who has had much to do in inducing me to take up this line of talk at this present time.

Dear Brother Root:—In the first place I wish to give you (The A. I. Root Co.) a little bit of encouragement. I never knew any company engaged in a secular business that took as much stock in spiritual things as your company does. Sometimes I have wondered if the different members of the company were a unit in the good work. Again, I have caught myself asking the question, "How long will they keep it up?" But be that as it may, I hope that in this thing you may "abound more and more," for indeed it is a praiseworthy thing. I simply can not find words to express my appreciation of the spiritual part of your journal, and Our Homes beats any thing I ever saw outside of a religious paper, and if any one were not in sympathy with the religious part of your work the other is so good that he will take your publication any way—or at least it seems to me it would be that way in many cases. I think from one end to the other GLEANINGS has the cleanest set of writers I ever read. I am not saying this to puff you up, for indeed once in a while I see expressions that I think should not be there.

There is one thing, however, where you have not sounded the warning as much as its importance demands. When I think of my boyhood days and remember how many of my playmates and others that I knew are in their graves, and still others who have been in the insane-hospital, and that there are but few strong ones among all the living, and remember, also, their vices, my heart is filled with an inexpressible something. I well remember young men that were so weakened by the solitary vice (or by visiting places of ill fame) that they had no reserve vitality. I remember that when some of these would occasionally get drunk, good people would point to them and say, "See what drink will do." But the *real* cause was never, or at most very rarely, spoken of.

As I have followed some of my playmates to the grave, and have listened to the insane chattering of others, and knew the *real* cause, my innermost soul has cried out for some one to warn the coming generations. This is all true, notwithstanding the

neighborhood in which I was brought up was exceptionally moral. I can not tell all the particulars of how it came about, but let me say this: A bad boy visiting or sojourning in a neighborhood can and will do an incalculable amount of damage; and one family of youngsters spending the night with the young people of another home while the parents are away (or without the proper oversight if they are at home) is a most opportune time for the *de stroger* to get in his work.

And now, Bro. Root, if the enemy got in such deadly work in this way, in that day, in a community above par in morals, restraint, and carefulness, what must be the awful harvest in the near future where the young "just grow up" as they do in so many places to-day?

I often shake hands with some mere boy with signs of debauchery plainly written on his face; and how my soul longs to pour out itself in a helpful way to him! But if you have ever tried it you know how hard it is to say the right thing in the right way.

I am writing these things hurriedly, and you may have to read between the lines to get all I should like to have you get, and, again, you may not have seen the dreadful realities of these things as I have, and think I am *overdrawing* them; but "I know whereof I speak." I have been in a position where I saw cause and effect—saw the cause 30 years ago—some more, some less, and have watched the effect as some went to the grave, some to insane-hospitals, and some to a more or less wrecked manhood. I have observed, too, that so many children start in life handicapped, suffering for the sins of their parents, without vitality enough to carry them very far out into the sea of life.

But may be I had better change the subject; for if I get started I may not stop soon. But just one word more: A little over a year ago while talking to a mother in the south part of the State in regard to the "white-slave trade" and kindred things, she said, "I aim to raise my girls right," and she meant it too; but I thought to myself, "Whom will they mate with?" Isn't it *awful* to raise girls up right and then have them mate with some depraved or "disease-ridden" man? It seems to me just now as if you may have something to say on these things in your Home talks.

A COMPASS WITHOUT MAGNETISM.

The following, from a nephew of A. I. Root, explains itself:

Dear Uncle:—As I am rather near you at present I will drop you a line. I am in good health, and also very busy, as this is a brand-new ship and needs lots of work. I am a gyro-compass man now, on board this ship. It is a very interesting instrument. I wish you could see it. It is a compass which has no magnetic effect at all. It is run by electricity—a motor which runs 8600 revolutions a minute, and runs in a vacuum. If I can get a folder on it I will send it to you. It was invented by a man by the name of Sperry, 216 William St., New York.

HOMER H. ROOT.

U. S. S. Arkansas, Key West, Fla., Dec. 21.

We clip the following from the *Cleveland Plain Dealer*:

APPROVES GYRO COMPASS; NAVAL EXPERTS CALL IT BETTER THAN MAGNETIC.

WASHINGTON, Jan. 24.—Battleship tests with the new gyroscopic, or "battle," compass, reports to the navy department to-day announced, have demonstrated that it not only is a vast improvement over the magnetic compass but that it will pay for its cost and installation within two years in the amount of coal saved. This saving would be accomplished by,

cause a steadier course can be maintained by the use of the new compass, and therefore changes in speed to regain headway would be greatly reduced.

"The gyro compass is not yet wholly satisfactory, mechanically," the report confesses; "but when the remaining defects have been corrected, and it is capable of standing up to its work for long periods,

its installation on all capital ships will result in greater coal economy and in more satisfactory handling of ships."

"This last-named advantage," the report concludes, "would be especially gained when warships are steaming in squadron or were engaged in formations or evolutions."

Poultry Department

INDIAN RUNNER DUCKS; WHY THEY DON'T LAY, AND WHY THE DUCKLINGS DIE.

Mr. Root:—Will you please tell me why my Indian Runner ducks are not laying? They have not laid in almost three months. Can they be picked? My little ducks all die. What do you feed them?

Parish, Fla., Dec. 26. MRS. H. L. GILLET.

My good friend, I don't know that I am exactly competent to answer your inquiry. All the Indian Runner ducks I have ever kept have always laid more or less. I have had no experience in picking ducks; but I understand through the poultry journals that where you want to get eggs you must not take off the feathers. The ducks can not very well furnish a crop of feathers and a crop of eggs at one and the same time. I feel sure your trouble about the ducks not laying is in the feed. Ducks must have either soft food or else grain soaked in water. I have explained several times that I feed all my corn and other grain in a tub half filled with water. This accomplishes two things. It gives the ducks the moistened food as they need it, and water with their food, and at the same time it prevents rats or other vermin from helping themselves to the grain. Our laying ducks are fed mostly on corn and a little wheat with the corn; but as they seem to prefer the corn, that is the principal part of their diet. Now, I would vary this diet were it not for the fact that they go out in the canal every day from eight o'clock in the morning until about four in the afternoon; and in the canal they get a great variety of animal food and vegetable food along the banks. We have always fed our ducklings and little chickens bread and milk for the first three or four days, or say a week, and this milk has furnished the needed animal food. A very important thing for little ducks, and I think little chickens also, is to give them green vegetable food; and as they seem to prefer lettuce to any thing else, I would try to have some lettuce leaves ready for them when they are two or three days old. The bread and milk, of course, gives them a certain amount of animal food; but when we take a hatch off the incubator there are more or less infertile eggs, and eggs at the close of the hatch that are only partly developed. These are all boiled, and I give the little brood say an

egg a day, cutting it up fine at first to teach them to eat it. I should have said that the lettuce is also cut up in little bits until they get an appetite for it. After both ducks and chickens have learned to eat lettuce you will find that they will leave any other food when the lettuce is offered them. Some have objected that bread and milk is a rather expensive diet, especially where there are very many chickens.

Now, here is something I want to tell you all. I have had it in mind for some time. One of our bakers here in Bradentown has considerable stale bread; and especially is this true Monday morning. With the agreement that I take it off his hands, he lets me have it at the very low price of a cent a loaf. On one occasion, when he had had bad luck with his yeast or his "rising," there were over a hundred loaves that I got for a cent apiece. Now, the poultry journals advise that the bread and milk be made by first toasting the bread or drying it in an oven until it is hard and brittle. When you are ready to feed them, pour a little boiling water on it, which quickly softens up the bread. Then mix it up with milk. This baking is especially important when the bread is very old, because the strong heat kills all sorts of germs that might have been deleterious to the chicks. After the chicks or ducklings are a week or ten days old we mix in gradually a little bran and middlings, and finally their mash is bran and middlings alone, perhaps adding some Indian meal. On one occasion, when I was obliged to be absent, I left some little ducks in Mrs. Root's care; and as she had not paid very much attention to my duck experiments she gave them chick food as you do chicks; and before I got around home several of them had died. Now, this fact should be kept in mind—that ducks can not digest their food unless they have water with it. You will notice they first take a bite of food and then a drink of water, and so on alternately. When they are given dry grain some distance away, I have seen them run hurriedly a good many rods to get a drink of water, and then come back again after their grain. Running water, if possible, should be provided close by where they get their food. They can then help

themselves to their oft-needed drink. The ducklings can be fed wheat, provided it is soaked so as to be soft, after they are two weeks old. You have probably noticed that both ducklings and chickens when they become accustomed to one kind of food get it into their heads that they can't get along with any thing else, and there will be quite a little teasing if they don't have their accustomed diet.

In regard to animal food for ducks, in one of Cypher's catalogs he gives illustrations of two flocks of ducks. One had plenty of animal food from the start, and the other had nothing but vegetable food. Both flocks of ducks were hatched from the same eggs, the same in number; but at the end of several months the number of vegetarians had been greatly reduced, and they did not compare at all favorably with those that had the meat diet. From this it seems evident that ducks especially must have a considerable amount of animal food in their ration. If they do not they will suffer. Another thing, we want to be sure that they have plenty of fresh air. I think many chickens and ducks are killed by artificial heat when such heat is not needed. With what experience I have had with ducks I should say that they are the easiest fowls in the world to raise. From all the ducklings I have brought to successful maturity down here in Florida, I can remember only one that died unless it was by accident. Give them an enclosure when they are little, where no rat or wild animal of any sort can possibly get to them, then let them have their liberty, and run and enjoy life and be happy.

Just before dictating this I went out and had a look at my twelve ducklings hatched out by an Indian Runner mother, and it is wonderfully interesting to me to study a sitting *duck* and her habits and ways of managing, as well as studying a sitting hen.

POULTRY-NETTING BASKETS FOR FEEDING CHICKENS GREEN STUFF, ETC.

Since what I have said in regard to this I have made another big discovery. Listen and see if you do not agree with me. After what I said about rolling up a piece of poultry-netting, something seemed to keep saying to me that I had seen a basket somewhere that was just the thing, that we had already in use. Finally, one day in going through one of our store rooms I saw some poultry-netting hens' nests hanging up on a nail. These were bought from Sears, Roebuck & Co., at a cost of only 4 cents each, and they had never been used because they are almost too conspicuous to please the

"biddies" unless they are screened by a box or something of that sort, to make them more retiring. As I never got around to do this they remained there unused. In a twinkling I had twisted some wires around the upper edge to hang them on the poultry-netting fence, and they made just the prettiest baskets for holding lettuce and green stuff that can be imagined. In your garden you frequently have lettuce, radishes, turnips, and mustard sown too thickly. Well, when you pull out the surplus plants and throw them on the ground the chickens will just drag them around without being able to pull off the leaves so they can eat them. With this wire-cloth basket the thing worked to perfection. Put any old outside leaves from cabbage, lettuce, turnip tops, etc., from the kitchen, and all such stuff, into these baskets, and it will be eaten up perfectly with scarcely a remnant. With our convergent poultry-yards we simply hang the baskets on the outside of the fence clear around the circle; then, in order to feed the chickens green stuff, we do not have to open the gates at all. Just go around with your basket of lettuce, or other green stuff, and drop a handful over into the hens'-nest basket, and it is done in a twinkling. For little chicks, of course, you have to hang them lower; and it is one of the prettiest sights I ever saw in the poultry-yard to see an incubator flock of chickens busy at work at a great head of lettuce suspended just over their heads in one of these baskets.

While on the subject of these wire-cloth baskets I want to say that a poultry-netting *bottom* for any hens' nest is certainly a very fine thing. While visiting our Ohio Experiment Station I noted that their trap nests were all made with poultry-netting bottoms. This let all accumulation of broken straw, chaff, etc., drop down through out of the way. And, by the way, about the best material for hens' nests that I know of is soft hay. Our Bermuda-grass hay that grows down here in such profusion is just the thing. As often as the hens break it up and let the fine part drop through, some more fresh hay can be supplied. In this way the nests are always nice and clean and sanitary.

I want to say something more about lettuce. About three miles south of us is a young market-gardener who has several acres of perhaps the most beautiful lettuce that I ever saw. Well, a few days ago he told me that if I would come down with my auto and get it I might have all the lettuce I wanted. That is, by selecting heads that were not fit for shipment I could probably

get all my fowls could consume. Accordingly I went down, and almost immediately after feeding plenty of lettuce in these wire-cloth baskets we had a great increase in eggs. One reason for this is, perhaps, that my chickens hadn't been getting *enough* green stuff, or such green stuff as they particularly preferred; and I find, by experiment, that there is nothing in the *whole round* of vegetation that pleases chickens like the nice head lettuce grown here in Florida. They will not only leave the grain but they will leave the meat scraps from the butcher's in order to get this lettuce, and just the sight of the great nice heads of lettuce seems to set them to singing. In fact, as soon as they see me approach with a big bundle of lettuce they all run for me as they do for nothing else. I believe it would abundantly pay every poultry-keeper (at least on any considerable scale) to grow lettuce especially for his fowls. Mustard may answer just as well, or better, on account of its pungency; but I haven't been able as yet to ascertain this fully. But the wire-netting baskets I have been speaking of are certainly the finest things in the world to feed mustard leaves, or leaves of any thing else, for that matter. The lettuce mostly grown here for shipping to the northern market is what is called the "Big Boston." This makes heads like heads of cabbage; and even the smallest chickens, when only a few days old, will learn the trick of eating out every particle of these large heads, especially if they are placed for them so they can get at them like the poultry-netting hens' nest I have been describing. I presume you can buy these hens' nests at almost any hardware store, but perhaps not quite as cheaply as the price I have mentioned. The little Indian Runner ducks seem just as greedy (if not a little more so) for the lettuce as do the chickens; and I am sure it conduces very largely to their health and growth. Aside from the egg-laying and the increased health by the use of plenty of lettuce, it is worth a good deal to have something that will make your wild untamed fowls tame and good-natured—even the crazy Leghorns that attempted to run clear off the premises without any adequate provocation. When they come to learn to eat lettuce they will get around you and become tame in short order—that is, after they once get a taste of the lettuce they seem to value so much.

HENS' NESTS; IMPORTANCE OF SHADE.

By the way, there is one serious objection to the hens' nest that I pictured last summer when I was describing and planning the convergent poultry-yard. The nest, as

I have it, is all right during cloudy days; but when the Florida sun comes down very hot on those sloping roofs it gets so warm inside that the hens go somewhere else to lay their eggs; and their old nests that were previously provided for them under the roofs where they roost at night seem to be much preferred during the hot days, especially in hot weather. There are two reasons why I don't like a hen's nest on the ground. First, the hens seem to like to climb up to some place to lay their eggs, perhaps to get away from "varmints," and also have some privacy; and, secondly, it is hard work for an old man to go around to very many nests and stoop over every time. When the nest is raised up a convenient distance from the floor this is done away with. The nests should be of easy access to both the hens and the owner. The nests should also be dark; for I am satisfied a dark nest is a great preventive of the habit of eating eggs. Besides, a hen on the nests greatly prefers to be where she is not easily seen by any one who happens to pass by. I would have the opening whereby she gains access turned back the other way from where the attendant is likely to pass.

SOME MORE "STRAWS" THAT "SHOW THE WAY THE WIND IS BLOWING."

The following clippings from the *Baltimore Sun* show progress surely. Behind the bars is the proper place for a drunken chauffeur. Long live Gov. Sulzer.

BAN ON DRUNKEN CHAUFFEURS; GOVERNOR SULZER SIGNS BILL PROVIDING FOR THEIR PUNISHMENT.

ALBANY, N. Y., Jan. 16.—"I don't think we ought to countenance drunken chauffeurs. Sober ones have hard work in dodging pedestrians."

Thus spoke Governor Sulzer to-night as he signed his first law as Chief Executive of the State. The new law provides one year's imprisonment or a fine of \$500, or both, as punishment for an intoxicated chauffeur operating a car.

A FREIGHT-CAR CONDUCTOR QUOTED AS SAYING THAT TWO-THIRDS OF ALL RAILROAD WRECKS DUE TO NEGLIGENCE ARE CAUSED BY DRINK.

TO THE EDITOR OF THE SUN—*Sir*: In his admirable letter on railroad accidents published in to-day's *Sun*, Mr. Torsch fails to mention the most frequent cause, to wit, drink. A freight-car conductor said to me yesterday that two-thirds of all wrecks resulting from mistakes or negligence were really caused by drink. He said he had seen many wrecks; and, with the exception of those caused by broken rails and wheels, they were nearly all caused by drink.

By drink he did not mean drunkenness, which is a rare vice nowadays among railroad men, but that lethargic state of mind which results from so-called moderate drinking, and which is produced in some men by one drink of liquor. He said there is little drinking among railroad men while on duty, but there is nothing to prevent them from coming to their work after taking one or more drinks.

VOL. XLI.

APRIL 1, 1913

NO. 7

Editorial

At the Cincinnati National convention, Secretary Tyrrell either mislaid or lost his memorandum-book in which he had taken a number of subscriptions to the *Beekeepers' Review*. He desires that all who gave him such subscription write to him, giving their names and addresses. Address E. B. Tyrrell, 214 Hammond Building., Detroit, Mich.

SOMETIMES beekeepers in California and other western States are inclined to poke fun at the "one-horse" beekeepers of the East. A great many of these Westerners will have to take off their hats to one beekeeper of the East, or more correctly of the Southeast, Mr. J. J. Wilder, of Cordele, Ga. He has over two thousand colonies in thirty-nine different apiaries, and in 1912 produced one hundred and twenty-five thousand pounds of honey.

WASHING CLOTHES IN HONEY.

WHILE visiting in Oklahoma we learned how one of the early pioneers in that State was in the habit of washing her clothes in honey. We suppose the honey was of inferior quality; but the washwoman explained that the honey would remove soiled parts and dirt equal to or better than soap. We presume, of course, that after the clothes have been soaked and washed in honey they were then rinsed in water.

DEATH OF OLIVER FOSTER.

THIS occurred March 12, as the result of a complication of stomach troubles and pneumonia, at his late home in Boulder, Col. Mr. Foster was an uncle of Mr. Wesley Foster, our Colorado correspondent. Years ago he was more of a contributor to this journal than he has been of late years; but he had a genius for inventing things; and the old volumes of *GLEANINGS* as well as the *A B C* of Bee Culture will show that he was a pioneer in the use of some ideas that are now common. We hope to have a fuller sketch of him later, written by his nephew, Mr. Wesley Foster.

A FOUL-BROOD BILL PENDING IN MINNESOTA.

A BILL creating the office of State Apiculturist, providing for instruction in beekeeping, and for the suppression of contagious diseases among bees, and appropriating money therefor to the amount of \$8000, has been introduced into the Minnesota legislature as House file No. 882, by Representative Frank Hopkins, of Renville Co., and Senate file No. 701 by Senator Murray, of Renville Co. Every beekeeper should write to his Senator and Representative at once, urging them to give the bill their support.

OUR COVER PICTURE.

OUR cover picture for this issue is appropriate in that it gives a glimpse of the outfit used by one of our California correspondents, Mr. M. H. Mendleson, for taking care of extracted honey. Notice that the honey runs by gravity from the extracting-house into the large tank, from which it is drawn later into the 60-pound square cans regularly used. A supply of these is shown stacked up in the foreground. Wherever the extracting-house may be located on a hill-side, so that advantage may be taken of the natural fall for the gravity system, the plan has much to commend it, for it is simplicity itself. The roadway should lead to the lowest point for convenience in hauling away the honey.

A NEW BEE PAPER IN CALIFORNIA.

THE *Western Honeybee* is to be the name of a new bee journal published in California by the California State Beekeepers' Association. Mr. Geo. L. Emerson, of 3497 Eagle St., Los Angeles, Cal., will be manager and probably editor. The California Beekeepers' Association was never in a more flourishing condition than it is now. There are six hundred members, and the membership continues to grow. For some time there has been felt a need for a special bee paper to present the interests of the California beekeepers, and the time now seems ripe for launching the new paper. It

will appear about April 1. GLEANINGS welcomes it into the field, and sincerely believes that it will do a large amount of good on the western coast.

HELEN KELLER, THE BLIND DEAF-MUTE.

THIS wonderful girl recently delivered an address before a thousand people. The wonder of wonders is that, with apparently no means of communicating with the outer world, she is now able to talk, write, sing, play the piano—in fact, do every thing that we all do except see and hear. Play the piano! how is it possible that one can produce strains on an instrument that she can not hear? But GLEANINGS has more than a common interest in Helen Keller. She wrote a short article for it (p. 844, 1891), when she was about eleven years old. If we are right, GLEANINGS was one of the first to publish her letters, and since that time her fame has gone around the world. Her picture appears on page 463, 1891, with much information concerning her.

LOWER FREIGHT RATES FOR HONEY IN NEW SOUTH WALES.

FREIGHT rates on honey in New South Wales have been lowered, as the honey now goes as Class A, the rate of which is lower than Class B. There is no distinction made between honey in comb, in glass, or in tin, as shown by the following clipping from the *Agricultural Gazette* for September 2:

The Chief Commissioner for Railways has approved of the charges for the conveyance of honey by rail being reduced from "B" to "A" class rate and conditions, and the necessary by-law has been forwarded for the approval of the Executive Council. This means that for the future the rates per ton will be as follows, two tons being the minimum:

Miles	50..	Rate per ton....	\$1.60
Miles	100..	Rate per ton....	2.88
Miles	150..	Rate per ton....	3.90
Miles	200..	Rate per ton....	4.84
Miles	300..	Rate per ton....	6.34
Miles	400..	Rate per ton....	7.34
Miles	500..	Rate per ton....	8.34
Miles	600..	Rate per ton....	9.34

It would seem as though there would be a difference between the rate on comb honey and on extracted, though no mention is made of it in the above. Will some one from Australia please explain?

SOLID VS. SCREEN DOORS FOR HONEY AND EXTRACTING-HOUSES.

A CORRESPONDENT in this issue recommends the use of a solid door in place of a screen door to the extracting-house. He is entirely correct. Others have called attention to the importance of the same thing. A solid door that is used for constant ingress and egress should, of course, be kept

closed. Ventilation should be secured by screens at the windows. The robbers that will cluster on the window screens will have no way of getting in; but robbers on the screen door, every time it is opened, will pounce into the building. There are some extracted-honey producers who contend there should be no bee-escapes on the window screens—that the robbers trapped within the building should be held in until the work is done, and then released when they can do no harm to any one at the close of the day. If they are professional robbers, they make it a practice to let them starve to death, because, if released, they will continue to make themselves a nuisance.

INDOOR WINTERING AT MEDINA; BROOD-REARING IN CELLARS.

WE went into winter quarters last fall with something like 600 colonies. About half of them were wintered outdoors, and the other half in cellars. So far the loss all told does not exceed one per cent.

In GLEANINGS for February 1, page 73, we reported how we moved on a sled some ten miles one of our outyards during the dead of winter, when the temperature was only 15 degrees above zero, to one of the cellars. Prior to that time we had moved in two other yards and placed them in the same cellar. All the moved lots of bees seem to have wintered equally well so far as we can discover; but we have taken out only half of them, especially those that began brood-rearing in December and January. The remarkable thing is that many of the colonies are stronger this spring than they were last fall. Ordinarily there is not much brood-rearing in the cellar; but the late moving possibly stimulated the bees to breeding earlier than usual. Well, we were a little fearful that so much brood-rearing would prove disastrous toward spring; but, so far as we can see at this time, no bad results have followed.

There was one weak nucleus of Italians last December. A fine Carniolan queen was sent in, and she was introduced to this nucleus of Italians. They began breeding almost immediately; and this spring, when we took them out, there was the original lot of Italians and a fair-sized colony of Carniolans of all ages. About four-fifths of them were of the black race, and a nicer lot of bees we never saw.

Another thing that developed was that those colonies that were bred so early began to use up their stores. They were given pie-plates of candy, as already explained, and the breeding continued. More anon.

THAT SCHEME FOR BRANDING QUEENS.

IN this issue Mr. H. Bartlett-Miller tells of a scheme for branding queens—that is to say, painting them with a brush so that they may be instantly recognized on the frames among other bees. The scheme looks like a good one, and it will be especially valuable where black bees or dark hybrids are used. Where bees are put “on the run,” the queen is pretty sure to join in the general “skedaddle,” making it almost impossible to find her. A little dab of color on her back and wings would help out very materially. With ordinary medium-strength colonies of Italians, Caucasians, or Carniolans it seems to us that it would hardly be necessary to go to the trouble of branding the queen. In the case of bees of quiet behavior it is not difficult to find the queen-mother. The ordinary practiced eye will catch her almost as soon as she comes in sight.

According to our correspondent it takes considerable time and skill to do this branding. The time consumed in doing this work in the first place apparently would about equal the extra time that might be required to find the queen without the colored markings; so we should say it is about an even stand off, with the advantage in favor of no branding. While Mr. Bartlett-Miller reports the marking with color seems to have no bad effect, yet we should be very much afraid that, in the case of valuable queens, the bees later on might ball them. And is it not true that the color would wear off in the case of a good layer?

OUR SYMPOSIUM ON EXTRACTING.

WE take pleasure in presenting in this number our symposium on the subject of extracting, in both a large and a small way; in fact, covering the whole field from the standpoint of the latest developments. It will be noticed that each of our correspondents works in a slightly different way from the others. There are some who prefer small hand machines, and others who recommend and use the large power outfits, either centrally located or portable. Mr. R. F. Holtermann has the largest extractor in the world. Of course we have not forgotten the 24-frame non-reversible machine made for Mr. Osborn, of Cuba, some twelve or fifteen years ago. But apparently this was too much of a good thing. The machine used by Mr. Holtermann is as large as is practicable to make a machine.

The advantage of a large machine over a small one is that the combs can be kept re-

volving for a longer period of time. The longer the frames can be kept on a whirl, the dryer they will become. Small machines, unless the combs are kept in them for the same length of time, would make the process of taking a given amount of extracted honey too slow. Combs that are very wet contain too much honey to go back into the hives. Some large producers believe that the residue of honey sticking to the combs just extracted is not *all* put back in the combs, but that much of it is simply wasted by the bees eating more than they require, just as their owners sometimes do on Christmas and holidays.

There was a time when many large producers seemed to prefer one large central power extracting station, and carrying the combs to and from the outyards. Apparently they are beginning to find that it is more economical to carry the extracting outfit than the combs. There are still others who have a small machine and a complete outfit at *each outyard*. But Mr. R. F. Holtermann appears to be one of the large producers who carries a big power outfit with him from yard to yard, and he has made a success of it. While a 12-frame machine is more difficult to move, yet with the right kind of planning it can be used at all the outyards together with the requisite equipments. Mr. Holtermann's article deserves careful reading, as he is working out a new proposition—that is, whether a large 12-frame power-driven outfit is more efficient carried from yard to yard than two eight-frame machines driven by one engine. This is a big question. Human labor is the most expensive factor that the beekeeper has to deal with. The larger the capacity of the outfit relatively, the less the cost of removing the honey from the combs, providing, of course, a plan has been carefully worked out, so that there will be no false motions and no waste of time on the part of several men waiting on *one man*. The secret of managing help is to plan the work so that all the men will be busy—so that each one on arrival at the yard will know just what his duty is, and a good boss will see that every man makes every minute count.

There are several other equally good articles in this number that will bear careful reading; for we believe that we never published any issue of GLEANINGS that has had more real trade secrets in it than are given in this symposium. The big men have been big enough to tell their fellow-competitors their own tricks of the trade. Of course none of them will ever lose by it, and each will be the gainer.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

THAT tramp beekeeper spreading bee-disease, p. 138, suggests the thought that it would be some help in such a case if there were some way by which a man would have to buy the right to territory before he could dump sick bees upon it.

R. F. HOLTERMANN, p. 123, you enumerate the advantages of the $\frac{5}{8}$ top-bar over one $\frac{7}{8}$ thick. That's all right for extracting; but the beginner should be told that these advantages are overbalanced by the whiter sections obtained over $\frac{7}{8}$ top-bars. [Many others have testified to the thing mentioned by Dr. Miller; namely, that sections are whiter and cleaner over a $\frac{7}{8}$ -inch top-bar than with a $\frac{5}{8}$ or $\frac{3}{4}$.

BEGINNERS who start out-apiaries with their automobiles will never know the thrills we older ones had with our horses. But they were thrills of fright and fear. The worst scrapes I ever had with bees were in connection with horses, and I always drew a long breath when well started away from an out-apiary. I never had any very bad accident, but some narrow escapes, and there was always that dread which helps to turn one's hair white.

L. C. BOUSSEAU sends design for self-spacing. Sole leather $\frac{1}{4}$ inch thick, sliced nearly through in $\frac{1}{4}$ -inch squares, to be cut entirely apart after center holes are punched. Ought to be good if bees don't gnaw them. [Dr. Miller forwarded to us specimens of the sole-leather spacers. Even if such leather were sliced so as to be $\frac{1}{4}$ inch thick it might swell out or dry up. If the latter, it might shrink down to one eighth. This would render it useless.—Ed.]

J. L. BYER, p. 141, I feel a bit shaky about insisting that 32 to 35 would be an ideal temperature in a four or five months' winter confinement of bees. I'd give something to know what it is. Please say what temperature you would prefer without any change for a five-months' pull. But I've some question whether 32 to 35 would start brood-rearing as soon as a much lower temperature. You know brood-rearing starts earlier outdoors than it does in cellar; and isn't that because it is so much colder outdoors?

E. D. TOWNSEND says of foul brood, *Review*, 45, "Once in a locality, always in that locality. One can free a hive of the disease, very probably a yard, but not a locality of any considerable area." I guess that's about right, Bro. Townsend, at least regarding the European brand. [This state-

ment of Mr. Townsend is generally true, but not always so. We have apiaries where foul brood formerly existed, but they have been free from the disease for many years. But if foul brood once gets into a set of combs it will keep cropping out from year to year in the apiary where they are used; and then the only thing to do is to melt *all* the combs and start anew on fresh foundation. That is precisely what we had to do in the yards that originally had foul brood. We have never had European foul brood in our yards, and therefore can not speak from experience.—Ed.]

APROPPOS of J. M. Munro's letter about bees changing color, p. 129, J. Kruse, *Centralblatt*, 343, gives a circumstantial account of several cases of changing to darker color, and *vice versa*, caused by change of location and pasturage. Buckwheat and heather darken the color. This change occurred during the life of the same queen, and there was also a change in the character of the bees! [We arise to inquire if this is true. Does the color of the honey affect the color of the bees? We are frank to say that it does look reasonable. We admit that the kind of honey sometimes affects the temper of the bees, or rather, we should say, the manner in which the honey is secreted from the nectaries of the flowers. A plant like buckwheat that secretes honey only during the early hours, and then stops, will make bees crosser than the white clover that secretes honey all day.—Ed.]

DR. ZANDER says that at 68 degrees Fahr. a man requires 3 1-3 times as much air as a lot of frogs weighing as much as the man, and a bunch of bees of the same weight requires 74 times as much air as the man! Commenting on this, Franz Richter figures that at 68 degrees a colony weighing 13 pounds requires hourly the enormous quantity of half a cubic meter of air, or 17.6 cubic feet!—*Bienenvater*, 61. I thought I had a pretty high conception of the importance of air for bees, but I'll have to run it up another peg. [You seem to think a cubic half meter of air is a large quantity. To us it seems rather small. A good deal will depend, however, on whether the bees are in a semi-quiet condition in the cellar or outdoors. In the former place they would not require, at a mere guess, more than a fourth the air that they would when they are active in summer.

We are quite prepared to believe that a man would require three times as much air as a lot of frogs weighing the same.—Ed.]

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

It is to be hoped that the ruling relative to shipping beeswax in boxes instead of bags will never be in force in this country, as it would be a lot of bother for nothing. I have shipped many hundreds of pounds of wax in bags, and never once had the first complaint. But I always double the sacks, and take no chances. Being able to buy large sacks at about 3 cts. each, the package is very cheap, and always handy to use. It seems a pity that the carelessness of a few will often make trouble for a great many other people as well as themselves.

* * *

HOW BEES ARE WINTERING.

We are getting all our "winter" at the tail end of the season here in Ontario. We had a mild January; but February and March, to date (7th), has been steadily cold with high winds. There has been no snow here in York Co. to speak of; but north 100 miles at the Lovering yard it is mountain-high. Hives have been exposed all winter to the cold; and often have we wished for snow to shelter them somewhat. Reports received during the past two weeks are not as good as early in February, and present prospects point to heavy losses outdoors wherever bees were not fed well last fall. Natural stores do not seem to be of good quality, and much granulation is reported.

* * *

In reviewing Mr. Sladen's splendid work on the bumblebee, p. 73, the editor says that "the sting of the bumblebee is not very severe." I don't know about that. It all depends on the size of the *bee* doing the stinging and the size of the *fellow* getting stung. My earliest recollection of bumblebees is of having been told by a chap older than myself that "queen bumblebees can not sting." Shortly after getting this bit of knowledge in my cranium, I sauntered out into a patch of sunflowers where numerous members of the bumblebee family were disporting themselves; and after a careful look a "queen" was found on one of the blossoms. I was only five years old at the time; and whether that has any thing to do with my recollection of the affair or not in so far as the size of the *bee* is concerned I am not prepared to say. Any way, my memory says that this particular "queen" was about an inch long; and when I confidently grasped her in my hand the sting I received felt much longer than an inch, and the small drop of blood that oozed from the puncture

gave me such a scare that the pain, coupled with the sight of blood, made me exceedingly emotional for the time being. Since then I have learned that, while the queen can sting, the drones—at least those of some species—can not do so. Especially is this so of the chaps that are often found under trees on hot days; and in schoolday times we used to call them "shade bees," and catch the poor fellows with impunity.

* * *

Mr. Pettit's footnote to my article on page 113, Feb. 15, requires some slight explanation. In the first place, I cheerfully admit that I am to blame for not being more careful in writing copy for the bee journals, as I never rewrite any thing. That explains why I am made to say, "during the past season," when I certainly meant to say, "during the past few seasons." Aside from that I have no apologies to make, as I have simply stated facts as given to me. What my own opinion is, that is another matter; but Mr. Pettit knows, or should know, my attitude, as *actions* speak louder than words. I have nothing but the best wishes toward all educational movements, let it be in beekeeping or any thing else; but I do not think it is wise to publish in the daily press reports of big honey yields and profits, when often gross returns are given instead of net receipts.

As to doing "government work," there are other methods of getting information aside from being on the civil service; and as to the term "producers," all will understand that I had in view the people who mainly depend upon beekeeping for a living.

By the term "boom" I rather had in mind the great activity in the bee business, the attendant high prices of bees, etc., instead of the high price of honey as Mr. Pettit seems to think was the case. And yet I am not at all dissatisfied with the advance made in honey during the past few years; for although honey has not increased as much as some food products, yet no one will dispute that the raise has been substantial. Only seven years ago, if I remember correctly, I sold my first large amount of honey at 7¼ cts. delivered, and was very glad to get that price. This year I sold very readily honey no better, at fully a half more than that figure. Honey is not too high in price—many honestly think it is not high enough; but, all the same, I am very thankful that prices are as good as they are—things might be worse.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

Thousands of colonies have been shipped to the alfalfa fields of Nevada, Utah, and Idaho during the past two years, and others are still going. A good old-fashioned honey crop in California would have a strong influence in checking shipments.

* * *

The good rains of which I spoke in the last issue stopped abruptly, and we are again anxious for weeping skies, for our season for rains is growing shorter day by day, with yet far too small a rainfall to hold the honey-plants through the blooming period. The sage that escaped the frost is doing finely, and has an exceptionally healthy color and growth. The oranges will be blooming in a short time in profusion; so if we get plenty of rain to aid the sage, who knows but we may yet die rich?

* * *

The California State Beekeepers' Association will, in the future, be known as the Consolidated Honey-producers of California. When our foul-brood law was introduced in the State legislature, one of the features of the bill was that it placed the appointment of the inspectors largely in the hands of the association. The law-makers, upon investigation, found that there was no legal organization on record known as the California State Beekeepers' Association. The situation was grasped quickly by the officers of the association, and a meeting called to organize under the laws of the State to give a legal standing as well as a legal name. There had previously been an organization known as the California State Beekeepers' Association which was officially dead, but the name could not be used again in an official way, so the name stated above was chosen.

* * *

I recently had the pleasure of entertaining Mr. C. C. Matthews, of Idaho, and Mr. M. H. Mendleson, of Ventura. Mr. Matthews is in California buying bees to ship to Idaho. He is a beekeeper with much experience, and will doubtless succeed. Mr. Mendleson needs no introduction from me; but I must say I have rarely enjoyed a visit from any one more than this one. With so many years of experience among the bees, and such a large producer, he is a landmark in California beeedom. I also had the pleasure of signing a petition for a son of Mr. M. Seager, who is out for the office of County Inspector, and has the solid backing of our county association. The elder Mr.

Seager is a beekeeper of long experience, having been in the bee business in California for the past 37 years, and a good friend of the writer.

* * *

Utah is now wrestling with a foul-brood law that makes inspection at the State line necessary on all shipments of bees entering the State. We in California are now trying to get a law to overcome the evils of county ordinances of an uncertain nature, and make it possible for the clean and careful beekeeper to transport his bees from one part of the State to another, and make it impossible for an inspector such as we have had in San Bernardino County to hold the office for ten years over the protest of the beekeepers. I believe with Editor Root (p. 139, March 1) that a federal law should be enacted at once; not only, as he says, to stop the unprincipled tramp beekeeper from spreading disease, but to have a condition of certainty in law that will give clean bees a clean bill of health for shipment from one State to another, avoiding the necessity of State quarantine laws that seek to correct an evil and make a worse one.

* * *

Iowa State convention recommended the amendment of their present foul-brood law to prevent the shipment of bees into that State. I thought California had all of the insane notions there were on this subject; but here comes Iowa with a notion as bad as any we can produce. It is to be hoped our legislators will not allow the beekeepers to persuade them to repeal the inter-state commerce law without giving the national Congress at least due notice of their intentions. I doubt very much if the ruling of our California Agricultural Commission would prevent the shipment of bees from Utah to this State, if a test case were made in the United States Courts, unless it could be shown that the bees or fixtures actually contained evidence that the alfalfa weevil was being transported to this State. I do not believe any court would hold that the mere fact that there was danger of the weevil being brought in would be sufficient to stop a shipment of bees, or any thing else for that matter. There are few ships, of the many that land at our harbors daily, from which there is not danger of disease being contracted; yet the ships come and go, being subject to quarantine regulations, to be sure, but not prohibited from landing if no contagion develops within a reasonable time.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

SWEET AND SOUR SOIL.

Acid soil is sour, and will not grow clovers well. Acid soil will turn litmus paper from blue to red. If you have an acid mouth your breath will do the same to the blue litmus paper. If you have an acid mouth you will soon be going to the dentist unless you sweeten your mouth out with a toothbrush and tooth-powder. A clean tooth never decays. Lime sweetens the soil and allows the clovers to grow. And what could be more natural than for a sweet soil to grow plants that will produce abundant nectar? Emerson said there are many sweets in the soil if we but knew how to come at them. He did not tell us, but we now know how to come at them by liming the soil and planting the clovers. The bees will collect the sweets for us. A land flowing with milk and honey will be found where limestone sticks out of the hillsides. The clovers grow, the cattle fatten, milk is abundant, the locusts thrive on the clover, and the wild bees collect the wild nectar for the diet of any John the Baptist who cares for a diet of locusts and wild honey.

* * *

GLASS SUPER COVERS.

On page 52, Jan. 15, you spoke of Mr. Babberger using panes of glass for honey-boards. Will you be so kind as to give me a little information on the subject? I also use the Danzenbaker hive. Does he use panes of glass 16 x 20 the same size as the hive? and does he use single or double strength glass? Is it not likely to get broken in prying it up, being stuck with propolis? Does he let it stay on there all the year? Does he use a super cover of wood in connection with it?

North Carolina.

S. D. M.

Mr. Babberger uses glass 16 x 20, or very close to that. They are the size of the outside of the hive. He uses single-strength glass, and says he has but little trouble with breakage. I believe he told me that he broke, on the average, two glasses each season.

Mr. Babberger says that bees should not be molested when the propolis sticks. I should judge from his remarks that he does not open his hives except in warm weather. He tells me that he can give his bees a very fair examination without removing the glass. The glass is used as a honey-board over the supers in summer, and nothing but the cover is used with it.

* * *

WEIGHT OF HONEY IN 4 x 5 SECTIONS.

You speak of Mr. Hill and Mr. Babberger using 4 x 5 plain sections. How do these men get the 4 x 5 x 1 1/2 sections to come under your "fancy" and No. 1 grades? As I understand it, these grades must weigh 13 1/2 oz. I am using the 4 x 5 x 1 1/8 sections,

and can't get the very best of them to go over 13 oz. Do these men use 4 x 5 x 1 1/8 or the 4 x 5 x 1 1/2? I am thinking of changing to the 1 1/2. What will the 4 x 5 x 1 1/2 weigh when well filled? I want a plain section that will weigh a pound when well filled. Will the 4 x 5 x 1 1/2 do this?

Missouri.

T. H. B.

Neither Mr. Hill nor Mr. Babberger grades honey according to the Colorado rules. The Colorado rules are made for the 4 1/4 x 4 1/4 x 1 7/8-inch section. But I do not understand why you can not get heavier honey than an average of 11 1/2 to 12 oz. in 4 x 5 x 1 3/8 sections. This is the size used by Mr. Babberger, and I think Mr. Hill's are the same, although I am not certain.

Leaving the bees a bee-space on each side of the beeway section, and allowing for the bee-space provided by the fence separator used in the Danzenbaker super, I find that the 4 x 5 x 1 3/8 section has 27.5 cubic inches of available space for the building of comb, while the 4 1/4 x 4 1/4 x 1 7/8-inch section has only 27.09—a difference in favor of the tall section of about two-fifths of a cubic inch. I am satisfied that Mr. Hill has many sections weighing from 13 to 15 ounces. Several years ago I produced quite a little honey in 4 1/4 x 4 1/4 x 1 1/2 plain sections, using fences, and had little trouble in getting them to weigh 13 to 14 ounces, though I could not get the bees to put a pound in them.

Do you put in full starters, filling the box full with a top and bottom starter? Perhaps you had an unfavorable flow this last season; or you may put on too many supers, and make the bees slight their work.

I have had no experience with the 4x5x1 1/2 section; but I know some Colorado beekeepers who have used 4 x 5 x 1 5/8, and they get comb honey averaging a pound, and some sections will weigh more than that. I doubt whether you can get the average comb built in a 4 x 5 x 1 1/2 to weigh a pound.

Why do you not use a standard section? By removing the super-follower, using separators between each row of sections, having a top starter of two to three inches, and a bottom starter of 5/8 inch, you can get combs to weigh one pound each. But that space left when the follower is removed must be equalized as nearly as possible between all the rows of sections. The way one Colorado beekeeper (Walter Martin) does is to shake the super from side to side lightly, thus leaving the spacing about right. When the bees have begun work, any uneven spacing may be adjusted, and then the bees will soon glue it so that it will stay.

Conversations with Doolittle

At Borodino, New York.

BEES AS ESCORTS FOR QUEENS IN MAILING.

I expect to rear queens for sale this coming season. Please tell us how many bees to put in with any queen as escorts. What should be their age?

In mailing queens it is important to use the right number of bees of the proper age. During the summer months, and where the queens are to go no further than the domains of the United States or Canada, this ordinary small mailing-cage answers very well, and the proper number of bees to use is from eight to twelve, according to the temperature which is likely to be met while they are in the mail. For very hot weather, and with the destination to be in the middle and southern States, I have found that eight bees do best during the last half of June and the months of July and August, while for the northern part of the United States and Canada I generally use ten for July and August, and twelve for the other parts of the mailing season.

Some years ago I went through a series of experiments to ascertain these things, some of which covered a period of nearly four months. I prepared and provisioned the cages in different ways, and used different numbers of bees, using queens which I wished to supersede, not on account of their age, but on account of their being mismated. Being thus prepared, the same as were others which were mailed, these were put in a dark place in my shop, some in the lower story, others in the upper story, where it was very warm the most of the time; and three or four times during each week these cages were either thrown about the room or left in an old sack made of leather, and the sack tossed about, something after the manner in which I had seen the mails thrown off fast-running trains. Without specifying further as to details, in this way I arrived at what I considered the different ways best suited for a successful termination; and although I have tried nearly all of the devices brought before the public since then, few, if any, have proved better than what I settled on then.

But for either spring or fall I do not believe that the best results can be obtained by using these small cages. For these reasons, and for all places outside of the United States and Canada, a larger cage should be used, one having at least twice the capacity. With this larger capacity I use from twelve to twenty bees in accord with the expected temperature and the distance to be traveled. Then for all places outside of North America, a still larger and differently constructed cage should be used, one

which will allow the bees to collect in a comparatively closed apartment when passing through a low temperature; but that where extreme heat is encountered, will allow them to have access to a larger and well-ventilated compartment. With cages constructed after this fashion, and with from twenty to thirty bees, I succeeded in getting three out of five queens alive and in good shape clear to Western Australia, this requiring a period of thirty-nine days.

As to the age of the bees which are to accompany queens while in transit, the younger the bees are which have had a cleansing flight the better. Young bees which have never flown to void the pollen excrement which accumulates in their intestines through their larval and pupa state, are liable to soil themselves, the queen, the food, and the cages, where more than two or three days' time must be consumed during any journey through the mails. And old worn-out bees are little if any better.

Just how to tell which are the old and which are the young bees is a matter that often puzzles very many. I studied many a long week, month, and even years, in this matter, and I conducted different experiments along this line, till finally, in watching the bees carefully, after only just enough smoke had been used to quiet them properly, I found that, as a rule, bees which were from six to ten days old, the same being slim in appearance, were the ones which would stick their heads in the cells of honey surrounding the brood, and begin to fill with this honey. And such are the bees which I have used for nearly thirty years, with good success. And, what is in our favor, is that, when in this position, these bees are the most easily picked from the combs, as the wings stand out inviting us to take hold of them, and thereby carry them to the cage in the manner best suited for their entering the cage, and with an almost positive insurance against being stung.

Some queen-breeders say that we should never put in a bee that has stung us, as it will soon die, and is quite likely to get stuck fast in the entrance to the food-chamber. I used to think so myself; but finding that it was not the easiest job to get a bee out again which had left its sting in my finger when closing the entrance to the cage, I wrote to a party in Texas, to which such a cage was going, to inform me on arrival if there were any dead bees in the cage. In due time he replied that every bee was alive, and "smart as a cricket."

LABOR-SAVING PLANS IN LARGE OUT-APIARIES

Different Problems in Different Localities

BY R. M. SPENCER

Locality has much to do with the methods of handling bees, either on a large or small scale. Where I am located the winter problem is nothing compared with that of cold climates. Here a nucleus of three frames of brood and bees will winter in good shape provided they have plenty of honey for stores. In the East the main problem in spring is to get the bees to build up in time for the flow; while here the main problem is not to let them build up too fast and swarm before the flow starts.

In this locality bees begin to breed about Jan. 15, and have a light honey-flow until about May 15, when the main flow starts. It is easy to see then that the breeding season is very long. This compels us to use a large hive. Ten frames is what I use, and tier them up three stories high, allowing the queen to breed in all three bodies if she desires. This long breeding season makes a race of bees such as Italians more suitable than any swarming races like Carniolans.

Our work here generally begins about Jan. 1, when we go to all the yards, close the entrances down to about two inches, and take up all dead colonies to prevent the combs becoming moth-eaten. About Feb. 20 we go over all hives, remove supers and surplus honey, stacking the same up in the yard. During March we build up the weaker colonies by taking brood from the stronger ones.

WORKING SO RAPIDLY THAT ROBBERS CAN NOT KEEP UP.

We use a method of preventing robbing during this early spring work by going over the hives so fast that robbers can not get a chance. Each man has his duty to do. Say a crew of five men were going through a yard of 250 colonies in a day. The first man's duty is to take off the lids. No. 2 smokes the bees. No. 3 glances into the hive, calls out the number of frames of brood; or, if a frame is wanted, he calls for it. No. 4 brings the frame and puts it in a vacant space and returns the empty comb to a box of combs which is always kept covered. No. 5 then replaces the cover and sees that it is secure from robbers.

By this method we go over the hives so fast that robbers do not stand a show. We sometimes see them trying to get under the lids, five hives or more behind where we are

working. If they become bad we paint the cracks with fresh white paint, and they will not try to get in, as the bees will not alight on fresh paint. We also jump over to the other side of a yard after getting over one row, and this also throws them off their track.

We always aim to keep not too many bees in a yard, but yards close together. We figure that, if we have 2000 colonies in four yards of 500 each, in case of disease we have to fight it in 500 colonies, while if we have eight yards of 250 each we have only 250 to look after. Again, in poor years 500 will not make a living, but 250 will. On the other hand, large yards cost less to operate, and produce large crops in good years. We try to locate all our yards in well-sheltered places away from winds.

There is no question in my mind but that in many cases queens have been condemned for poor qualities when the main cause was drifting of bees. In a large yard of several hundred colonies, those in the center of the yard will always be in poor condition while the outside colonies will be strong. I have often noticed this in my yards where the flow in spring began on oranges to the west. The west side of these yards would be very strong, while later on, when the flow from other sources began in the east, the colonies on the east side would build up quickly, while those on the west would become weaker. The way to prevent this is to keep the hives in groups, or by some well-marked location. About all the locations in California are now occupied except some that are back in the mountains where roads must be built in order to reach them. Many localities are already becoming overcrowded.

One of the main problems here is to secure labor to handle the bees. It is hard to get help who will go back into these canyons and live and handle the bees.

All our hives are three-story, and all the honey is sealed and thoroughly ripened before extracting. We use the usual methods of extracting, running the honey into tanks in order to clarify it.

GALVANIZED TUBS FOR UNCAPPING-CANS.

We find the best uncapping-boxes for our use to be tubs with a one-inch opening at one side on the bottom. These are set over a trough, and the honey is allowed to drip into the trough and run into tanks. The advantage of these tubs is that we can use one to-day and let it drip clean until to-morrow, when we screw in the plug and haul the whole thing home, and melt the

cappings there. All we need is a large supply of tubs to handle the cappings as fast as filled.

Nordhoff, Cal.

SPRAYING FRUIT-TREES IN BLOOM

Advice in "Better Fruit" in Regard to it

BY J. A. GREEN

One of the most subtle attacks on bee-keeping interests that has ever come to my notice is contained in articles in *Better Fruit*, a magazine published at Hood River, Oregon. *Better Fruit* is a high-class magazine, well printed, superbly illustrated, and occupies a very high place among publications devoted to the fruit industry. In the January number are several articles by W. H. Volek, Horticultural Commissioner of Santa Cruz County, California, who is listed as one of the associate editors. In one of these, after reciting the damage done in his district by various leaf and fruit eating insects which begin their work very early, he says, "These foliage and flower-devouring insects are all controllable with arsenicals provided the spraying is properly done in due time. Owing to the very early attacks of tussock caterpillars, canker-worms, and leaf-folders, the first spraying should not be delayed until the blossoms have all fallen, but applied while the trees are in bloom. The period from full bloom to the time when two-thirds of the blossoms have fallen appears to be the most practical timing. Spraying with good arsenicals will cause no injury to the blossoms." Later, in the same article he says, "Apply the first spraying when the trees are in bloom, full bloom to the time when two-thirds of the blossoms have fallen."

In another article, speaking of a special brand of arsenate of lead, he says, "It may also be used on apples and pears in the Coast districts if applied very early (while the trees are in bloom), or if combined." Again, "Acid arsenate of lead may be used . . . if applied before the trees have gone out of bloom; but any later sprayings will be dangerous." Once more, "The first application for canker-worms, codling moth, etc., had best be applied before all the blossoms have fallen;" and, finally, "In the Coast districts the earliest application (before all the blossoms have fallen) may be made."

The persistent reiteration of the same idea shows a deliberate purpose to induce as many as possible to follow his teaching, though he cleverly avoids giving any reason for it, further than that the leaf and bud

eating worms that he mentions begin their attacks very early, before the blossoms are open. The position of the man, and his evident familiarity with all the minutiae of spraying, will tend to lead many to follow his advice without analyzing it or suspecting any ulterior motive.

Now the facts are that, for the purpose of poisoning the tussock caterpillar, canker-worm, or any other of the leaf or bud eating insects that begin their work early in the season, there could be no possible advantage in having the tree in bloom when the spraying is done. A spray applied four or five days earlier, before the blossoms open, would be even more effective in controlling them, if time is any object. But unless these pests were unusually bad, there could be no great harm in waiting four or five days later, until the petals of the blossoms have dropped, which is the proper time to spray for the codling moth. For the control of the codling moth, a more effective job of spraying can be done after the petals have dropped and the stamens have withered and separated, so that the calyx cup can be more easily filled with poison. Also this spray will be equally effective in controlling the later attacks of all leaf, bud, or fruit eating insects.

The statement that spraying will cause no injury to the blossoms does not agree with the experience of many practical orchardists, nor with the teachings of nearly all the authorities. Most spraying is done nowadays with power-sprayers; and to do effective work a pressure of 200 lbs. should be maintained. I have seen even leaves and apples torn from the trees by such a spray, and it is only reasonable to suppose that, when it is driven upon the delicate organs of the blossoms, it will more or less damage them and prevent the proper performance of their functions, aside from the corrosive action of the spray or the hindrance to pollenization by the thorough wetting.

I have written to the publishers of *Better Fruit*, and hope that something may be done to counteract the influence of these articles. I shall write to several others of the associate editors, with whom I am acquainted, to enlist their influence if possible against this revival of an error that had nearly died out among fruit-growers, or at least the better-informed ones. Bee-keepers should post themselves on the principles that govern spraying, so that they may be better prepared to overcome the evils that the ignorance or prejudices of fruit-growers may bring upon them.

Grand Junction, Colo.

[We sincerely hope that our correspondent's efforts may succeed, for it is to be regretted that a horticultural magazine should come out with such a statement right in the face of conclusive evidence to the contrary that is being sent out by so many of our experiment stations. Here is another communication along the same line.—Ed.]

SPRAYING TREES IN BLOOM

BY H. F. WILSON

Assistant Entomologist, Oregon Agricultural College, Corvallis, Oregon.

Mr. W. H. Volek, Horticultural Commissioner, Santa Cruz County, Watsonville, California, in the January number of *Better Fruit*, under the heading of "Caterpillars, Codling Moth, Aphids," pages 16 and 17, makes the following statements: (Quoted above.—Ed.)

Note that he states that the time mentioned *appears* to be the best. This recommendation, which is undoubtedly given on reliable data and experiments, is a very dangerous one for both the beekeeper and the horticulturist. Certainly such a practice can not help causing the destruction of insects which feed upon the nectar of the blossoms, and, climbing about over them in search of it, aid in cross-pollination. In localities where it is followed, the honeybees will be destroyed; and one of our local beekeepers suffered such loss from the spraying of a single orchard that he was compelled to move to an entirely different locality.

It is a common recommendation of this station to suggest bees for the orchard and farm, both for the value received from the cross-fertilization of fruits and the surplus honey secured.

In view of this recommendation I will state that in Oregon we have the tussock moth, canker-worm, and several caterpillars which cause more or less damage to the fruit; but in only one instance have they caused enough damage to make it necessary to consider methods of control other than those now in use.

In localities where it becomes necessary to combat these early-feeding caterpillars, the spray should be applied before the blossom-buds open. At that time the young caterpillars will be feeding, and should be more easily destroyed than a week or ten days later.

There may be some opposition to this extra application on account of the cost; but surely the value of the cross-fertilized fruit over the self-fertilized will be more than the cost of spraying.

Just how much we can depend upon the wind and air currents for distributing pollen is hard to say; but several investigators have carried on experiments which tend to show that not as much pollen is distributed in this way as one would expect.

In conclusion I would suggest that the fruit-growers of every State be careful about spraying when the trees are in bloom; and such a practice should be resorted to only as the last and final means of insuring a crop of perfect apples.

A COLLAPSIBLE EXTRACTING-HOUSE AT EACH YARD

Hauling Combs Home to Extract Keeps the Bees Confined to One Story too Long

BY LEON C. WHEELER

Personally I should not like the plan of working outyards and carrying the combs, etc., back and forth every trip. I find that, if not absolutely necessary, a honey-house at each yard is at least extremely handy; and when one can have good portable houses at a cost of \$25.00 to \$40.00 each I believe that they are an economy. It is almost impossible to estimate accurately the amount of combs one will need at an outyard; but he can very easily have a supply of them in the honey-house at the yard, and can draw on them at will.

A light spring wagon will take the extractor, capping-melter, gravity separator, etc., to the yard, and a few cream-cans make excellent receptacles for carrying back the honey. If one has a permanent stand arranged at each honey-house it is a short job to set up the extractor and begin operations. Many of these combs must be put right back on the hive, and a lot of time is saved by not having to take them home and then back again another day. Then, too, the combs are on the hive quicker, and, consequently, the bees are not left so long in the cramped quarters of the single hive-body.

Large full combs of honey are not the easiest thing in the world to haul over rough country roads without breaking them; and as the most of this work comes at the close of the clover flow, and before the beginning of the buckwheat flow, bees are inclined to rob; and each hive, as one loads it, has to be carefully covered; and still, in spite of all one's care, he finds before he gets through loading that there is a swarm of eager excited bees around the load. These bees may not do any harm to the man who is fortunate enough to own an auto; but we poor fellows who are compelled to drive

a horse don't enjoy hitching up in a swarm of bees.

I'd much rather have that honey all extracted and put up in good tight tin cans; for then when I get through I can throw it on the wagon, hitch up without any bees to molest me, and hike for home as fast as the horse cares to go—no trouble about breaking combs.

Then, too, when I am working among the bees before extracting time I often find it to my advantage to take out certain combs of honey from a hive, and it is very handy to have an extracting-house in which to store these.

In loading the extractor on the wagon I set it flat on the bottom of the wagon, and fasten it there with two or three screws, and the pockets are tied to keep them from rattling; and when it is fixed this way there is no trouble about driving as fast as you want to. My extracting-house is built in six pieces—two sides, two ends, one floor, and one roof piece. These are bolted together at the yard, and strips nailed on over the corners to cover up the cracks which might otherwise let in some bees where the building is joined together. There is just one window which faces the yard; and this is fitted with escapes. There are two doors, one entering the yard and the other facing out, which admits of driving a team on the opposite side of the house from the bees to load. These doors are both fitted with foot latches—a very handy device which allows one to open the door with the foot instead of having to set down the hive, or whatever he is carrying, in order to open it. I should consider it a useless expense to fit out each yard with extractors, etc., as they can be easily carried along.

Barryton, Mich.

THE JEFFERSON AND ST. LAWRENCE COUNTY CONVENTION

BY R. F. HOLTERMANN

The two-days' convention held at Ogdensburg, N. Y., Feb. 20 and 21 did not lack in enthusiasm, and there were a goodly number of extensive beekeepers present. I shall make no attempt to report the convention generally, but simply record a few points which impressed me.

F. C. Hutchins, Massena Springs, upon the subject of "The Management of Outapiaries," said that his home apiary consists of 300 colonies, which he looks after himself, getting the help of two or three boys in extracting time. His experience is that if bees winter well they will spring

well. He wants good queens, not more than two years old. On account of European foul brood he gives Italians the preference, although so far he has found no disease among his bees.

Mr. Hutchins advocated equalizing colonies by changing hives, putting strong colonies in the place of weak ones, and weak in the place of strong when honey is coming in and the bees are flying. He has also built up weak colonies by placing them over strong ones with a wire cloth between the two colonies. He has had some swarms when producing extracted honey, but not many. Swarming is kept down by means of shade, large entrances, and plenty of room. Where there are 200 or 300 colonies in an apiary he recommends that some one be placed in charge all the time. They can have any swarms that issue, and enough work can be found to keep the attendant out of mischief. Mr. Hutchins also recommends a complete extracting and other necessary outfit for each apiary. He feels sure a good honey crop can be secured in an apiary with several hundred colonies if the bees are strong at the beginning of the honey-flow.

The question of breaking down queen-cells to prevent swarming came up. I stated that, when breaking down queen-cells that are the result of the swarming impulse, I make a point of removing all the royal jelly, reasoning that, if any of it is left, there will be a greater chance of the bees starting some more cells with the intention of swarming later. I do not shake a colony simply because it builds cells for swarming, for often the swarming impulse does not continue when the cells are broken down. Sometimes, however, it does continue, and I find instances where it would have been wiser to shake the bees instead of thwarting them week after week. However, on the whole I have gained more than I have lost by delaying or not adopting the "shake system."

Mr. T. Davis, Ogdensburg, gave a method which he had adopted, of destroying capped cells—a method which Geo. B. Howe, Black River, had also practiced for many years. This method consists in tearing the capped cells open at the side and destroying the embryo queen. If the cells are destroyed in this way the bees think their own queen destroyed them, and they destroy any cells the beekeeper might miss in the hive. Bees do not destroy the remaining cells unless the cells found are destroyed as described. Mr. Howe stated he had been following this plan for fourteen years with entire success.

Brantford, Canada.

To be continued.

Woodward's auto truck loaded with 105 supers and combs, ready for a trip to one of the outyards.

AUTO TRUCK FOR MIGRATORY BEEKEEPING

D. L. WOODWARD

Last season was my first experience with an auto, and I have enjoyed it very much, although I have found it quite expensive on account of using pneumatic tires and a high-powered car. My machine is a foreign Fiat, 45 horse power and 130-inch wheel base. Most owners of automobiles claim big mileage for their cars; but all I have ever been able to get out of my car is six miles to the gallon of gasoline. I bought it second-hand, buying just the chassis. After buying it I had a detachable touring body built for it. Then I built a delivery body, also detachable, and a truck platform with stakes, as shown in the picture.

The platform is 70 inches wide, 96 long, and is built of oak and ash, a very strong construction, but heavier than necessary.

Let me say right here to prospective buyers of auto trucks that I do not consider any touring car suitable for a truck. In the first place, it is geared too high; and in the second place the gears are not heavy enough to bear the strain that a truck must stand. I have had the misfortune to strip my differential gears twice during the season, so I know whereof I speak. I do not believe

there is any pleasure-car built with heavier transmission and gears than the Fiat.

I would not advise any one to try to get along without horses in addition to the auto, as there are times when the horses come in very handy, especially in the spring and fall.

For six weeks last spring I was tied up on account of the muddy condition of the roads. If one lives on a State road, that disagreeable feature is done away with. I believe that an auto truck is a great convenience and a great saver of time; but if one can not afford to keep a pair of horses also, I would choose the horses for the heavy work, and keep a light car which would be inexpensive to maintain, for light work, such as marketing honey and running to the outyards.

The ordinary beekeeper would have very little use for a truck unless he practiced migratory beekeeping as I do.

I run two outyards—one five and the other ten miles from my home yard. I take all my honey home to extract, and carry the bees home to winter them. Then about July 20 I move them all on the Helderberg Mountains for buckwheat honey, a distance of ten miles. Last spring my bees were short

FIG. 1.—One of R. F. Holtermann's apiaries of twelve-frame hives.

of stores, and so I moved about half of them six miles from home into a fruit belt for fruit bloom. After fruit bloom I moved them to another location where I could get a large quantity of wild-raspberry honey. In this way they all got enough honey without feeding to carry them through and to keep up brood-rearing.

By means of the auto the moving is done quickly and easily, as I have a full equipment for doing all this kind of work. We usually close up ninety colonies the night before; and the next day, after I haul a load, my man stays at the yard to open the hives, and is generally waiting for me when I return with the next load. I find that it takes me just 45 minutes to cover the twelve miles, including loading and unloading, carrying thirty colonies to the load, fifteen to each floor. I have a skeleton floor that I use in moving bees. It is 18 inches above the platform, and is held up by the stakes. On the rear stakes is a cross-board with notches cut in for the floor boards to fit in.

I also find the auto a great convenience in selling honey at retail, as I live twelve miles from Albany, the nearest market. I have sold in three hours, from my auto on the public market, as much as 103 five-

pound pails of honey besides that which was put up in pint jars and in five, six, and twelve ounce bottles.

It is certainly a pretty sight to see the auto loaded with seven or eight hundred pounds of honey in bottles, and in my special red and gold lithographed pails; and I generally have a good-sized crowd of admirers. I get 12 cents a pound in five-pounds pails; 10 cents for the five and six ounce bottles; 25 cents for the pint jars, and 20 cents for the twelve-ounce bottles. At those prices there is money in bees. Beekeeping is my sole occupation; and from 300 colonies I make a good living and save some besides.

Delmar, N. Y.

THE TWELVE-FRAME POWER EXTRACTOR

BY R. F. HOLTERMANN

Some of my friends claim that I am too conservative. On the other hand, there are those who state that I risk too much; and the reason they give for this statement is that they can point to certain fixtures or implements about the bee-houses which I am not using. These accusations prove to *my*

satisfaction that I am pursuing a fairly moderate course between the two extremes. Be that as it may, it was quite a wrench for me when I decided to leave the hand-turned extractor and venture on what was to me the uncertain sea of a power-extractor outfit.

When I state that, with a six-frame reversible extractor turned by hand, we have been able to extract 8500 lbs. of honey in a day, some will, perhaps, better understand my hesitation. However, after weighing the evidence available, and meditating upon the pros and cons, actual and perhaps imaginary, the plunge was finally made, and the securing of an outfit decided on.

The next thing was to decide upon the size of the machine. An eight-frame extractor was the largest available; and as we had already used a six-frame by hand, this did not seem like difference enough. The manufacturers could give me no help—in fact, their advice rather tended to the purchase of two six-frame machines rather than one twelve-frame. An arrangement was made for a twelve-frame machine, and I ordered a pump attached. I believe I was the first one to order an extractor with a honey-pump attached (now, do not all speak up at once, saying that I was the last).

As to the engine, a few dollars looked to

me pretty serious—a few pounds of added weight, a clog on the whole season's operations; so a $1\frac{3}{4}$ -horse-power engine was decided on. This machine extracted a good crop of honey for the season of 1912; but I decided that there was a slight delay in speeding up the large reel with a capacity of twelve Langstroth frames; and two of these delays with every set of combs made considerable lost time in a day; consequently a $3\frac{1}{2}$ -horse-power engine has been bought to replace the first purchased.

The extractor which I ordered was completed and ready for inspection about July 1, 1911. A visit of inspection was made, and every thing appeared all right. Blocks of wood were placed in the comb-baskets as a substitute for comb. Delay in transit resulted, in that the last day of extracting I received notice that the extractor had arrived at my nearest custom-house station. It was, therefore, too late to test the machine during the season of 1911.

During the winter of 1911 I had 18 galvanized iron tanks built for storing honey. They had tight covers, were 6 feet high and 3 in diameter. Each tank has a capacity of 3000 to 3300 lbs. The best and safest honey-gate I could find was put on them, and a strong stand about 14 inches high was built in each apiary, upon which to set the

FIG. 2.—The twelve-frame extractor, engine, and tanks, loaded on a wagon.

FIG. 3.—Two of Mr. Holtermann's helpers removing honey. One holds the frame, and the other uses a brush in each hand.

tank. My object in having these large tanks was to do away with previous loss of time in changing the filling from one small tank to another or from one barrel to another—to strain the coarsest foreign substances, such as wax, out of the honey, and do the rest of the straining by gravitation, skimming the honey when the separation had taken place. For filling, also, a large tank, where one can fill into smaller packages for a 3000-lb. run, is a gain in time. The pressure is better, and thus the honey may be forced out more rapidly at the open gate. With a barrel, for instance, owing to the pressure from the honey above, the first half of the barrels fills more readily than the second. No strainer that can be utilized can be found that will strain honey at the rate of 1000 to 1500 lbs. per hour, and be fine enough to remove the finer specks of wax, etc. One may not see these specks when the honey is liquid; but when the honey is granulated nice and white, they show at once like dust on the surface, and are very objectionable to the uninitiated, such as the average consumer of honey.

The twelve-frame extractor worked well.

There is no trouble in extracting with it 14,000 to 15,000 lbs. of honey in a day.

Fig. 1 shows one of our apiaries, July, 1912, which produced sufficient honey to fill three of these large tanks and six or seven hundred additional pounds. The hives shown are the twelve-frame Langstroth. We tiered up supers until the close of the white-honey flow, when all was extracted, but not a comb was taken from the brood-chambers. There were brood-chambers so filled with brood (yes, I must confess my lack of foresight) that several colonies actually starved to death for want of food during my absence of several weeks after the honey-flow. (I have no queens to sell. Many beekeepers have as good queens as I have if they would only overcome their prejudices and give their queens a chance in the twelve-frame brood-chamber.)

MOVING.

A question might be asked as to the practicability of moving this extracting-outfit from one apiary to another. In this matter I was most agreeably surprised. Fig. 2 shows the outfit on a wagon. We took the twelve-frame extractor, turned it on its side, and rolled it through the honey-house door, turning it again to its normal position and pushing it up a plank upon the wagon. The engine shown in the same engraving is the small one; but the larger one can be loaded more readily than the extractor. The other implement on the wagon is the uncapping-tank standing by the driver of the horses.

My outfit cost more than I expected; but I am well satisfied with it. It is a great convenience and labor-saver.

Speaking to the young men who spent the season with me learning beekeeping, I said, "If I had been asked at the outset to buy a 3½-horse-power engine with which to extract, I would not now have a power outfit; but by taking two steps the cost was broken to me by degrees, and I yielded."

We found a difficulty in connection with pumping the honey—the belt slipped. A remedy has been found, however, and I have no hesitation in recommending a power outfit for extracting; but I have no use for the plan of hauling home combs of honey to be extracted. The honey can be extracted in the time which it would take to haul the combs to a central station and back again. Also, where there is any danger of foul brood it is much more liable to be spread by changing or carrying combs from apiary to apiary. Of course, if there is no extracting place it is a different matter. If I wanted to keep myself busy without ade-

Honey-house and Bee-cellar of M. C. Silslee, Haskinville, N. Y.

quate returns, the latter system might commend itself to me.

Brantford, Canada.

A CONVENIENT EXTRACTING-HOUSE AND BEE-CELLAR

BY MYRON C. SILSBEE

I am sending you a picture of my bee-cellar and honey-house which was built in the summer and fall of 1911. The building is 24 x 40 feet north and south, having a cellar of the same dimensions. A partition runs through and shuts off the cellar from the tank-room. The cellar is 24 x 30, and the tank-room 24 x 12. I have a room above, 24 x 30 feet, which I use for an extracting and storeroom. I also crate and clean my comb honey for market here. The room is ceiled overhead with matched lumber. I have a power extracting outfit, and pipe through the floor. The pipe is three inches in diameter. It conveys the honey to the tanks in the tank-room below, which hold about 4500 pounds each.

There is a door in the north end of the bee-house, 7 ft. high by 3½ wide, through which I carry the honey in from the hive. The door in the southeast corner of the tank-room is 4 ft. wide, through which I carry my bees into the cellar and then through a door 3½ ft. wide through the partition into the bee-cellar.

Then I have a room in the south end of bee house, 24 x 10, where I have a stove and workbench where I extract wax and nail up hives and supplies. There is a double floor of hard pine with building paper between. I have four trapdoors in the floor, 14 x 21 inches, for ventilating the cellar.

The cellar has a cement floor, and is sealed overhead with matched lumber. The walls under the building are laid up in Portland cement mixed 5 to 1. The walls are 3 feet thick at the bottom and 18 inches at the top. I cover the cellar floor with two or three inches of planer shavings. The bees are set on plank 6 inches from the floor with bottom-boards removed to allow all dead bees to drop out during the winter. I generally put the bees in the cellar from the 10th to the 15th of November, and set them out about April 1. The outside of my bee-house is sheeted with one-inch planed hemlock, shiplap, covered with building paper, then sided over.

The chimney on the bee-house is built of cement. Then I have a building at the northwest corner of the bee-house, which does not show in the picture. It is 12 x 15 feet. I have a gasoline-engine, saws, and dovetail cutter, where I saw my hives and supplies; but I would not advise any one to make his own hives and supplies.

I intend to lay up the brace-walls on the east side of my bee-house, and grade up

FIG. 1.—Set up ready to extract with porcelain-lined kettle and washtub in foreground.

to the siding. I have 160 colonies in the yard at present. The picture was taken about Sept. 10, at the close of the buck-wheat flow, after some of the supers had been taken off.

The third and fifth colonies in the second row, beginning at the right, produced about 150 lbs. of clover and basswood honey each. The fifth colony in the fourth row, beginning at the right, with two supers on, is a ten-frame hive which produced 100 lbs. of clover and basswood comb honey in beeway sections. I had a number of colonies in the apiary that bore equally well. Most of the colonies that ran for extracted honey averaged about 25 lbs. per week during the clover and basswood flow.

Cohocton, N. Y.

A LIGHT PORTABLE EXTRACTING OUTFIT

BY H. D. MURRY

Some beekeepers hesitate to start out-yards because of the expense of maintaining a separate extracting outfit at each yard, or because of the trouble of hauling the ordinary outfit from one yard to another. To such it may be interesting to know of a light outfit that I use. The whole thing does not weigh more than 150 pounds, yet it is effective and convenient.

The extractor is a Cowan reversible, No. 18, with comb-baskets large enough to take two frames each of the shallow frames we use in the production of bulk comb honey. These frames are $5\frac{3}{8}$ inches deep. We use them also for extracting; and, although the extractor has only two comb-baskets, we put in four combs at a time, making it equal to an ordinary four-frame extractor. The uncapping-can consists of two galvanized iron tubs of such size that one will just slip down about an inch in the top of the other. We cut out the bottom of the upper tub, leaving an inch or so all around, and put in a bottom of galvanized wire, about four meshes to the inch. A strip of board three inches wide which runs through the handles of the upper tub completes the uncapping-can. Our uncapping-knife is a Bingham of the "vintage" of 1897. It has a much thinner blade than those turned out now, and does much better work. We do not use any water, either hot or cold, as we do not need it with this knife.

For the purpose of catching the honey from the extractor, we use a galvanized iron can 12 inches in diameter and $12\frac{1}{4}$ inches deep. We tie a cheese-cloth over the can and set it under the gate of the extractor. When full it holds a little over five gallons. There is a molasses-gate near the bottom of the can.

Our uncapping-can will hold all the cappings for one day, the honey running through the wire bottom to the tub below, which must be emptied from time to time. At the close of a day's work we empty the lower can; and by morning, in this hot climate, the honey is practically all out of the cappings. We have found that any honey that might drain out afterward is too dark to suit us. We then melt up the cappings in a porcelain-lined kettle and squeeze out the wax with two boards fastened together at the end. The wax is caught in another galvanized tub, and the slumgum may be saved in a sack to be run through a wax-press later. There is very little wax left where nothing but cappings is melted up. These tubs, with the kettle and honey-can, all nest together, so that they take up only the room in a wagon that one tub would occupy.

We are engaged mostly in the production of bulk comb honey; but we have to have extracted honey to pack the comb, and we find this outfit entirely adequate to our needs. The entire cost is only about twenty dollars; and, being so light, we can put it on a wagon with empty cans enough to hold all the honey our crew will pack in a day. It can be set up in a few minutes after we reach a yard, and we are ready to go to work.

If anybody wants an outfit that will cost \$150, and take a pair of good mules to pull,

he has my permission; but I have not yet felt the need of such an outfit, and I prefer to use that money in keeping more bees.

Mathis, Texas.

[Mr. Murry does not say how much honey he can extract in a day with his outfit; but since he produces only enough extracted honey to use in packing his bulk-comb we have no doubt but that the outfit has capacity enough.—Ed.]

A PORTABLE EXTRACTING-HOUSE LARGE ENOUGH FOR A POWER OUTFIT

BY V. V. DEXTER

I am using an extracting-wagon which is very satisfactory. It is rather low, but at the same time it pulls easily over the average road. The floor is 7 by 14 feet. The top is about 6 feet high, and made of canvas over a frame of 1 x 2, with 2 x 2 corners, and braced with wire. The whole does not weigh more than the ordinary wagon and hay-rack. I use this wagon not only for extracting, but also for a shop, bunk-house, and dining-car, or whatever I need it for at the yards. As I have no building at any of them it is fine to have a cool bee-tight house to take with me on my trips. I work alone, and care for 450 colonies.

This wagon is exceptionally good in moving bees. I never close the hives. I simply

FIG. 2.—Packed ready to move, with a cake of wax from the tub leaning against the nest of tubs.

Dexter's extracting-wagon, which is large enough for gasoline-engine, capping-melter, etc.

drive up to the yards, take off the horses, load up, shut the door, hitch up again, and drive off. Not a bee can get out; and if a few do leave the hives and fly to the windows, it is easy to give them to the weakest colony when they are unloaded in the new yard; but I am not bothered that way unless it is necessary to stop some time while on the road.

HEATING HONEY AS SOON AS EXTRACTED TO RETARD GRANULATION.

In extracting I use a Gilson engine, four-frame extractor, steam-knife, capping-melter, honey-heater, and storage-tank under the floor. The honey is pumped from the extractor to the heater where it is heated enough to avoid granulation, also to remove all specks. From there it runs to the tank under the floor, the tank being large enough to hold one-half to a day's extracting; and as the honey is warm, it is only a few minutes' work to run 1200 or 1500 pounds into cans ready for market. Heating the honey when it is first extracted does not injure the flavor, as it is apt to do if left till after granulation. I have had alfalfa honey remain clear a year because it was heated *when first extracted*. It is practically impossible to get all the specks out of our thick honey unless it is heated.

My old plan, and the plan of many western beekeepers, is to strain through window-screening at the time of extracting, and, later, heat and strain through cheesecloth. By the method I now use, the honey takes care of itself till the end of the day, when it can be canned ready for market.

In the picture the tank under the floor does not show, as it was removed after the extracting was done. The door in the front end has been taken out also. It is of cloth, and can be easily taken off.

Practice has proven to me that the front end is the best place for the door. With a slide it is possible for one man to put from twelve to sixteen full-depth supers into the wagon without getting in himself to arrange them. In removing empty supers it is also easy to remove almost as many without the trouble of climbing in.

North Yakima, Wash.

PAINTING QUEENS SO THAT THEY MAY ALWAYS BE QUICKLY FOUND

A Quick-drying Non-injurious Paint that May be Applied with a Wire

BY H. BARTLETT-MILLER

Nothing "straight from the beeyard" having appeared in any of the journals to guide the would-be queen-marker in the somewhat fearsome job of making our black and leather-colored majesties easier to find by means of paint, I determined this spring to find out for myself, and brand every queen in my home yard of 186 colonies. My knowledge that this was possible was gained from a notice in the *Review*, that clear spirit varnish is used to mix the color with. At best this advice was very vague. Some spirit varnishes would kill a fairly strong dog, let alone our delicate queens. Knowing most of the stunts in making spirit varnishes, I decided to use a simple tincture of benzoin, this being merely pure gum benzoin dissolved in alcohol. It can be compounded by any chemist, and a quarter's worth will last a thousand-colony man eight or ten years unless he paints the workers.

This solution of benzoin has a strong but very pleasant scent; and if odor had much to do with our queens, the scent of the benzoin would have led to all mine being promptly balled, whereas not one met such a fate. Its peculiarity for our use is that the paint is dry and washable in a few minutes. In fact, 30 seconds suffices to dry quite a thick application on the queen.

Having obtained a clear liquid tincture, use any dry color you fancy, taking care to avoid red lead or even white lead, as either may kill either the queen or the bees which might try to lick this decoration from the queen's back. I took dry-powder lemon chrome, of which any painter will sell, for a few cents, a sufficient quantity to last a lifetime. It costs about 14 cents per pound.

Take a very small domestic-essence bottle and a piece of wire (say one strand of barb wire) cut off enough to reach to the bottom of the bottle, and to stick up a quarter of

FIG. 1.—Home apiary of Daniel Danielson, Brush, Colo. Through the center of this apiary runs a track for the hand-car shown, which is used for carrying supplies in and out of the yard.

an inch through the cork, through which it must be pierced. Bend the wire over to prevent the cork from coming off. Now flatten with a hammer the other end of the wire to make a spatula with which to apply the paint.

Fill the bottle about half full of tincture, and drop into it any coloring matter handy. Half a saltspoonful of liquid bluing does very well. If you have to use a dry piece it acts just as well. This washing-blue alone I find is too dark. Queens marked with it are very little easier to find than if unmarked; so, mix a little whiting, chalk, dry white clay, or any thing that will lighten the blue, and remember that it dries considerably lighter than it appears in the bottle. Mix yellow and washing-blue for green, as powder greens all contain either copper or arsenic, and we wish to run no risks with poisons, either with our families or bees. The coloring matters are not dissolved in the tincture of gum benzoin, but only mixed in it, and the benzoin only acts as a fastening medium after the spirit has evaporated.

Now for the last time, let us hope, go through the time-honored and time-wasting task of finding madame by adopting the sifting-through-the-excluder method, which is the best idea, except branding, that I have hit upon. Be careful, after the last frame is shaken, not to smoke riotously the bees with a view to hastening the departure of the bees to the lower regions. This was

an error I fell into. Too much smoke so demoralizes the bees that they boil over the top of the empty body into which they have been shaken, and her majesty goes with them, and you "dunno where she are," and she has to be let alone while you make another trial elsewhere. Just smoke *gently* the top edge of the body, and keep on going all around it, and in short order the bees will keep turned head downward, and very quickly get through the excluder.

Having pounced upon the cause of all the roar and hubbub, grasp her with finger and thumb by the thorax as though you meant to clip her. I always clip mine, if needing it, at the same time as branding, and with the bottle-neck curled tight in the little finger of the same hand draw the cork with the other hand and apply a fairly liberal dose of the liquid paint on top of her thorax, and a little on the end half of the wing left unclipped. One would think that any bee, black or yellow, carrying a dab of bright yellow paint on her thorax nearly an eighth of an inch square would be seen at once on the most crowded frame; but let madame jam herself between the comb and bottom-bar, and she may hide there all day before you see her; but the colored wing seems to show up directly.

Any way, after branding my first twenty on the thorax only, a week's heavy weather followed; and going over them to test the new adventure, and to count the supersedings, I found none of the latter, and all too

FIG. 2.—Danielson's International auto-wagon, loaded ready for a trip to an outyard.

few of the branded queens—that is to say, without more searching than I had thought would be needed. So I “put some more on,” and this time on the end of the wing as explained above, and, presto! “she could not be hid.” It was a bit of fun to watch the frantic efforts of first the queen and then the bees trying to make mother look less “dudish.” The queen’s antics reminded me of a rooster paying court to a hen, dropping one wing and sweeping the ground

with it. She tried and tried for fully a quarter of an hour between the sweeping business and fanning to try to unburden herself of this unusual encumbrance. However, three weeks after, they had all grown used to “having ’em all on.”

Now, the greatest surprise I received during the whole business was the attitude of the workers toward the queen running fairly fast over the comb, carrying what I declare none of them ever saw the like of

before. The scent, too, was strange to them. According to all we are told, the workers ought to have promptly taught that queen proper manners, and to have made her realize that to royalty such “hyper scentsiveness” was entirely out of place. Instead of that, all who could kept up with her and attempted to lick off the fast-hardening brand.

I do not like to suggest to the editor that it was the alcohol they were after; but in the first few cases, lick it off they certainly did, and with very evident relish. So I learned either

FIG. 3.—The same truck shown in Fig. 2 transformed into a pleasure-car.

Another caution is when marking the wing. Be careful not to daub the abdomen. If the square end of the flattened wire is just touched on the wing ever so lightly in the center of its length, the wire marker can be lowered till the wing moves toward the marker. When drawing it away it brands the wing. Try a few drones first. Do not be content with the thorax mark alone. If you can see a queen with that mark only, you could, in the case of yellow queens, find her with no mark at all. My queens were marked at the spring overhaul, when no drones had yet hatched. All are very dark, being granddaughters of a queen imported thirteen thousand miles from Italy, and a few queens are black. Old queens were marked with the lemon chromo.

This season's queens are being marked with the washing-blue made lighter by addition of whiting used for fire-places. Young queens just laying are an exception to the calm behavior noted on the part of the older queens. The clipping and branding so excite the little "newly weds" that in two cases, while some bees were going for the "whisky" on the thorax, others were balling the queen, and I had to use a deal of smoke; and while all were roaring, I shook the queen with a frame of bees at the entrance, and let them all run in together. But the five or six that acted in this way were laying serenely the next morning.

All together I found and branded queens from the whole apiary of 186 colonies in four days, doing a few other items of manipulation as needed, such as filling supers lacking a few combs, and arranging brood in supers when necessary. I judge that one man ought, by the sifting method, to find and brand five queens per hour. But if

to hold the queen until, by the dullness of the paint, I knew it had dried, or else I let her wander around for half a minute on a bare comb. This half-minute seems a much longer time when you have three or four days' branding to do in front of you; but unless the alcohol has quite evaporated you will find your queen, when next you go to her hive, with only the remnants of a brand—far too little to be of practical use to the large apiarist.

A word of caution to the nervous: Brand the queens when holding the abdomen—not the head—toward your right hand. I branded one head toward me, and daubed the end of one of the antennæ. I found queen-cells four days after, and no queen. I had noticed this bungling on my part, and had marked the hive for future investigation.

you do not happen on her majesty when glancing over the combs as you lift them out to shake, don't waste time looking any more for her; but shake away. Make very sure, too, that your excluder is nailed securely to the bottom edge of the hive-body you use. Don't trust a framed excluder loose. You will bump the body over the edge, and your queen will be gone like a flash. Out of my lot I lost only the one whose antennæ I painted over eleven weeks ago. No branded queen but that one has been superseded, so that the wing-branding can be no detriment.

Kihikihi, Waikato, N. Z.

[We see great possibilities in "branding" queens. A queen easily found at almost any time ought to be much more valuable than one not marked.]

Without having tried it ourselves, we should think that red would be the most conspicuous color that could be used, with green, perhaps, a close second.—ED.]

THE INTERNATIONAL AUTO WAGON FOR OUT-APIARIES

BY DANIEL DANIELSON

A request was made in GLEANINGS some time ago for ideas from beekeepers who make a practice of running for extracted honey with outyards, and who carry the honey home in the combs before doing the extracting. That is just what I am doing.

I got an International auto wagon, as the pictures show. I have four outyards located from three to twelve miles from home. I carry all my extra hives and supplies on the auto to the outyards, and the honey home in the combs, and the empty combs back.

Fig. 1 shows my home yard with a hand-car on the track, myself sitting on it.

Fig. 2 shows the truck loaded with hives ready to start for the outyards.

Fig. 3 shows the same vehicle ready for a pleasure-ride.

I have done away with all hive numbers and all book-keeping and records, as they are time wasted. I use bricks, as the drawing shows, and I find that they answer the purpose very well. Something is needed to hold the covers on any way, and two bricks will do it in the strongest wind. When I come to the yard, there the record of all the hives is right before me. The bricks show the condition the colony was in when looked at last. I can not see nor find any thing more handy. I have used this method for ten or twelve years.

Brush, Colo.

THE EQUIPMENT OF A SMALL HONEY-HOUSE

BY JOSEPH GRAY

In the ideal small honey-house there should be a platform in the southwest corner of the building 18 inches or any other height desired. Mount the extractor on it with the gate over the tank below, and just east of it, locate the uncapping-can.

The tank is placed below the platform, and a pit is dug in order to facilitate the drawing of honey from the tank. The tank has a division at the east end, with a one-inch honeyway beneath it. By this gravity process all the scum is left at the west end of the tank, and the clean clear honey is drawn off at the northeast side of the tank. Quarter-inch screen wire over the tank, in at least two sections, gives ready access to the tank, and renders it mouse-proof. Cheese-cloth on this screen forms the honey-strainer and renders the tank bee-proof.

The honey is brought in through either door, and one may choose between lifting the supers or bending the back and lifting the combs. No honey is handled heavier than a comb until it is placed in the 60-lb. cans. If a 3-ft. tank is not sufficient ea-

A double-walled honey-extractor. The space between the two cans is for water, and it takes the place of the water-tank of a gasoline-engine. The water gets hot enough to warm the honey so that it strains easily.

capacity, a 6-ft. tank extending under the platform can be installed. An excellent storage place is found beneath the east end of the platform for honey-cases, etc.

The screen windows are on the east and west. The screens should come 3 or 4 inches above the opening, and $\frac{3}{8}$ to $\frac{1}{2}$ from the side wall. In the morning the bees, both inside and out, are attracted to the east window; and the scent coming direct from the screen does not attract the bees to the exit 4 inches higher up. In the afternoon the bees are attracted to the west window, and so your extractor, etc., are always free from bees; whereas if the screen is placed directly over the extractor more or less bees will be constantly falling in.

I particularly wish to call attention to the door. Never make a screen-door. Let it be solid, so that as few bees as possible will be attracted to its locality. The same idea is followed in the door as in the screen. The door west, being in the shade during the morning, will attract fewer bees. The door east, being in the shade during the afternoon, will attract fewer bees.

Bakersfield, Cal.

THE INTERNATIONAL AUTO WAGON AND PORTABLE EXTRACTING OUTFIT

BY J. E. FARR

If the owner is the driver, and a careful driver, and if he uses one of the International Harvester auto wagons with a high wheel and solid tires, I find there is a saving over the feed of a horse. The horse will cost about 75 cts. per day for feed if you feed him properly. Furthermore, your time is lost, principally on the roads. To do the same work, gasoline costs less than the horse-feed, and nearly all the time on the road is saved.

My west yard is equipped with two buildings. One is a store-house for combs, and the other an extracting-room. I equipped this building with as good an equipment as money can buy. I use an eight-frame automatic extractor driven by a two-and-one-half-horse-power Sandow engine. A rotary pump conveys the honey through pipes to 1000-lb. storage tanks, six of which I have in the one yard.

I thought of hauling combs here to extract, and I tried the plan to my sorrow. Just think of making a trip to an out-apiary, taking off perhaps 1200 lbs. of honey, drawing the combs to the central yard after you are exhausted lifting them on the wagon or truck! You do the same heavy lifting at the other yard, and then return

the empty combs after you have washed out your wagon or car, which must be done to prevent robbing. Furthermore, I use thick-top unspaced frames, and I was disgusted at the appearance of those beautiful combs, all bruised and jammed out of shape. If one used shallow self-spaced frames, perhaps they would stand the hauling, but I can not afford to lose the time.

We have a portable and collapsible honey-house, 6 x 6 x 14, which can be moved on a low wagon just as it is. It may be folded down on the bottom. The ends are made of square frames of 2 x 4 stuff, sealed with pine flooring. The lower half of the sides is covered with paroid roofing, and the upper half with wire screen; and I use white oilcloth for curtains, also for the top half. This space is enough to allow the equipment which I have before spoken of, only I use two 1000-lbs. tanks and remove the honey into the cans each morning. This allows the honey to settle over night. As fast as I fill these crates of pails they are loaded on to the truck and left right there until the day's work is done; then for our evening job they are hauled to a barn for storage.

Low Banks, Ont., Dec. 3.

A COMPLETE EXTRACTING-OUTFIT

The Use of Capping-melters, Strainers, Pump, etc., at Out-apiaries

BY E. L. SECHRIST

F. R. Beuhne, on p. 489, Aug. 15, 1911, has, I think, stated the case fairly for and against the capping-melter. During this season I have used three capping-melters, one being the Severin, described in GLEANINGS, page 722, Dec. 1, 1911. The others were the combined melter and McIntyre uncapping-box described on pages 406 and 410, July 1, 1912. Comparing the two, the Severin is small and easily moved. The other is bulky, and adapted only to a permanent location. The Severin requires a two-burner stove, as all the honey contained in the cappings must also be heated while melting the cappings. The combined melter, on account of draining off much of the honey before melting, requires only a one-burner stove, and much less honey is darkened by heating. Again, it is much easier to uncap into a large box than into a small melter like the Severin. The combined melter also takes care of all the drip from uncapped combs waiting to be extracted, so that there is no dripping of honey any-

where but in the one box (all the sticky mess in the one box), and no handling of any thing but the honey as it drains off, and the cakes of clean wax as they come from the wax-separator.

I have been much pleased with the Severin wax-separator. The honey is separated from the wax at once, and the wax is produced in clean uniform cakes free from slumgum or honey, and ready for the market. It means something not to have to remelt and mold from three to five hundred pounds of wax yearly.

The engravings show the arrangement of my extracting-house. From the power extractor the honey is pumped to an elevated water-jacketed heater-tank. I was unable

to operate the pump satisfactorily on our thick cold honey until it was connected with the extractor-shaft by chain and sprockets, and then it *had* to work. As the honey comes from the pump it passes through a coarse-mesh screen in the top of the heater-tank, which catches any large bits of comb, etc.

Being heated in this tank to about 100 degrees it will readily pass through a fine cheese-cloth strainer. I prefer the Pettit improved square strainer, which has eight square feet of straining surface, nearly all of it vertical. It is illustrated in the *Review* for Jan., 1910. It is far ahead of the round Pettit strainer or any other I have tried. I use it with an additional, very

loosely fitting basket of window screen inside the cheese-cloth. This catches all the scum, bits of wax, etc., which otherwise would soon clog up the cheese-cloth. I have used one strainer continuously, not changing the cloth during a day's run of about 2000 lbs.

The strained honey runs into a covered storage-tank, and, as time permits, is drawn off into the can-filler through a two-inch gate. This large gate permits a rapid flow into the filler which is merely a square can marked at height to hold sixty pounds, and with a bottom sloping toward the outlet. This outlet drops a quarter of an inch into the mouth of the five-gallon can, and is screened with a $\frac{1}{8}$ -inch-mesh netting to prevent flying bees from dropping into the can when it is being filled. Simply let the honey flow (through a wide open gate) into the filler up to the mark; pull the plug which closes the hole in the bottom of the filler, and go about your business of nailing up cases, or whatever it may be, and, when you are ready, drop in the plug, replace the full can with an empty one, and run the filler full again. With this plan there is no lifting of the extracted honey until it is in the can ready to put into the case. This arrangement for extracting has been a labor-saver for me, as I have, working alone, taken off the hives and extracted in one day 2500 lbs. of thick sealed honey, running nearly all of it into sixty-pound cans.

I bought a second-hand Sears light delivery truck this season; and, although it has given me considerable trouble, I believe there is no other business into which an auto fits so well as beekeeping. It is only fair to say that the truck runs much better now than when I bought it. At one yard I hauled filled supers half a mile to be extracted, and returned the empty combs to the yard. This was very satisfactory; and if roads were good I should like to try hauling every thing to a central plant, which could be thoroughly equipped. Our roads are so bad that it seems advisable to have a fairly complete outfit at each yard.

OPERATION.

Filled supers are brought into the house through the solid door (no screen, and piled wherever desired in galvanized iron trays a little larger than the super, and one inch deep, which catch all the drip.

The operator stands at X, within easy reach of a pile of full supers at A, extractor at D, and super for empty combs standing in tray at E. A second uncapper may stand at the opposite side of the box, near G F. is a gallon can containing water for

washing sticky hands, etc. It is hung on a nail on the side of the uncapping-box. G is the boiler for the steam uncapping-knife. Cappings fall on the screen at B, and, after draining as long as may be convenient, are pushed toward the left, off the screen, on to the heated surface of the melter at C, from which the melted mass flows into the wax-separator I. A pail at K receives the honey flowing from the wax-separator. If extracting light honey this should be kept separate; otherwise it is poured directly into the strainer.

The honey draining from cappings, unheated, passes through a trough into the pail at H, and is two-thirds or more of all the honey contained in the cappings, depending on the time it is allowed to drain before melting.

From extractor D, pump L raises the honey through a two-inch pipe for the horizontal run, to lessen friction, into the heater-tank M. A pail at T may be used to handle the honey if the pump is not working. A coarse-mesh screen catches bits of comb, etc., that go through the extractor. This heater-tank has a double water-bottom with a series of channels through which the honey runs, and is heated on its way to the gate. N is a square Pettit strainer through which the honey runs into the covered tank P, then into the filler tank R, and into the sixty-pound cans.

With this plan, all combs are kept in the end of the house nearest the entrance, while all canning of honey and storing of empty and filled cases is in the opposite end near the exit, from which the filled cases are loaded on the wagon.

The bees brought into the house fly to the long screen windows and escape through bee-escapes, or into trap boxes until the work is finished.

Fair Oaks, Cal.

OUT APIARIES AND EQUIPMENT

Packing-house for Extracted and Bulk-comb-honey Production

BY J. J. WILDER

The size of out-apiaries makes all the difference in the equipment. It matters not whether they are operated for comb, bulk comb, or extracted honey.

If the honey flora is abundant, large apiaries can be established; and it would be more convenient and economical to have adequate equipment at each apiary.

But if the honey flora is limited, and only small apiaries can be kept, it is better to have one good equipment at the home yard.

If, however, a great number of small apiaries are in operation, there should be suitable equipment at the most central apiaries, and the surrounding ones worked from those centers. If the apiaries are very small, consisting of only 30 or 40 colonies, it is not economy to have even a small building at each yard.

If, on the other hand, the apiaries consist of 50 to 60 colonies or more, it is more economical to use a small cheaply constructed building at each yard in which to keep supplies which are ready for use, and which can be hauled from the main yard, and housed during the more idle time, and be there in readiness for the rush. All supplies not in actual use can be put in buildings of this kind, and protected from the weather. I am speaking from experience and for the South.

As to what the equipment should consist of, it depends partly on the kind of honey produced. But let me first say that at the home apiary and the central outer apiaries there should be at least a cheaply constructed workshop large enough to work in and to hold the stock of supplies, both in the flat and after they are in readiness for the surrounding apiaries. This building should be separate from the honey-house, but near it.

CONSTRUCTION OF HONEY-HOUSES.

Now about the construction of honey-houses economically and for service. A honey-house should consist of not less than two rooms or two separate apartments. Two rooms may be built large enough to suit the room requirements of almost any bee business.

The floor of the rooms should be within a few inches of the surface of the earth,

and the floor in the packing-room, at least, should be made of cement, and the sills of the building should rest on a solid brick or cement foundation unless good lasting wood material can be obtained. The material used for siding should be matched or well stripped about the joints; and it is needless to state that the building must be bee-proof throughout—even the wall or partition between the two rooms.

There should be a solid door not less than 3 ft. wide between the two rooms, and one of the same dimensions on the front side of each room, opening from the outside, with sliding screen doors on the inside.

Each room should have not less than two large glass windows, one opposite each door on the side, and one in each end of the room. The entire opening should be covered with screen wire.

A wide smooth shelf or bench constructed across the side of the room opposite the doors will be necessary. In the packing-room this bench is convenient for packing honey, and in the other room it is used in cleaning supers. We call this our super-room. In honey-houses constructed for extracted honey we call this the extracting-room.

The floor of this room is elevated about 4 ft. above that of the packing-room, and steps lead up to it from the door in the partition. We plan for a slight elevation in front of the outside door of this room, in order that honey may be unloaded on a level with the floor. We usually build this room up on pillars of the proper height, and leave it open underneath or remove some of the earth from beneath, and make a storage-room of it.

The honey-tanks are inside the packing-

room; and on the other side of the wall up in the extracting room is mounted the honey-extractor, and from it the honey runs through pipes in the wall into the tanks below, from which it is bottled, canned, or barreled. The uncapping-tank also rests against this wall, and the honey passes from it to the tanks in the same manner.

A similar house is constructed and equipped for bulk-comb-honey production. The honey-tanks stand up on two strong pieces of timber with sufficient upright pieces of the same material to support the tanks, which are well braced, leaving it all open under and around the tanks.

If we are fixing up the packing-room for packing bulk honey we erect a platform near the end of the frame, on which the tanks rest, next to the steps. The supers of honey are brought from the extracting-room, where the honey has been graded.

SLIDING SHELF AND TROUGH.

Next in importance is the trough, which is zinc-lined, or made water-proof, with a honey-gate at the rear end. The bottom is so put in as to be about two inches on the decline to it. This trough is movable, and rests on timbers so it can be moved up or down a few inches to suit the height of the vessels to be filled. It rests about three or four inches back under the honey-gates of the tanks. The cans to be filled can be passed just under them on sliding shelf No. 3. About two inches from the top of this trough, on either side, is nailed a strip $1\frac{1}{4} \times 3$ in., and sliding shelves No. 1, 2, 3, and 4 rest on this strip. These shelves are formed on rims made of one-inch lumber about 3 in. wide, which just fit down between the strips on the trough, leaving

about $\frac{1}{4}$ in. of play; and on either side of these rims, even with the top, is nailed a strip $13-16 \times 1\frac{1}{2}$ (see diagram). This forms the slide, and on top of this is nailed the shelf, which makes it just a little above the top edge of the trough, and they can be lifted out or moved along in it as may be most convenient. The honey that may accumulate on these shelves can be scraped off or it will run off into the trough.

Now, regarding the use of these shelves on which all our bulk comb honey and most of our extracted honey is packed, shelf No. 1 is covered or made of slats on which the supers of chunk honey are placed, one at a time, at the right of the packer, who stands in front of shelf No. 2. This shelf has a heavy zinc covering over it, on which frames of honey one at a time are placed from No. 1, and the honey is removed by passing a sharp knife around close to the frame. The frame is then removed and placed on the frame-rack over the tanks, to drain for a while. The honey is then cut in strips the size that will best fill the utensils through their mouths endwise. Thus wider strips may be placed in a larger-mouthed vessel, and smaller for small ones. The strips of honey are lifted from the shelf by passing the blade of the knife under them one at a time, and placing them in the vessel until neatly filled. The can which is being filled is held with the left hand, and then is set on shelf No. 3. This is the duty or task of packer No. 1.

Shelf No. 3 is covered with fine screen twice double, which passes all the way around the frame. It is drawn very tightly and is nailed securely. Then the strips on either side, upon which it slides, are nailed on.

Packer No. 2 passes the vessels thus filled, one at a time, on this shelf under the honey-gate, where they are filled with extracted honey, after which they are set on shelf No. 4, which is covered solid with a board. Here the honey is sealed and labeled. Any honey that may be on the outside of the cans is cleaned off, and they are put in crates ready to be nailed up. This is the duty of packer No. 2, and these two packers put up nearly 2000 lbs. per day.

Shelf No. 2 has a slightly oval surface, so the honey oozing from the cut comb will run off; and when it does not, it is quickly removed by passing the blade of the knife over it.

Shelf No. 3 has a smooth surface. All the honey that may drip from the cans, which is usually a considerable amount from both the honey-gate and the work of packer No. 1, will pass down through it into the trough.

All the best extracted honey is run into tank No. 1, and is packed with the fancy comb honey in glass vessels. The darker grades of extracted honey are run into tank No. 2, and are packed with the off grades of comb honey in tin vessels. Also the honey from the uncapping-tank runs into this tank. When we are filling cans at tank No. 2 we arrange the sliding shelves about it in

the same manner as we do at shelf No. 1. I use the common galvanized 3-inch water-conductor pipes to run honey into the tanks. The conductor running from one to the other is about two inches above the tanks, and the one running from the extractor runs into it. This conductor is separated by the one from the extractor where it passes through the wall; and if we want to run the light honey from the extractor into tank No. 1 we raise the end of the conductor over tank No. 2, and it turns the honey into it. This is done by the man at the extractor by means of two cords, one attached at each end of the conductor. These cords pass up through the wall at the most convenient place for the man at the extractor, who can change the current of honey by loosening the cord for one end and tightening the one for the other.

Cordele, Ga.

GETTING BEES OUT OF SUPERS WITHOUT A BEE-ESCAPE

BY C. A. BUNCH

Last season I used a simple device in taking off one and a half tons of honey for clearing supers of bees quickly, which does not demoralize the bees in the hives, but leaves them in fine condition to defend themselves.

The drawing makes the plan clear. I used a ten-frame full-depth super, and on the under side, $\frac{3}{4}$ -inch apart, I nailed two

square sticks in the center. Then I cut two thick pieces of wrapping paper, 8 inches long, which I tacked to the upper side of the super; then I brought the lower edge down and tacked it to the parallel square sticks, thus making a V-shaped arrangement with a narrow slot at the bottom.

I set this prepared super on an eight-frame super, and cleated both ends, which made it ready for use. When I am ready to take off honey I set the whole thing near the hive, remove a super and set it on the

cleaner (placing a robber-cloth over the hive if necessary). As I use loose hanging frames without spacing devices I loosen all of them with a screwdriver and slide them over toward the opposite side of the hive. Then with a head of broom corn I begin brushing the bees down without taking any frames out of the hive, pulling them over toward me as I get them clean of bees. When the bees strike the incline below they slide down and out of the slot into the eight-frame super before they can take wing, and most of them will be clustered below. There are cleats across the end of the super to furnish a grip for the hands, and I empty the bees out by lifting the super and giving it a sudden jar on the ground in front of the hive after all of the supers have been cleared of bees.

Of course I use some smoke at the time when I begin brushing. As soon as the nearest side of the first comb is free from bees I pull it over toward me, then brush the bees from the opposite side; then go to the next one, etc.

Lakeville, Ind.

HONEY-TANKS BELOW THE EXTRACTOR

Moving the Extractor from One to the Other

BY J. D. EVANS

My bee-house is 16 x 25 feet, and 7 feet high at the eaves. There is a stone wall under all. There are two floor levels, and at the south end 4 feet 6 inches lower than at the north end. A stone wall separates a hold-up of earth at the north end. Across the lower half is a plank bench on which six tanks holding 500 pounds each can be placed. This platform is two feet high, and leaves room for scales and a 60-lb. can into which the honey is run from the tanks. The extractors stand on the high level; and the honey, as fast as it is extracted, runs into the tanks, which are covered with cheese-cloth. This is all the straining required, as the honey is left in the tanks until they are required for the next extracting. I think a strainer in an extractor must be an abomination. When one tank is filled the extractor is moved to another place, and so on until all are filled.

My house has five windows—two in the west, two in the east, and one in the south gable. Two doors opposite each other are used. The yard is on the west of the bee-house, and the floor is level with the ground on that side. On the east side the land is about three feet lower than the doors, which makes it handy in loading the honey or taking in supplies.

I have a chimney on the north end, and a stove for melting wax or making feed. I have a floor 7 feet above the north floor, and one 9½ feet above the south floor. These floors do not quite meet in the middle; and as one is 2½ feet higher than the

than the occasional trips demanding service in the capacity of hauling bees.

Bees hauled in daylight would be safer if covered over with tarpaulin, or curtained down all around. A lighted smoker at hand will save time where a leak occurs.

WINTERING REPORT.

I have just inspected 88 colonies of bees, and find some loss, owing to warm January (39 degrees average), followed by the severely cold weather the first half of February. Fifteen colonies were lost; twenty had to receive combs from heavy ones, of which there are still over 40 in first-class condition. Some colonies lost had considerable

brood and honey. Does water carried in for feeding cause extra exposure? or when brood is started and the cold weather prevents any more trips to the source of water supply, does loss result? We have water in a ditch ten feet from the hives. Temperature 65 degrees, no pollen; bees robbing and hunting honey where bees are dead.

Evansville, Ind.

[We do not know that we quite understand you when you ask, "Does water carried in for feeding cause extra exposure? We suppose that what you mean by this is, "Does the water carried in cause more brood-rearing, and does that extra brood-rearing require the bees to expand their cluster to a larger size?" Yes, in such a case a cold spell coming on would do damage to the cluster and to the brood. We do not think water is absolutely necessary for brood-rearing, because we have had a large amount of brood hatched in our cellars. Last winter some colonies began brood-rearing in December and January; and when we took them out on the 12th of March they were much stronger than when we put them in. The bees were bright and healthy. Certainly the bees in the cellar could get no water except what might have condensed under the hive-lids. At one of our cellars there was some condensation, for water stood in drops from some of the hive lids; but in the other cellar, where the temperature was higher, there was no condensation, but brood-rearing went on just the same from December to March 1.—Ed.]

other, with an ordinary step-ladder costing 75 cents there is no trouble in getting upstairs; and I can stand on the floor of the extracting part and hand up any thing I wish to the south upper floor; and when up I can pass it over to the north floor.

This house is bee-proof and mouse-proof, and the combs are stored in winter in the lower level, nine stories high. The upper floor south is cut back over the step so as to leave head room. The diagrams will illustrate this.

Islington, Ont., Feb. 1.

THE AUTO TRUCK FOR MIGRATORY BEE-KEEPING

BY W. W. VICKERY

There have been some inducements for migratory beekeeping in our river-bottom cornfields, where, by selection at favorable fall seasons, we command pasturage almost solid with vines and other honey-plants on 3000 to 4000 acres, all cornfields, every acre of which is honey-bearing.

The auto truck has been a quick and convenient way of moving bees to and from these fields, and it often saves two hours on a six-mile and return trip.

Hives should be bound with twine and securely screened, and, if moved at night, promptly after loading, are not apt to smother if properly ventilated. I would advise extra care in tying the load on firmly in addition to the wrapping of hives. The vibration and danger of bumps in the road would make stapling unsafe.

There has been a much greater test on our Reo truck in delivering groceries every day

Heads of Grain from Different Fields

Making Labels Stick on Tin; Beehive Scales for Recording the Honey-flow; Entrance-controllers; Bees vs. Cane Sugar for Bees

1. I have trouble in making the labels stick on the honey-pails. They always come off as soon as dry. Is there any preparation made that will make them stay?

2. Are the ten-frame hives made wider now so that we can use a division-board? With the ten-frame hives I now have it is almost impossible, especially in the fall, to get out the first frame.

3. I notice in my Swiss journal a scale made on purpose for beekeepers, and also entrance controllers. These platform scales would surely be much handier than the scales we have. The entrance-controllers made out of steel screwed on the hives and left on the year round would be much better than wooden blocks.

4. How much do you consider a colony of bees worth in a well-painted ten-frame hive in the early spring, having wired worker combs?

5. The past season I had a very unusual case with a young queen. While putting back the last frame I noticed the queen hanging on to a frame apparently dead. I picked her up, held her in my hands for about five minutes, when she commenced to show a little life; then in about five minutes more she commenced to take short breaths. Then I put her on top of a frame. The bees started to feed her, and in about ten minutes more she seemed to be all right. It certainly looked as if she had actually fainted. I am absolutely certain I did not hurt her while manipulating the frames. What do you think could have been the reason of her acting so strange? The bees were somewhat cross, and I had to smoke them considerably. Could it be that the young queen was so frightened by the smoke that she seemed just like dead? In my twenty years of beekeeping I have never seen any thing like it.

6. Recently I read in a farm paper that sugar syrup made from beet sugar, and fed to the bees, will kill them during the winter. Is there any truth in the above statement?

7. Do you consider the metal-spaced Hoffman frame superior to the regular Hoffman frame?

8. What reasons does Dr. Miller give for not painting his hives?

G. A. BARBISCH.

La Crescent, Minn., Jan. 21.

[1. It is very difficult to make labels stick upon tin unless the labels go clear around the tin package itself. You can purchase a dextrine that answers a very good purpose, 3 oz. for 5 cts.; ½ lb., 10 cts. Some have recommended using a little honey in connection with the dextrine.

2. The ten-frame hives are now made wider so as to take in the division-board the same as the old eight-frame hive used to do, and does yet, for that matter. We do not regard it as practicable to have contractible entrance-closers, as we believe that all such devices of that kind are a useless expense. An ordinary block with an opening on one side is very much cheaper than and quite as effective as contrivances that cost many times more.

3. Most of the spring-scale concerns in this country furnish good scales for platform work and for weighing hives of bees while the bees are gathering honey. You can secure such scales from your dealer in bee supplies.

4. The price of a colony of bees in a ten-frame hive will vary according to the season. In the early part of the year, in the spring, they are worth a great deal more than they are later on after the honey-flow is over. You can buy common bees, hybrids or common blacks, of the farmers, in box hives, for a very small sum of money. The bees

must be transferred and put into modern hives. After that they should be Italianized in order to bring them up to the standard of the bees sold by supply-dealers. Taking it all in all, cheap black bees are not very cheap in the end. Such colonies as you describe, if of good strength, should be worth about \$5.00. If nice Italians, \$10.00 to \$12.00.

5. From your general description here it is evident that the queen had what is called the "cramps." Very often a queen, if she has been handled or injured, or struck by a frame in removing it from the hive, will appear as if she were dead, and it will be some minutes before she recovers. The bees will hover around her, feed her some, and in the course of a few minutes she will be as lively as ever. We do not know just what is the difficulty; but we have always called it the cramps.

6. Our experience is that beet sugar is practically as good as cane sugar for feeding bees. We never make any distinction. We buy this sugar just as it is on the market, and we suppose a good percentage of it is beet sugar. No chemist is able to detect any difference, and we doubt if there is any.

7. Yes, we consider the metal-spaced Hoffman frames as very much superior to the ordinary wooden Hoffman frames. They are easier to handle, and are stronger.

8. Dr. Miller's main reason for not painting his hives is on the ground of economy. He said the hives will last as long as he can ever use them without the paint, and he doesn't see any reason why he should go to the extra expense of painting; but most beekeepers do not agree with him in this.—ED.]

A One-inch Hole Punched in the Upper Part of the Foundation to Give a Passageway to all the Combs

When I put brood foundation in wired frames I punch a hole one inch in diameter under the top wire. This gives the bees access to all the combs. Otherwise they would be compelled to go over the top-bar, under the frames, or around the sides of the frames, for their stores. It also gives the queen the same opportunity in brood-rearing. I have lost many colonies in years past when there was an abundance of honey in their hives, and I find the above plan is all right.

Conesus, N. Y., Jan. 8.

D. W. TRESCOTT.

[Holes left this way in the combs would be filled up with drone-cells and honey after a good honey-flow. Years ago it was the practice on the part of a few beekeepers to insert a tin tube about ½ inch in diameter in the center and near the top of the combs. The tube would not be as likely to be filled with comb as a similar hole without the tube.

It was thought at one time to be a good practice to cut holes in brood combs at the approach of winter; but it has been abandoned by almost all beekeepers, so far as we know, and in its stead has come the Hill device, or a space over the top of the brood combs, enabling the bees to pass back and forth over the top instead of through the combs. For the Langstroth frame, space on top is preferable to unsightly holes that do little or no good to the combs.—ED.]

Can the Doolittle System of Producing Comb Honey be Used in a Locality where there is no Late Flow?

I received a copy of "A Year's Work in an Out-apiary," by Doolittle. The plan looks good to me, as I am a farmer beekeeper with about 20 colonies and the minimum time to give them; but I do not have the extra frames of combs he uses at fruit

bloom. Could I use full sheets of foundation? and what would be my chances for success by using it?

Sometimes fruit bloom does not yield much nectar with us. Would it help matters to feed thin syrup, as per the Alexander plan? or do you consider the "millions of honey at our house" sufficient? Any other suggestions you will give would be thankfully received.

Auburn, Ind.

W. J. CARNAHAN.

[The Doolittle system of producing comb honey is more practicable in a locality where there is a late honey-flow. If you do not have such a flow you could not very well use it to advantage. It would not be practical to feed as you suggest, because a good deal of the honey in these combs that are held over from the previous season would go up into the sections; and, of course, ordinary syrup could not be used in that way without getting the producer in trouble with the State and national pure-food inspectors. You can, however, carry out the general principle by feeding the colonies up very strong the year previous, so that they have plenty of stores; but the plan of putting an extra set of combs filled with syrup over the top of the colony to make them "rich in stores" will not work, provided it is sugar syrup for the reason already mentioned.—ED.]

Feeding Soft A Sugar on Plates Made of Wire Cloth

Why so much discussion about feeding soft A sugar to bees in the cellar? If the colony is small the paper pie-plate can be used without fear that the condensed moisture will do any great harm. I take the covers off my hives when I put them in the cellar, and place a burlap sack over the hive. Now, I believe I can feed the bees by placing the sugar in plates made of window-screen (wire), and placing the dish over the tops of the frames and covering all with one or two sacks according to the strength of the colony. The bees can cluster under the sugar, and take it up without exposing themselves in any way.

Interlaken, N. Y., Feb. 17. JOHN T. GREENE.

[We believe it to be perfectly feasible to feed soft A sugar on wire-cloth trays or plates; but we wish to make the suggestion that the black wire cloth be used rather than that painted with green paint, as the latter would be poisonous. Where it is not practical to use the wire cloth the paper pie-plates can be used. The sugar should be placed in the plates, and then there should be a couple of cross-cleats placed over the top of the plates, so that, when the packing material is placed down over, the bees will be able to get at the food.

Mr. A. C. Miller expressed the fear in our columns recently that a paper pie-plate would become soaked with moisture and be utterly useless. We do not find this to be the case. Notwithstanding that, in some of our colonies, there is considerable dampness, the plates hold their shape perfectly.—ED.]

Feeding Soft Sugar in Paper Pie-plates to Bees

I went over my bees yesterday, and found two swarms low in stores. I took a paper pie-plate and cut slits in the bottom and set this on top of the frames. I cut slits in the bottom to allow the bees free access to the same. I then filled this pie-plate with soft A sugar, and pressed another pie-plate down over it, bottom side up of course. Over this I put a newspaper and then the chaff-bag. I treated two colonies in this way. I believe this sugar packed in this way will stay in shape as well as candy will. Certainly it will after absorbing moisture from the bees. If this moisture soaks up the plate so as to make it soft and pulpy, it will be all the better

for the bees. The plate will then have served its purpose, and will be easily gnawed away by the bees. When this sugar is gone I will repeat the operation with new plates. Two plates put together this way will hold one pound of sugar. If you would like to know how this scheme works out I shall take pleasure in giving you an accurate account of it.

Stillwater, N. Y., Feb. 9. ROBT W. SCOTT.

[We believe the plan of using paper pie-plates as outlined here by our correspondent to be a good one, although if there is a slit or slits in the bottom of the plate it might be better to use something like ordinary queen-cage candy, made by mixing powdered sugar and honey into a stiff dough. We shall be glad to have our correspondent tell us of the success of this method of feeding this coming spring.—ED.]

Feeding Soft Moist Sugar Direct; who First Used it?

Referring to GLEANINGS, Feb. 1, p. 81, Mr. A. C. Miller says he thinks that the credit of feeding sugar to colonies of bees should be given to Samuel Simmins. I may say that I was visiting an uncle at Withersfield, Suffolk, England, in 1852 or '3, and he had bees in straw skeps. I remember seeing him feed them sugar (then called brown or moist sugar). He fed them in a tube made of the common alder wood with the pith removed and the top split out so it was in the shape of an inverted horseshoe, and inserted it in the entrance at the back of the hives. I do not know, but would suppose that feeding moist sugar to bees was a common practice in England 60 years back, as at that time I was 10 years old; and if all is well I shall be 70 next April; but I remember this circumstance.

St. Louis, Mo., Feb. 10. CHAS. W. COLLETT.

[The feeding of brown sugar or moist sugar to bees is a very old idea; but whether any one, however, has ever fed a coffee A sugar before that recommended by Mr. Simmins we do not know.—ED.]

Wiring, and Alfalfa in Ontario; Timber for Hives

1. Is it practicable to do the wiring when nailing frames together in winter, and put in the foundation as needed?

2. Is alfalfa considered of any value as a honey-yielder in Old Ontario? It is no good in New Ontario.

3. What is the objection to spruce and poplar lumber for hives?

Slate River, Ont., Can., Jan. 22. J. M. MUNRO.

[1. It is the usual custom to nail or put together frames during the winter time, wire them, and put in the foundation at the same time. We see no reason why you should put in the foundation only as fast as you need it. If you have it in stock it should all be put in at one time. During the busy rush of the season you can not afford to take the time to put foundation on the wires.

2. In most of the territory east of the Mississippi River, alfalfa does not yield honey to any considerable extent. We are not able to give you any opinion concerning its relative honey value in Old and New Ontario.

3. Spruce is a very good lumber, but rather narrow, and rather too tough and hard for the purpose of making hives. Poplar is too much inclined to warp and twist. There is no timber in the world that is altogether the equal of ordinary white pine, such as is found in Michigan and Canada. The redwood of California makes a very excellent substitute, however; but it has the objection that it splits very readily, and is not suitable for making the inside fixthres; but it will stand the weather much better than pine.—ED.]

Poisonous Spray During the Blooming Season Injurious to Trees as well as to Bees

I was invited to make an address at the State horticultural meeting of Missouri, held in 1906 at Moberly; and while at that meeting I had the endorsement of some of the very best horticulturists present, that to spray with poisonous ingredients during blooming time would destroy the prospect for fruit on trees so sprayed. Mr. J. C. Evans, who had been the president of the society for more than 20 years, and a man of very large orchard interest and experience in spraying, stated that he had tried it most thoroughly during the blooming period, and he was entirely satisfied that it would kill the prospects for fruit.

One man having extensive orchard interests had sent in a paper to be read at that meeting, and in it stated that he did not know any reason why he should not spray during blooming time, as he considered his orchard interests worth more than all the bees around him, but also stated in his paper that he had sprayed during blooming time; but for some reason to him unknown his trees had set but very little fruit.

Mexico, Mo., Mar. 22.

J. W. ROUSE.

Fruit-men Borrow Bees to Place in their Orchards During the Blooming Season

I am located right in the middle of the peach region; and at first, when the tree-spraying began, I had some trouble, and had to distribute some of your free literature about spraying to show the fruit-men their folly.

It may be interesting to you to learn that now the fruit-growers so value the bees in connection with the fruit-bloom that they borrow my bees, and carry them to their orchards, and bring them back when the bloom is over.

The spraying of peach trees is done just before the blossoms begin to swell to any size—about two or three weeks before opening; but in case they fail to get it done at the right time they prefer to put it off rather than to do it when the trees are in bloom.

Port Clinton, Mar. 28.

JULIUS JOHANNSEN.

Bees Brought Pear Blight

If you see the fool-killer, send him out here. The ranchers sprayed their trees with a strong solution of arsenate of lead for codling moth, and it burned the tender twigs where they used high pressure on the blooms before the petals had dropped off, and the wise fruit inspector told them it was "pear blight" packed there by the bees during bloom. His argument was convincing, for there was the dead bloom; also the dead limb.

Walla Walla, Wash.

C. A. MCCARTY.

How to Color Queens Red

As to your question in GLEANINGS, Jan. 1, 1913, under Stray Straws, regarding the marking of a queen red so that the coloring won't come off within six years, I can tell how it is done in my native country, Switzerland. I don't know, however, from what the coloring matter is made. It can be bought out there by nearly every queen-breeder or supply dealer. It is a fast-drying varnish. Before using it, stir it well. It should not be too thick nor too thin. Otherwise it will not stay on, and will spread. Put the queen under one of those marking-nets made of mosquito-netting, or from an old veil, to keep her quiet. Put a little of the coloring matter on a small sharp wooden stick, and rub it lightly on the back of the queen's breast where it will dry quickly. Then remove the netting.

Highland, Ill., Jan. 6.

XAVIER WIDMER.

Heating Honey Before it Granulates

There is an article in the *Review* for January, by Virgil Sires, North Yakima, Wash., on his process of heating honey as it leaves the extractor, and wherein he claims that honey heated then will keep liquid longer than when allowed to candy first. Now, this is vital to our business. I should like to see the matter discussed in GLEANINGS. Who else so believes and does it? Who knows it is true? Who has a process to heat honey just right to keep clear, and not materially impair the flavor?

Utica, Ill., Jan. 31.

A. MOTTAZ.

[Occasionally, when granulated honey is liquefied, certain parts of the honey are not reduced entirely to the liquid form, owing to the distribution of heat having been faulty. This possibly accounts for the belief that honey which has been heated before it granulates remains liquid longer than if it is heated after granulation, for it is a well-known fact that, if the honey is not entirely liquefied—that is, if there is any portion of it still somewhat cloudy, owing to minute crystals, that honey will granulate again in a very short time; whereas if all traces of crystallization were removed, further granulation would be postponed a much longer time. We do not know that this accounts for the belief expressed by Mr. Sires, but offer it merely as a suggestion. In this connection see the statement by V. V. Dexter, p. 219.—Ed.]

One who Does Not Like Autos

I am glad you issued your automobile number on April 1, 1912. It was the biggest April-fool number I ever saw, and I have taken GLEANINGS for years. I believe you believe in temperance. So do I. I believe you do all you can to fight the liquor traffic. So do I. But I want to tell you that the autos and motor-cycles are a worse curse to the rural population than the liquor-traffic. Some people tell us the auto has come to stay. I tell them that the Devil has come to stay too, and that the day is coming when the Devil and the autos and a good many people who own them and run them will all be in one place, and they will be there to stay.

St. Anns, Ont., Feb. 4.

HERBERT FREAS.

[You have a perfect right to your opinion in regard to automobiles; but there are hundreds of beekeepers in this country alone who own them, and who would hardly know how to get along without them now. The day has passed when automobiles, at least those which are moderate in price, and which are used for business as well as pleasure, are considered only as expensive luxuries.

In regard to the April-fool number of last year that you refer to, we received one other letter from a beekeeper who did not like that number. Since its appearance, however, we have received so many letters of appreciation from others of our readers that we have kept no record of them. We can not expect to please all of our readers all of the time. We know that for a time last year there was scarcely a day that did not bring one or more letters of appreciation for that automobile number, and requests for another one this year.—Ed.]

A Side-hill Facing East for Bees

I have had no experience, but think my present location suitable. It is on a side-hill facing east—rocky ground, and somewhat wooded. Will you advise me as to the suitability of the location?

Mt. Hope, N. Y.

WM. EDWARDS.

[The location, apparently, would be a good one. We prefer to have the bees screened from the prevailing winds; and it is also a good idea to have the apiary or the hives located in some low shrubbery, both for the purpose of shade and to protect the bees against heavy blasts of wind. This is very important in the matter of wintering.—Ed.]

Our Homes

A. I. ROOT

(A sequel to the *Home papers* of Feb. 1.)

Go ye into all the world and preach the gospel to every creature.—MARK 16:15.

But seek ye first the kingdom of God and his righteousness, and all these things shall be added unto you.—MATTHEW 6:33.

O thou of little faith! wherefore didst thou doubt? —MATTHEW 14:31.

I have been reminded that in my *Home paper* of February 1 I omitted, or touched on very lightly, one great reason why the circulation of *GLEANINGS* was increased so rapidly at the start. By request I will briefly go over the points I omitted. Just a few days after I came out publicly for Christ Jesus, our good pastor, the Rev. A. T. Reed, came into my store one day and said something like this: "Mr. Root, there is to be a missionary meeting next Sunday evening, and I want you to take charge and talk to the people." I replied to my good friend (for *then* I was ready to do almost any thing in the world for him) that I was sorry to say I had very little acquaintance with missionary work; furthermore, that I had very little sympathy for or interest in it. He, however, said he would lend me a book about the Sandwich Islands, and I could read the book between then and Sunday, and then he was sure I could give them a talk on it. I again protested gently, saying that the subject of missionary work had always been exceedingly dry and uninteresting to me; and if there was any thing in particular that made me feel sleepy it was a talk about the *Sandwich Islands*. He laughed, and (I think) replied that perhaps I would see things *now* in a light different from what I had formerly. I have forgotten now the title of the book, but it was a history of the work of the Rev. Mr. Gulick, one of the early missionaries to the Sandwich Islands. As I was a very busy man at that period of my life, not only through the day time but often well along into the night I was wondering how I should get time to read that book before Sunday night came. However, I carried the book home and laughingly told Mrs. Root that I had promised to read it during the week. I looked over in the back part to see how many pages there were, divided up, and said something like this: "Sue, I shall have to read so many pages Monday night, so many Tuesday night, and so on until I get up to Saturday night." Accordingly on Monday night I arranged my work so as to get home a little earlier, and went for the book to read the allotted portion laid out. When it came bedtime Mrs. Root suggested that it was time to go to bed; but I replied

that I rather *liked* the book, after all, and did not want to go just yet. Pretty soon, said she, "Why, you have gone away past the part you had marked out to read Monday night. Hadn't you better come to bed?"

I think it was well on toward midnight before I was contented to let the book drop; and I had not only read it through long before Sunday night came, but read parts of it again and again. It was not only a revelation to me, but a *wonderful* revelation, as to what missionaries had done in the way of opening up business in foreign lands and the islands of the sea, aside from the work of converting savages and cannibals and teaching the gospel.

As it was pretty well known in our community at the time that I had been heretofore more or less in sympathy with skepticism and infidelity, quite a turnout to my talk that evening was the consequence. I not only occupied an hour talking about the Sandwich Islands and missionary work all over the world, but I hadn't got half through with my story when the hour was up. The result was, the prophecy of my good mother came at least partly true at this time of my life. I not only hunted up every thing I could get hold of in regard to the foreign mission work throughout the world, but I talked with friends who had relatives in foreign lands, and finally got so full of the idea of "spreading the gospel" that I announced in the next issue of our then very young (and small) bee journal that, if the friends who had relatives or acquaintances in missionary work in foreign lands would send me their names and addresses I would send them our little monthly, *GLEANINGS IN BEE CULTURE*, free of charge for as long as they cared to read it. Now, here came one of my first "happy surprises." I was so little posted in regard to foreign missions that I did not suppose there were more than a dozen or two all over the face of the earth, including the islands of the sea; but when applications came from far and near, and letters of sympathy with the work I had undertaken, I was greatly surprised. One of our faithful clerks remarked to me about this time (the one who opened the mail), "Mr. Root, I fear you have been a little reckless. There are not only many more missionaries in the world than you supposed, but the postage on most of the journals will be twenty-four cents a year, and on some of them forty-eight cents a year. Hadn't you better recall your offer in the next issue?"

My reply was something like this:

"My good friend, don't worry about the number of GLEANINGS that are going at our expense to foreign missions. The great Father above will furnish the stamps, I am sure."

In a little time we had kind letters from almost every part of the world, and these good friends told me about the bees and bee culture in their locality. I distinctly remember one missionary who said something like this: "Mr. Root, your little bee journal has been a Godsend to me and the natives here. I had been for some time past praying and studying over the matter of how I should find something to enlist their interest and attention so I could get better in touch with them. By the directions contained in your little journal I succeeded in making a movable-frame hive; had captured some bees, and finally announced to the natives that I would take a hive all to pieces and show them the work of the bees, and point out the queen, etc."

"Now, this little object lesson proved to be more entertaining and instructive than any thing else I had ever been able to get hold of, brought from civilization. May God speed you in your good work."

From that time to this we have had more or less pleasant relations with missionaries and the missionary work in foreign lands. The great Father above *has* furnished the "postage stamps;" and not only that, he has opened up trade and commerce in hives and hive fixtures all over the world in a way that could not have been done otherwise. In fact, orders came right along from foreign countries in languages that we know so little about that we have an interpreter in New York, besides a pretty fair interpreter here in our own office, to read and translate orders from foreign lands in different languages spoken throughout the world.

Another of the texts that I have given above has been abundantly verified: "Seek ye first the kingdom of God and his righteousness, and all these things shall be added unto you."

Now let me pause a minute to ask you what the consequences would have been had I, as so many of us often do, refused to accede to the request of my good pastor. Somebody asks you to teach a class in Sunday-school or to take charge of a Bible class, or to lead a prayer meeting or something of that sort. You (or *we*) forgetting the abundant Bible promises, make the excuse that we are not posted, or we are not adapted for that class of work, or perhaps that we are not "built that way," so neg-

lect the opportunity. How much should I have lost if I had assured dear brother Reed that I was *totally incompetent* (which was true) to lead a missionary meeting, instead of taking the book, as he requested, and looking into it with eyes that were *no longer blind* to the words that God has sent us. The injunction to go into all the world and preach the gospel seems to me to belong not only to *ministers* but to every creature who has found "the Lamb of God who taketh away the sin of the world." The responsibility rests upon our shoulders to redeem the world, not only from cannibalism and other sins, but to redeem *our own nation* from the dangers that are coming to beset more and more its people.

Not only is our journal now going regularly to every spot on the earth where missionary work is going on, but it is taken regularly by great numbers of people who do not speak our language at all, and many of them can not read it at all.* They look at the pictures and hunt up somebody who is conversant with our language, and capable of giving them some kind of interpretation, and in this way keep in touch with your humble servant and what he has to say in these Home papers.

May God bless this little story, and help many another brother and sister to heed that closing little text, "O ye of little faith! wherefore didst thou doubt?"

* One of the pleasantest acquaintances of my life was a young man in Cuba who knew as little of English as I knew of Spanish; yet we had the A B C book and also took GLEANINGS. We went off on a trip, and were alone together the greater part of the day except the A B C, which he carried along. How we did laugh and "chatter"! The Holy Spirit, which filled both our hearts (for he was a young convert), bridged over the lack of a language common to both of us.

THE VOICE OF THE PEOPLE TRIUMPHANT OVER THE PRESIDENT'S VETO.

We clip the following from the front page of that godly paper, *The Union Signal*:

GREATEST NATIONAL PROHIBITION VICTORY EVER WON.

The veto of President Taft of the Kenyon-Webb bill has been overridden by both houses of Congress. On February 28, the Senate, by a vote of 63 to 21, repassed the measure, and, on March 1, the House of Representatives, by a vote of 244 to 95, took similar action.

When the news came of the victory I said, "May God be praised for having heard and answered our prayers;" but the following from that same front page of *The Union Signal* expresses my feelings so much better I give it also:

I thank God I have lived to see the day when the representatives of the American people will answer

on the roll call with their votes, the entreaties and imploring prayers of millions of country-serving, God-fearing, home-loving men and women. This day, O men, we who hold high station can dedicate one vote to liberty, country, God, and home, and rededicate the Constitution to the people, and withdraw it for ever as a bulwark for that conglomeration of cormorants whod ebauch manhood, slaughter womanhood, butcher childhood, and crucify baby-

hood on 'he cross of alcohol.—*Representative Roddenberry, of Georgia.*

God grant this may be only the beginning of "overriding" the voice of one man who happens to fill a great office; and may it prove a lesson and a check on these same "great men" who presume to ignore the demands of righteousness.

High-pressure Gardening

Whatsoever a man soweth, that shall be also reap.
—GAL. 6:7.

Dear friends, I believe that Mrs. Root has never given any thing, at least direct, to the columns of GLEANINGS; but I am going to give something that I got very straight from her just a short time ago. You may be a little surprised to know that her first talk is going to be on "high-pressure gardening." It came about in this way: A few days ago she went over to visit our near neighbors, Mr. Keller's people. Mr. Keller had just harvested a very fine crop of celery, and in going up to their home she passed very near the celery-field that had lately been cleared off. She noticed on the way quite a number of large fine stalks of a dark-green kind of celery that seemed to have been skipped and left standing in the field. When she got into the house, one of the first things was to inquire why these great beautiful roots of celery were left when the rest was all taken away. Mrs. Keller informed her that they were a sort of sport that didn't bleach out like the rest; and, as a rule, they were not worth taking care of, and so were allowed to stand in the field and go to waste. She said, furthermore, there had been considerable trouble in getting seed that would produce new French Golden Self-blanching celery without any sport or admixture of this dark green and comparatively worthless sort. In fact, one man, I think he was a newcomer, or, at least, new to the celery business, procured some seed that he supposed was all right, and planted several acres; but when it came harvest time so much of it was of this green variety that the crop was practically worthless—not worth harvesting, in fact. The poor fellow put up with his disappointment the best he could, cleared off his celery, and planted tomatoes. This, of course, was a year ago. When his tomatoes came to bear they were little bits of things, not larger than walnuts, and, in fact, he secured nothing, or practically nothing, worth harvesting in his whole field of tomatoes of several acres. As he had procured his celery seed and tomato seed of one and the same firm he ap-

plied to them for redress from his expensive loss. They, however, disclaimed all responsibility, and referred him to the clause in their catalog as follows:

While we exercise great care to have all seeds, bulbs, and plants pure and reliable, we do not give any warranty, express or implied. If the purchaser does not accept the goods on these terms and conditions, they must be returned at once, and the money that has been paid for the same will be returned. We can not afford knowingly to sell seeds doubtful as to vitality or purity. We test our seeds before sending out, and should they prove defective in germination or purity when properly planted and cultivated we will refill the order free or refund the price paid.

When she told me about it, I said, "Oh! that man wasn't posted." He ought not to have undertaken it—at least, he ought not to have undertaken to grow celery by the acre without having more practical experience. He should have purchased his celery seed the year before he wanted to use it, and then planted a small area, and, if the seed grew satisfactorily, use the same seed to grow his plants the next year, and the same with tomato seeds. He shouldn't have thought of setting tomato-plants by the acre until the seed had been thoroughly tested the year previous, and until he *knew* it was exactly what he wanted.

I gave her this advice thinking that I was able to supply a great amount of wisdom, and that, if they had only applied to me, how much could have been saved.

After dictating the foregoing I concluded that I had better go over and see my good neighbor Rood, who has several acres of beautiful celery almost ready for market, and his celery seems to be comparatively free from these worthless sports of green stalks. Now, just listen.

Practically speaking, it is true that "whatsoever a man soweth, that also he may reap;" but Mr. Rood, I am very glad to say, was able to give me a piece of information that makes it possible to grow a crop very much *better* than the seed which was sown. So it isn't always true that "whatsoever a man soweth he shall surely reap." Now, while giving you this great secret in regard to growing celery, and perhaps many other crops, I am going to illus-

trate another point that I have long had in mind; and that is, that people coming down here from the North, and thinking that they can help out in the garden or fields, and earn fair wages—say wages comparing favorably with our expert colored men—such people are usually greatly mistaken in their estimate of their own powers. Now, here is the important feature. First, get the very best seed you can buy. Mr. Rood has been buying seed from several great seedsmen of the North for years; and, as a rule, when he pays the price for their very best seed—say \$15 or \$20 a pound for the kind of celery seed that is sown here in Florida—he is pretty sure of a fair grade of seed. I asked him if he had any objections to my giving the names of the seedsmen who furnished him his seed. He replied something like this: “Mr. Root, the man or seedsman who furnished me the best celery seed a year ago may not be able to furnish some equally good this year, and *vice versa*; but I will tell you what we do. When the little plants in the seed-bed have got big enough to distinguish clearly between the true and the green or worthless plants, we have expert colored men go through the seed-beds and weed out all of these objectionable plants. In that way, even if our seed is comparatively bad we can get almost a perfect stand of the genuine French Golden Self-blanching celery.

Now, here comes in the point I am speaking of. A year ago a white man came down from the North and applied for work in the gardens. He supposed, of course, that he could do any thing that the colored men did about as well as and perhaps a little better than what they did. So Mr. Rood set him to work, after explaining carefully what was to be done in weeding out the objectionable celery-plants. The man worked, I believe, one day or a part of a day, and perhaps was disappointed in regard to the amount of pay he received. Mr. Rood said he would have saved fully \$10.00 if he had let the experienced colored men stick to their job instead of giving this man a chance to work in the garden even a part of a day. Therefore, take great care, not only in regard to the seed you sow, but in regard to the plants you set out in the field *after* they are grown in the seed-bed.

Most of the celery seed used in this region is imported from France. I asked Mr. Rood if it wasn't possible for us to grow as good seed here in America as they get imported. He said that so far it didn't seem possible to get as good seed grown here, although California has given us some celery seed that compares well with the best

French imported. Since then I notice our new seed catalogs advertise California seed, and declare it is as free as any of the French from the worthless green sports.

Since dictating the above I have interviewed my neighbor, Mr. Keller. Let me explain a little. Mr. Keller had not been as successful a celery-grower as my neighbor Rood and some others. During the past summer, however, he spent quite a little time and money in getting proper tiles and thoroughly underdraining his piece of about two acres; and the result is, he has had very much better success than he has ever had heretofore. Even our Florida sand needs thorough underdraining to get the best results, especially after such an extremely wet season as we had in 1912. Well, he sold his celery for \$2.40 a box. As nearly as we could figure it, he got about \$1200 for the celery on a single acre; but I suggested that he had to pay freight out of this, and he said, “Not at all.” A New York man came and looked at his celery, and made him an offer and paid him spot cash right there on the ground at \$2.40 a box. When I asked about the fertilizer, he said that the fertilizer cost him perhaps a little over \$100 an acre. But what does this amount to when the crop is sold right on the ground for \$1200?

My neighbor Rood is just now harvesting the finest crop of celery he ever grew. He, also, most thoroughly underdrained his land before he commenced growing celery; and the quality of his celery is considerably ahead of that of neighbor Keller, and he probably gets better prices than those mentioned. He said that he applied about three tons per acre of a fertilizer that cost about \$40.00 a ton; but I think some of his land would give a yield of very close to \$2000 per acre.

Let me digress right here to answer a great number of inquiries as to how much a man can make to come down here and grow celery, grapefruit, etc. Now, I can't answer such questions. And I might safely say the man who asks it will rarely be able to make any great result. It takes a practiced expert to grow celery; and I think likely it takes a practical expert to grow grapefruit also; and these men who have learned the knack usually make a good thing of it year after year; but it doesn't follow at all that a green hand, or somebody who has failed in almost every thing else, can come down here and “get rich” growing stuff in Florida. Let me give you an illustration.

Another neighbor, who is fairly successful with truck gardening, last year did so

poorly in growing celery that he started this year to give it up, and he has been working out by the day at painting, his regular trade. As a consequence of the terrible freeze in California this year, celery, oranges, grapefruit, and many other things are "way up" in price. If this neighbor of mine, who became discouraged, and gave it up, had kept right on growing celery he would be out of debt now, and perhaps had money in the bank. You can see from this that the successful gardener must take the seasons, conditions, etc., as they come. Sometimes he hits it just right, and again he doesn't; and the proper way for him is to keep right on at his chosen occupation, and he will eventually succeed.

Just a word more in regard to this choice celery seed. I see this seed quoted in the catalogs all the way from 15 to 25 dollars per pound; and very likely the best is the cheapest. What does the cost of the seed amount to when the crop sells for something like between one and two thousand dollars per acre?

SOMETHING ABOUT APPLES.

My first package by parcel post was three enormous and delicious apples, sent by Stark Bros. Nurseries and Orchard Co., Louisiana, Mo., by the request of our good friend S. W. Morrison.

I asked Stark Brothers to send you specimens of Stark's Delicious. I have eaten them for four years and pronounce it the best winter apple in the world; good from Feb. 1 to April 1.

Oxford, Col., Jan. 20. DR. S. W. MORRISON.

There were three apples in the package sent by Mr. M., of immense size, and they are certainly "delicious"—at least the one I sampled was. If there was any fault with it, perhaps it was rather too much on the sweet order for my taste. Stark Bros. tell us that the tree is a very thrifty grower, and bears at an unusually early age. The apples came to me just a little after New Year's day; and in order to test their keeping I am holding two of them yet. Although we have had the warmest spell, perhaps, during the month of January here in Florida for years past, the two remaining apples are keeping, up to this date, Mar. 3, in perfect order, while other good apples in the same box all decay. It seems to me if all that is said in regard to this most beautiful and luscious apple is true it certainly is an acquisition indeed. We may well call it one of God's new and greatest gifts to the children of men. The apple is so large that one of them makes a large "supper" indeed for myself. The trees are offered at the very reasonable price of only 40 cts. each by the single tree. When they are ordered by the

tens or hundreds the price is quite reasonable indeed. We are hoping that parcel post may do great things in the way of furnishing an apple-loving people with an abundance of apples at a reasonable price, making a short cut from the producer, where apples are often allowed to go to waste because there is no paying market for them, to the consumer, and especially the children. The *Rural New-Yorker* has been for years talking about more apples and better apples for the health of our people, and I believe they have started what has been called the "Apple Consumers' League." May God be praised for our beautiful luscious and health-giving apples that now ought to be in great plenty all over the face of the earth. Especially let us try to make it possible for the growing children to have all the apples they care for, without stint and without extravagant price.

Here is something additional in regard to the Delicious apple, clipped from the *Rural New-Yorker*:

Next to the King David stood a tree of the Delicious, of the same age, and it bore just two specimens. This is no great disparagement, however, for I know the Delicious to be a heavy bearer, and the tree is beautiful in its vigorous growth, with clean bark and strong shapely top. A friend who has several trees tells me that they are regular bearers, and that he has customers who make him special offers of \$6.00 per barrel for their private family use. So far as I can learn the Delicious will take its place as a permanent addition to our standard lists, though the assertion that its quality is unexcelled by any other apple requires modifying. I have seen people of cultured taste who, when not told the variety they were testing give it second place to Stayman Wine-sap. Both kinds were fine specimens from Pacific-slope orchards.

DASHEEN AT BROOKSVILLE, FLA.; FROM BROOKS-VILLE BOARD OF TRADE.

Mr. A. I. Root:—Your favor of February 1 to Mrs. R. J. Crather, of this place, has been referred to the undersigned for answer, and in reply thereto I will say that we take great pleasure in giving you some data concerning what we regard as the most remarkable root vegetable in this country.

About eight years ago the Department of Agriculture, Washington, D. C., began experiments in propagating the dasheen. They had discovered it in Japan, where it was considered more popular than either the Irish or sweet potato. The Japanese had imported it from Trinidad Island, north of South America; and, although they had never propagated it to any great extent, yet the best families of Japan were cultivating it in patches not more than fifteen feet square.

When the experts of the Department of Agriculture discovered that the dasheen contains about ten per cent more starch, and from fifty to seventy per cent more protein than the potato, they concluded that it was worth trying. Some of the tubers were brought to Washington and propagated under hot-house methods, where the results were favorable, and the tuber was then given a trial in various States, including Maryland, North Carolina, South Carolina, and others, and northern Florida, but without satisfactory results, as they could not make a good tuber.

The department was about to abandon the propagation of dasheens when Dr. Hood, of Orange City, Fla., suggested that the dasheen be given a trial in the *Brooksville* hammock-land district. That was three years ago. They began here on the government farm with twenty-four varieties secured from Japan, Trinidad Island, Porto Rico, and Cuba. The results were more than satisfactory. The second year, by advertising in many foreign countries they increased the number of varieties to fifty-eight, and this year they had *one hundred and seventy-four*. Out of all these the department found five or six varieties which they considered of especial value as human food.

This year they had seven acres planted in dasheens, that had been tested for two years, and the yield was over *3500 bushels*. The Department distributed the edible sizes to various hotels in the North and East, and the seed sizes all over the southern States, so as to give everybody a chance to try them; but we do not expect favorable results from any locality outside of southern Florida, and that, too, on heavy hammock land. In northern Florida and States north, the seasons are too short, as it requires about eight months for the dasheen to mature.

The tests made here in both hammock and pine land show that the hammock land yields from 500 to 800 bushels per acre, while on pine land the tuber can not be raised on a commercial basis at all. The Department, therefore, has made arrangements to have quite a large acreage planted here this year so as to be able to take care of the demands for next winter.

As to the qualities of dasheens, they are most remarkable. After being planted they do not come through the ground for about three weeks; but if banked up with sand when they come up, they can be blanched the same as celery, and will grow from twelve to fourteen inches high *in as many days*. Remove the sand and cut the tender tips, and they may be used instead of asparagus tips or mushrooms. This product has been tested at the New Willard hotel, Washington, the chef of which declares that they are superior to either asparagus tips or mushrooms. It will make eight growths of this kind every season—one growth every twelve days. After the last cutting for this purpose, and the tips get to be from three to four feet tall, the stalks can be used instead of rhubarb or pie plant for pie-filler, and are better than rhubarb in the absence of any acidity or acidity. Certain varieties may be grown for greens which may be made from the leaves minus the ribs.

Now as to the tubers. They may be served in any style that potatoes, either Irish or sweet, may. At the base of the plant is a large tuber called a corm. This corm is too large to be served as an edible on the table, but may be sliced, evaporated, and ground up into flour. Of this flour can be made any thing that can be made of wheat or rye flour, such as bread, doughnuts, cakes, or pie crust; in fact, you can make the crust out of the flour, and make the filling of the pie out of the stalk or the rhubarb.

Dr. Hood, of Orange City, states that, served as pancakes, they are superior in every respect. He has found that persons suffering with indigestion can eat three or four dasheen pancakes, whereas half of one of the other kind of pancakes would cause pain.

The dasheen is very popular in Brooksville and vicinity. A year ago we opened the Varnada hotel with a dasheen banquet. There were one hundred guests present, and every one of them testified that the dasheen was superior to any thing ever eaten in that line. Since then we have had served by Mr. Gomme, superintendent of the government farm here, an entire meal made of dasheens and its various by-products.

Being rich in starch and protein the dasheen may be used for stock feed. In fact, both hogs and cattle will eat the tuber before they will eat any other kind of root vegetable, and they grow fat more rapidly on dasheens than on any other kind of vegetable. If they should never make any thing of the dasheen for human food it would be worth the cost of propagation for cattle and hog feed alone.

The prospects are that we shall have from 35 to 50 acres planted in dasheens this year in Brooksville section; and as the government has released four varieties which they have tested, there will be several parties here with a sufficient amount of dasheens to supply any probable demand the coming year.

You will note that we have indicated a use for every part of the dasheen, stalk and tuber, excepting the ribs of the leaves, which must be removed when they are used for greens; but the department at Washington has discovered that there may be distilled from the leaves a very rare fluid, something like that distilled from the century plant, which is known as "punkha."

From tests being made now, the best chefs of the best hotels in the large cities, and also by several scientific men, we are encouraged to believe that the dasheen has a great future; and it has already replaced the Irish and sweet potato in many homes in this district.

Trusting this information may be of benefit to you, and soliciting your further correspondence in case you desire any further information along this line, we remain

Yours very truly,
BROOKSVILLE BOARD OF TRADE,
per C. H. Freas, Sec.

Brooksville, Fla., Feb. 11.

My dasheens are now coming up, and some of them are putting out the second leaves. They very much resemble, so far, a calla lily, and are now (March 1) growing very rapidly.

MORE ABOUT DASHEEN.

Experiments have been conducted with the dasheen, both in Washington and Brooksville, which demonstrate that it is a most wonderful vegetable, capable of furnishing the raw material for a great variety of dishes. As the new growths come through the ground the stalks may be blanched like celery, and cooked and served as mushrooms and asparagus tips. Later the leaves of certain varieties, minus the ribs, may be served as greens, and the stalks as sauce and pie filling, which are said to be superior to rhubarb for those purposes. Thus the entire stalk and leaf, excepting the ribs, yield food for man; and even the ribs of the plant are not valueless, for from their juices may be distilled a most precious liquor known in local parlance as aroid punch, but to the men of science as something akin to the liquor obtained from the century plant.

Brooksville people have been favored with several packages of Mr. Spawn's evaporated products and his flour, especially the dasheen flour, the raw material of which is produced in Brooksville, and they will welcome the announcement that this place is scheduled to become the home of a plant similar to the one at Kissimmee.

As the experts of the Department of Agriculture, Washington, D. C., are conducting experiments which will determine the relative value of the dasheen as a food product, and since the crop here, comprising eleven acres, is still under their supervision, those who have never participated at a dasheen banquet will be compelled to accept amateur statistics and data on this subject until experts choose to publish the scientific facts.—*Tampa Tribune*.

Poultry Department

FORTY-EIGHT CHICKS FROM FIFTY EGGS IN A FIFTY-EGG INCUBATOR.

Some of the friends in times past have called me a bungler with poultry. I think it was the friend, however, whose scheme or "system" had been exposed. Well, I have been a bungler, and I don't know but I am a bungler somewhat yet; but this morning, this 11th day of February, 1913, I have taken forty-eight good strong chicks from fifty fertile eggs. Now, I might make it a little better than that, I think, when I explain that, in testing the eggs, there was one of the fifty that I threw out as doubtful. Let me tell you how I mark eggs that are doubtful. I just put a cross on the large end. If, after further testing, however, I found these crossed eggs are fertile after all, I put a circle around the cross, and that means the cross reads "naught" or "nothing." You may wonder how I get fifty fertile eggs in a fifty-egg incubator. I do it this way: For the first three days I stand them on the small end. In this way I can get sixty or sixty-one eggs in the average fifty-egg incubator. Of course, during the first three days these eggs can't be rolled around very much, as they stand on the small end. I think I have explained before that in this way I manage to have fifty fertile eggs, as a rule, to fill a fifty-egg incubator. Now, this report doesn't amount to very much unless I can do it again, and can show some of the rest of you how to manage to get equally good hatches. I am not sure that I can do this; but I can tell you briefly how I manage. It comes up like this—to *whom* or *where* does the credit belong? Is it to the man who furnished the incubator, or is it because of the favorable season, or because I have taken pains to have my eggs well and strongly fertilized? or has your humble servant some credit in the matter? I have explained before how I gave two males to my forty-eight laying hens. I told you when I started down to Florida that I was going to use an electric incubator; but when I got here I found out they hadn't got around to giving us a current for the whole twenty-four hours, so the electric incubator couldn't be used until somewhere near the first of February. As I didn't want to lose so much time I sent for one of the \$7.00 fifty-egg incubators made by the Buckeye Incubator Co., of Springfield, Ohio. I have taken out three hatches this winter with this machine before the one that has just now given such excellent results. I followed exactly the directions that came with the machine, with the exception of letting the

chickens all remain in the machine until the 22d day. I removed them just after dinner from the machine on the 21st day. They commenced coming out on the 20th, so that a greater part of them were nearly or quite twenty-four hours old when I took them out of the incubator. My reason for removing them a little sooner is this. Every time I take off a hatch I find a great quantity of fuzzy down, that has rubbed off from the chickens, down among the eggshells in the incubator. Sometimes there will be a good double handful of this down (especially where there is a large hatch) down in the bottom of the incubator. Now, I figure this must be somewhat of a loss, because chickens, especially when taken from the hot incubator, and placed right out almost in the open air, as I do here in Florida, need every bit of their feathery down to protect them from the breeze and the weather. As they seemed quite restless, and evidently in want of more air, I decided to take them out, as I told you, on the afternoon of the 21st day. Well, after taking out forty-four I discovered there were four more that were hardly ready to come out. One of them was just out of the shell, and three more were only partly out. One of the shells was just pipped. I dipped these partly hatched eggs in water about as hot as I could bear it with my hand, and then put them back in the incubator on a wet cloth wrung out. This was to supply what moisture or dampness was lost when the incubator door was opened. Now, I haven't very much faith in helping chickens out of their shells, although in one of my hatches I helped two out that seemed so feeble and in such bad shape that I had no hopes that they would ever live, or amount to any thing if they did live. However, I did the best I could with them, washing off the glue that had dried on to them with hot water, then putting them back in the incubator, and awaiting developments until next morning. The next morning they had improved so greatly that I kept them a little longer, and finally put them out with the rest of the hatch, intending to keep watch and put them back in the incubator if necessary. To my great surprise, however, after twenty-four hours had passed I had great difficulty in finding the two chickens that I helped out of the shells, and since then I have never been able to tell one from another. They are all just alike. This was a thirty-six chick hatch, and they are all alive and well now, just three weeks since they came out of the shell.

Now, as two of the chickens seemed to be

making very slow progress in breaking out of the shell in this last hatch, I struck on a plan that I believe will be a way as to be one of the best, if not *the* best, for chickens that do not succeed in getting out at the time the others do. I simply crush the shells with my fingers in such a way as to crack the outer shell pretty thoroughly. In the course of a few hours I had the pleasure of seeing those chickens out of the shell and on their feet. Some one may suggest that getting chickens hatched and bringing them to maturity is a different thing. But I want to tell you that I haven't lost a chick that I know of this winter, except six that were carried off by hawks before I found out exactly where my chickens were going. The hawk has been fenced out by covering my two small yards for the smallest chickens with three-inch poultry netting, as I have explained. Since then not a chicken has been lost. Every chick that is hatched goes right along without a break.

COUNTING CHICKENS "AFTER" THEY ARE HATCHED.

A good deal has been said about counting your chickens *before* they are hatched; but, so far as I know, not very much about counting them *after* they are hatched. Some of our readers, and perhaps not a few of them, have had some trying experience in trying to count them after they are hatched, and having the count hold out. When I started our convergent poultry-yard I thought I was going to have a "dead open and shut" on keeping my chicks, especially in keeping them free of loss from rats, skunks, coons, etc. I have told you something about the poor fertility of our eggs when I first moved them over to our home. There were two troubles about the fertility. First, most of the hens are just out of the moult, and the rooster himself was going around destitute of tail feathers. Secondly, he had toward fifty hens in his care. One of these hatches at this time gave only sixteen chickens in a fifty-egg incubator. Now, there would not have been even *sixteen* had I not helped two of them out of the shells. These two were such dilapidated-looking specimens that I had very little hope they would live. I put them back in the incubator (mostly because I hated to kill the poor little things), and kept them there twenty-four hours. Then when I put them in the fireless brooder, and they moped around about twenty-four hours more, I felt *sure* they were going to die. However, greatly to my surprise, on the third day they began to pick up, and in less than a week I could not tell which were the ones I hatched from

the others. With these new poultry-yards so well protected with inch-mesh netting I felt sure no rats nor skunks could in any manner interfere with my chickens; and this little brood got on very well until they were about two weeks old, when one day I was obliged to admit that there were only *fifteen* instead of sixteen. Next day there were only fourteen, and so on, until a chicken a day was going *somewhere*. They counted all right at night, and they counted all right next morning; but when night came there would be a chicken missing. Wesley suggested it was a hawk; but I hadn't seen any hawks around, and I was very much puzzled and worried about it. Finally, Wesley caught a hawk right in the act, and made him let the chicken drop. The poor fellow, however, was so badly scared he died a few hours afterward. I finally declared I was going to do something to have a "dead open and shut" on a *hawk* as well as a dead open and shut on the rats and skunks. The question was, how to do it. Neighbor Abbott said he got rid of the hawks by shooting them with a gun. Now, this was a lot of trouble, and I don't like to use guns any way; and, besides that, you must keep on shooting day after day, and year after year. You never can tell when you have got *all* of the hawks. Two or three years ago, when the hawks started I invested in some three-inch-mesh poultry-netting, declaring that I was going to have covered yards for my small chickens, at least until they were old enough to keep out of the way of the hawks. Now, I don't like penning up chickens in small yards. Let me explain a little.

From the next hatch from my fifty-egg incubator, after the one I have mentioned, I secured thirty-six live chicks from fifty eggs. Well, these got along all right until they were about ten days old. Then there was one little bunt chicken that went around, or stood around, with its wings hanging down. You probably have seen them under like circumstances. I tried giving such chicks extra care, bread and milk, etc.; but so far it has been mostly a failure. Now, these thirty-six had been kept inside the brood-house until they were ten days old, because I feared the hawks that had been making such havoc with my other flock. Finally we got to work and covered two little yards overhead with three-inch netting. I think these little yards are about 40 feet square. In this yard that was covered overhead to keep out the hawks I opened the door and let my thirty-six chicks loose. This one with its wings drooping didn't seem inclined to go outdoors. Feel-

ing pretty sure he would die any way, I took and tossed him out.

Well, pretty soon the rest of the thirty-six had unearthed a lot of crickets that were under the dried-up hay and rubbish, chasing each other about the yard to see whom the crickets belonged to. This wakened up my droopy chick, and he got in the run with the rest. By night he was greatly improved. The next day he picked up still more. Now, instead of "going dead," it is a hard matter for me to tell which is the sick one from the rest. This chick, in my opinion, was dying because he didn't have sufficient sunlight and sufficient outdoor exercise, nor, perhaps, the variety of food that chickens need at this age, although we had been giving him chick food, a mash, beef scrap, charcoal, grit, and every thing recommended, at least every thing that is rationally recommended. Now, my opinion is from much careful observation that thousands of chicks are dying continually by too much artificial heat and too little outdoor sunshine and exercise.* My chickens, when ten days old, will chase each other about the yard at a temperature below 50, and it doesn't seem to hurt them a particle.

This covered yard I have mentioned is open on the south side up as high as your head. Of course, there is an inch-mesh fence along the ground, which goes down into the ground to keep out the rats. Above this there are two or three feet where a hawk could easily fly in if he felt so inclined. Well, I left this opening on purpose, hoping some hawk would fly in and couldn't get out, and then I would have him captured and help save some of the neighbors' chickens as well as my own.

Some of you may suggest that it is quite an expense to cover a yard, even if it is only forty feet square. To which I reply it is something of an expense to spend time and money for feed in raising chickens until they are half grown, and letting a hawk carry them off; and not only an expense, but think of the discouraged feeling that comes to one after having taken so much pains and care to nurse chickens through bad weather and then have them carried off in this way. It dampens my spirits and spoils my enthusiasm for the whole chicken business; but when I can succeed in getting things so arranged that every chicken that comes out of the incubator gets to be a big

live useful fowl, then I feel some animation and enthusiasm to go ahead. As yet I have no netting over my yard for young ducks. The hawks seem to have taken no notice of the ducks so far. I have seen in an advertisement of Indian Runner ducks that hawks never molest them. I wonder if this can be true. Speaking about Indian Runner ducks, I have just this morning brought in seventeen eggs from eighteen laying ducks. *You* may have had as good results as this from eighteen chickens, but I certainly never have before. Of course, I haven't had seventeen eggs every day; but they have been running from twelve to fifteen and sixteen for quite a little time. So far the Indian Runner ducks are better layers than any chickens I ever had any thing to do with. In regard to the eggs for table use, after having tested them repeatedly I greatly prefer a boiled duck egg to a boiled hen's egg. They certainly are richer in quality, and there is ever so much *more* in one of these big duck eggs. Let me repeat again, if you want lots of duck eggs, and good-sized ones, you must give them an abundance of feed. Our ducks now have soaked corn right before them, not only all night but all day long. After having taken a swim and a run down the canal, perhaps half a mile or more, they come back toward noon, or perhaps a little after noon, and go for their tub of corn (which is up close to the convergent poultry-yard) as if they really enjoyed the fun. After having had about a dozen dips into this tub of corn, and a drink of water to go with it, they go on a lively run for the canal again. Now, you may say it is quite an expense, especially with the price corn brings down here in Florida, to keep corn before the ducks, letting them take it at their own pleasure; but, as I said in regard to the celery business, what does the cost of a little corn amount to compared with the quantity of eggs I have mentioned, especially when the eggs also bring 30 cents a dozen, and that is what we are getting for them? Four duck eggs will bring ten cents, and I think ten cents will pay for all the corn that the whole flock of twenty-two (that is, including four drakes) consume in twenty-four hours. Of course, I am fortunate in having this canal that they can run to so constantly.

By the way, when I let them out in the morning, after their eggs are laid, I notice that they make a hurried run for the puddles that are left during the night on account of the rising and falling of the tide. Fortunately, the tide, when it is up high, comes clear up on to the canal adjoining my

* I am fully persuaded there are thousands of people just like this chick. They are dying, and don't know it, for lack of outdoor air and sunshine, and *something to do*. Let them wake up, get out and search all outdoors for "God's gifts," then "get busy" distributing these gifts to poor hardworking and poorly paid humanity, and they will promptly *get well* like the droopy chick.

premises. Then when it goes down again there are numerous puddles left in the hollow cavities of the coral rocks. These puddles contain little fish and other salt-water animal life. Just the other morning a duck ran out on the bank with something too large for her to handle. After having tried in vain to break it in two in order to swallow it I discovered that she had quite a good-sized flat fish, something like what they call in the North a sunfish. From this I infer that they get a good many little fishes by going up and down the stream every morning. Now, wherever it is possible to have access to a running stream, especially where the ducks will not annoy or interfere with the neighbors in any way, it certainly is a very desirable place to grow Indian Runner ducks. Where you have such a stream on your own farm or your own premises you are doubly fortunate. I think we may safely include the Indian Runner ducks with another of God's most precious gifts to his children. It certainly furnishes a very healthful form of animal food, and, so far as I can see, at a very reasonable price indeed. I have never heard any complaint from my ducks' eggs as articles of food. It seems to me that the quality is very much better for having the abundance of corn that they do every day. They are really "corn-fed" duck eggs. Our grocers, however, mix the duck eggs right in with the hens' eggs, saying that they have no complaint, and they don't discover any difference. Some of their customers, to my knowledge, pick out the duck eggs on account of their greater size. You certainly get more eggs for your money when duck eggs can be purchased at the same price than where you buy hens' eggs.

I want to say something more about lettuce. Young ducks, if they have access to plenty of head lettuce, will take it very largely in preference to grain, and it is a great saving. Ours are making a most astonishing growth, and a great part of their feed is lettuce from the fields around among our neighbors. Not a duckling has been lost so far, and, so far as my experience goes, I should say that they are easier to raise than chickens.

Just a word about the hawk. When I saw in the poultry journals that a couple of guineas in the poultry would be a great preventive against depredation by hawks, I sent clear up to Pennsylvania for a couple of Pearl guineas. They are just here, and I greatly enjoy watching the queer antics of these strange birds. The guineas are the greatest flyers of any thing I have seen in the line of domestic fowls. They

will rise almost straight up as high as the tree-tops, and do it apparently with the greatest ease. The male bird, the very first morning, gave presuming roosters and hens all to understand in a very few moments that he was "lord of the domain;" but when it was once settled by unanimous consent, he was pleasant and friendly.

"FENCING OFF" THE HAWKS.

It is now Feb. 5, and it seems my plan of leaving a part of the south side of the covered yard partly open did not work, for we found another dead chicken, with a wound under its wing about the size of a half-dollar. Wesley thinks that, after the hawk killed the fowl it was unable to carry it off because it was so big. This is the third one we have found lacerated under the wing in about the same way. Two were in the yard, and one when Wesley made him drop the chicken in the field. We have now enclosed these two yards *on all sides* as well as overhead, and we hope it will end the depredation from hawks. Covered yards—that is, if they are of any size—are rather expensive, it is true; but these yards are necessary only for chicks, say under four or six weeks of age; and, once made, they should last a good many years.

CHUFAS IN NEW YORK STATE, ETC.

Dear Friend Root:—I have noted quite a number of items in GLEANINGS relative to chufas, or earth almonds. I grew many of them in years past while in the poultry business, and know the yield from them is immense. I never measured or estimated the amount grown on my plots, but am positive the yield was very far above 100 bushels per acre. I have counted 600 fine large chufas on a single hill, besides many small ones. I grew the finest chufas on black muck soil. Even when planted close, they made big bulging hills filled with fine nuts. When ripe I would lift the hills with a fork, the roots and nuts staying together in a compact mass. If I wished to save any for seed and other uses I would pulverize the hills, and sift out the dirt and wash the nuts and dry them, which was an easy matter.

Most of the chufas I grew for my poultry, and always believed them marvelous egg-producers. For winter use I would store the hills in a dry place, and every day throw out a lot of the clumps for the hens to work over. It just did one's heart good to see the biddies scratch and dig the hills to pieces, and ravenously devour every nut. It did my heart even more good to see how they would shell out the eggs. Here was exercise and rich hearty food in abundance—the two things most essential for winter laying hens. The cost of harvesting the nuts in this manner for the hens was negligible, and they went very far in the saving of expensive food. It certainly is a wonder that these valuable nuts are not extensively grown by poultry-keepers. I should be pleased to hear from others on the subject.

Hyde Park, N. Y., Dec. 14.

A. T. COOK.

Please send me a copy of Mr. Terry's health book. Don't let me miss a single copy of GLEANINGS. Each copy is a welcome and appreciated volume of love and instruction.

NO. 8

Editorial

OUR COVER PICTURE.

THE view seen on our cover for this issue shows a part of the apiary of August de Malachowski, whose illustrated article appears on another page. In the foreground is shown the old model of the hive "Elita," as it appeared in 1909. The brick tenement hives are also shown, each of which contains four colonies.

"A BATTLE WITH BEES."

AN article under the above heading appears in the December issue of the *Wide World Magazine*. The story was told originally by Mr. Philip J. Baldensperger, an apiarist in the Holy Land, and reported by Frederick Lees. The article is intensely interesting, and any of our readers who have an opportunity to get a copy of this magazine will make no mistake in reading it. The article is illustrated by some beautiful engravings of colonies of bees loaded on camels, of Mr. Baldensperger's apiary, etc.

WHY A LIGHT MOTOR TRUCK FOR OUTYARDS.

WE recently purchased a small motor truck capable of carrying 1000 lbs. to be used in connection with our system of out-apiaries. The reasons we use a comparatively small machine are, low first cost, low upkeep, quick trips, and often. A large truck carrying two or three thousand pounds would be heavy and unwieldy. It would cut deep into meadows and fields where the apiaries are located. A light truck will carry as much aggregate weight in a day or a week, because it will go oftener. This is important, because the men should keep in close touch with the yards. Our general plan is to have a crew of two or three men take care of all the yards. If time is money it is important that these men be transported to their work as quickly as possible. During the height of the season a motor cycle in addition to the truck will carry a man from one yard to another to look after

swarms, cells, or other work of that nature, in a very short time.

We are just now distributing our 600 colonies around in fruit-orchards. The fruit-men are asking us to put bees on their ranches; and, of course, it is to our interest to put them there. Our plans are now to have seven or eight yards—possibly more; and the advantage of a small truck capable of carrying 25 colonies at a time is that it can move the bees at any time to pastures new. In one particular case we expect to move 100 colonies to a fruit-ranch of between sixty and seventy acres of fruit-trees ten miles distant. There is little or no clover in that locality. When the season of fruit-bloom is over it is our intention to move to where much alsike is grown. Four trips will move the whole yard of 100 colonies in less time than it takes to move with a two-horse team, because the distance will be great. Our experience is that a team, driver, and apiarist, will take about a whole day and sometimes into the night to go after a yard of forty colonies eight miles away, and bring them back home and put them in the cellar. That same bunch of forty colonies could easily be moved with a motor truck capable of carrying a thousand pounds on two trips in less than half the time; and, what is more, it is sting-proof.

We have studied this question from a good many different angles; and the more we study it, the more we believe a *light* truck will be much better than a heavy one that will tear up the soil in getting to and from the yard.

A CAUTION ABOUT SENDING HONEY OR PACKAGES OF BEES BY PARCEL POST.

THE ROCKY MOUNTAIN BEE Co., in this issue, asks for information on how to send honey by parcel post. The matter is of such importance that we thought best to give our reply here. While it is perfectly practicable to send eggs, comb honey, and other fragile articles for a short distance, say for rural delivery, we doubt whether it is advisable to try to send such articles any

distance by trolley or steam roads. Our experience so far has shown that comb honey sent by parcel post has broken down in almost every case, even when well packed. The entire package or packages on arrival are one dauby mess, and the probabilities are that every thing in the mail-sack in which these packages came must have been daubed more or less. Similarly, nearly every parcel-post package that has been sent us containing liquids of any large quantity has been broken or leaking; and it seems to us it will be only a very short time before Uncle Sam will stop the shipment of liquids, syrup, and honey, especially comb honey, unless more precaution is used.

We presume we have had as much experience in shipping small samples of comb honey by express as any people in the United States. Our plan has been to wrap up two or three sections in paper, then in excelsior in a market basket, being careful that there was plenty of cushion or packing material between the fragile articles themselves and the baskets. As a general rule, commodities can go in a basket by express when they can not be shipped any other way; but parcel-post rulings do not allow a handle to a basket; but a basket may be used if the handle is folded down or cut off.

One difficulty about the parcel-post business is the fact that all packages go inside of a mail-sack. A big heavy package up to the 11-lb. limit bumping against a light one is almost sure to be disastrous to the latter, especially if it contains any fragile article such as comb honey or eggs.

In view of our experience, both with express shipments and parcel post, we would strongly advise against shipping comb honey by parcel post. It is conceivable that a single section might be sent as a sample; but it should be wrapped very thoroughly in paper, then in excelsior, and last of all inclosed in a strong wooden box that is capable of resisting a severe bump from an eleven-pound package in the same sack. But even then the section of honey should be wrapped in heavy manila or paraffine paper to catch the leakage if any.

We would at the present time discourage sending even *extracted* honey by parcel post, especially for long distances. It would be very unwise to put up a single package of, we will say, eight pounds of extracted honey in a box weighing only three pounds. About the largest amount that can be shipped would be in a five-pound tin. This should be wrapped thoroughly in excelsior in such a way that the excelsior will not

become displaced and leave a vulnerable spot for a severe bump. After wrapping it in excelsior it should be crowded into a basket with the handles folded down or cut off, and the top covered with a thin board and thoroughly tied with strong cord. But we do not believe there is one person in a thousand who knows how or can wrap up comb honey so it will go through to its destination by parcel post. Even Dr. Miller can't do it. See his *Straw* in this issue.

It is to be hoped that Uncle Sam will see the importance of keeping out of the mail-sacks bulky and heavy packages that just come inside of the eleven-pound limit, for it is certain that heavy packages should be left outside of the sack. Even though a higher rate were charged to cover the extra handling, it would not then be possible to ship bees in pound packages by parcel post. While there is no difficulty in sending a queen and a dozen or more of her attendants by mail, it is an entirely different proposition to send one pound of bees, or approximately 4500 individuals, in a closed mail-sack. "It can't be done." If that same Uncle will permit bees and other live stock like chickens to travel in wire cages or crates *outside* of the mail-sacks the same as express our problem would be solved.

THE NEW EDITION OF OUR A B C AND X Y Z OF
BEE CULTURE.

THE last form of this work for 1913 is just coming from the press. We have been at work on it for the last year and a half, and now we have it ready for the public. The new edition contains 750 pages, or 150 more than the former one. On account of rewriting so many of the old articles, and the incorporation of many new ones, making the book so much larger than formerly, we are now obliged to charge \$2.00 instead of \$1.50; but we believe that the reader will acknowledge that it is cheap, even at that price. Approximately it contains nearly 600,000 words. Any volume of this size on a technical subject like beekeeping would ordinarily command a price of \$5.00; but now, as in the past, we much prefer to make a small profit per volume on a large sale rather than a large profit on a small sale.

The new edition has been most thoroughly revised by E. R. Root, ably assisted by Dr. C. C. Miller, of Marengo, Ill., the veteran comb-honey producer; by Arthur C. Miller, of Providence, R. I., banker and beekeeper; by John H. Lovell, of Waldoboro, Me., naturalist, botanist, and entomologist; and by Prof. Eugene G. Baldwin, the one

who wrote that interesting series of articles on Florida beekeeping a year ago.

Up to now the old editions have been printed on standing type; but the extensive additions and revisions made it necessary to discard the old type which was becoming worn, and adopt a new scheme for getting out this work. To do this we purchased a \$4000 linotype type-setting machine, which also handles all the composition in *GLEANINGS* and our subsidiary publications.

The fact that the new edition was to be entirely reset, from beginning to end, made it possible to make the revision much more thoroughly than had ever been undertaken before. In many cases, instead of patching new matter on to the old it seemed more practicable to rewrite the articles entire. A notable example of this will be found in the case of foul brood. The former edition contained six pages, while the new has sixteen. In the same way, other old subjects were rewritten, while with many other subjects it sufficed to make mere changes and additions here and there. There will also be found an entirely new set of articles that never appeared in any edition of the work.

A notable feature of this last edition is the bee botany, which was entirely overhauled, and in many cases entirely rewritten, by John H. Lovell and Prof. E. G. Baldwin, mentioned above. The subject of Pollen and the Pollination of Flowers was almost entirely rewritten by Mr. Lovell. We doubt if there is another man in the country who can handle these subjects more ably than he. Dr. C. C. Miller to a great extent rewrote "Honeycomb." He also made important suggestions (which were adopted) on the subject of comb-honey production; and well he might, for he is now regarded as one of our best if not the best authority on the production of honey in sections. Mr. Arthur C. Miller, who for so many years made a close study of the internal economy of the hive, made numerous suggestions, many of which were adopted and incorporated in the text. In other cases, where he might or might not have differed with the author and reviser, his notes were put in the form of footnotes at the bottom of the page, and signed "A. C. M." In a similar way will be found an occasional footnote signed C. C. M. (Dr. Miller). The unsigned footnotes are by the author.

At first thought, as one glances over the new volume and observes that two-thirds or three-fourths of the matter was written by E. R. Root, he will wonder where A. I. Root comes in, and whether it is a case of "Hamlet with Hamlet left out." We are happy to say this is not the case. Some of

the best things that A. I. Root ever wrote on bees (and he wrote a good many) still appear in this volume, and always will. It is not so much because his writings have been stricken out of this edition, but because the immense amount of new stuff made necessary by the growth of the industry has made A. I. R.'s material seem small in comparison. His familiar style will be recognized, for example, in *Abandoning Swarms*; *After-swarms*; *Anger of Bees*; *Artificial Heat*; *Artificial Pasturage*; *Bee-hunting*; *Bee-moth*; *Italian Bees*; *Queens*; *Robbing*; *Stings*. What he has written under these heads will always remain as classic in bee culture. No man had more enthusiasm in the study of bees than A. I. Root, and that enthusiasm is so conspicuous that his writings can usually be picked out of the other matter, even though they have been skillfully interwoven with matter written by others.

Another feature of the 1913 edition is special articles by special writers. That is to say, we have sought the best writers we could find on any particular subject. Note, for example, the articles written by Prof. A. H. Bryan, of the Bureau of Chemistry, Washington, D. C.; by Dr. E. F. Phillips; Dr. Snodgrass; Dr. James A. Nelson; Dr. D. B. Castell—all of the Bureau of Entomology, and all experts in their line.

For several years back we have been looking for a botanist who is also a beekeeper, a naturalist, and an entomologist—a man who has done an immense amount of field work—one who has secured his information first hand. We finally found such a person in John H. Lovell, whose work seems to be accepted by some of the best scientists in the country. He has prepared most of the bee botany in this edition; and from a scientific standpoint we believe it will be up to standard.

Taking every thing into consideration, we feel proud of our new A B C and X Y Z of Bee Culture. It is new from cover to cover. It is the work of experts in their respective lines. It is the largest and most comprehensive bee-book in any language in the world; and yet it is sold at the popular price of only \$2.00. It will be clubbed with *GLEANINGS IN BEE CULTURE* at \$2.50. Old subscribers desiring to secure the new edition of the A B C and X Y Z of Bee Culture can, by the payment of \$2.50, advance their subscription one year and yet secure a copy of this magnificent work. It is so much of an improvement, so much of an enlargement over any of the previous editions, that one who owns an old copy can well afford to secure the new volume.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

THE man who winters bees in a cellar will cast a longing look toward outdoor wintering as soon as he begins to establish out-apiaries.

As an experiment I sent by parcel post to Chicago 10 sections of honey, none of them perfectly finished, in a safety shipping case. Postage was 46 cts.; expressage would have been 30 cts. Only four sections were unbroken, and the honey was reported "on the run." [See editorial.—Ed.]

OUT-APIARIES afford an extra chance for improvement of stock. The best colonies can be massed in the home apiary, or one of the out-apiaries, and queens can be reared there with a better chance to meet the best drones. Then when the young queens are laying they can be distributed to the other apiaries.

P. C. CHADWICK, p. 174, complains that the cost of parcel post for honey is prohibitive beyond the first zone. Perhaps hardly so bad as that; for in zone 2, with nine times as large a territory, it's only 4 cents a pound; but it's not what we should have. From here to Chicago, 66 miles, 7 pounds costs 30 cents by parcel post; by express 25 cents. Eleven pounds costs 46 cents by parcel post; 30 cents by express. Uncle Sam can work for as little as the express company, and ought to.

A GOOD many, at least in Europe, take seriously the idea that larger bees can be produced by using foundation with larger cells. No less than 2500 Rietsche foundation-presses have been sent out with 736 cells to the square decimeter instead of the usual 854. That is, the cells were made with about one-sixth greater area than usual. [Does a large cell make the bees any larger? We doubt it. If, however, the cells are smaller than the normal size, the bees will be smaller, just as a Chinese woman's foot is made smaller by being put in a small shoe. As Cheshire has pointed out, there would be no advantage in having a larger bee, as such an insect would be out of harmony with the flowers for which they seem to be specially adapted by the great Creator.—Ed.]

REPRESENTATIVE LEWIS, one of the most interested members of the congressional committee on parcel post, favors this rate: Three cents a pound for the first pound, and half a cent for each additional pound up to 100 pounds for the first hundred miles, then half a cent additional per pound

for each additional hundred miles. By the Lewis rate a package of 12 sections, weighing, say, 14 lbs., would cost 10 cts. within 100 miles, and 17 cts. within 200 miles. Exactly this may not come; but something like it is likely to come before beekeepers are ready for it; for I don't know of any proper package ready for posting honey—do you? [There is a great future for parcel post; but before honey or bees can be shipped in that way some provision will have to be made whereby they can be sent like ordinary express matter in separate packages by *themselves* instead of in a closed sack. Bees in pound lots would smother in a sack. In a jumble of packages in a sack, large and small, comb honey would stand a poor show.—Ed.]

It is well known that cold favors granulation of honey, but it is not so well known that frequent change of temperature may be a still stronger factor. In *Ill. Monatsblætter* is given an instance, p. 21. Buckwheat honey in cans was set out where the sun shone upon it by day and it cooled off at night. In three or four days it began to candy, while in the steady temperature of a room honey out of the same lot remained liquid for weeks. [You say it is "not so well known that frequent changes of temperature may be a still stronger factor" in causing honey to granulate than cold. Those who have read late editions of our A B C and X Y Z of Bee Culture—yes, for five years back—must have seen where we have said that "the primal cause of granulation is the alternation of warm and cold weather." See subject of "Candied Honey." Then toward the latter end of the subject see this: "Continued zero weather is not so favorable as weather somewhere near the freezing-point, now moderating up to the thawing-point, then freezing and then thawing. When the weather remains continuously cold, set the honey out in pails or boxes in a room where the temperature goes a little below freezing, leaving it for a day or two, then move it into a warm room." At various times in these columns we have stated that changes of temperature will cause granulation much sooner than mere steady cold. As a rule you can leave liquid honey in a temperature 10 degrees below zero for weeks, and it will remain as clear as crystal. But a freezing and a warm temperature in alternation, day after day, for about a week, will begin to show results in that same honey. We therefore entirely agree with *Monatsblætter*.—Ed.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

The so-called "pickled brood" has at last a definite descriptive name—"sac brood." It has also been discovered that it is to some extent infectious, as I have feared it might be. The United States Department of Agriculture has just sent out Circular 169 of Bureau of Entomology, fully describing the disease. This is the disease I spoke of on page 21, Jan. 1.

* * *

Dr. Miller quotes from *Deutsche Bienenzucht*, page 4, Jan. 1, regarding the necessity of a brood-chamber so bees can cluster in a sphere. A spherical cluster of bees in winter is not necessary where the brood-chamber is well packed. I often winter bees on four combs, and small nuclei on three combs, with success. It is always well to reduce the size of the brood-chamber to the size of the colony.

* * *

The editorial in regard to the color and temper of Italian bees is golden. I was much interested in a remark made to me by Mr. Frank Alexander, of Delanson, N. Y., last spring. He said he didn't like cross bees. I have had some experiences the past year in inspection work that I don't care to have repeated. I have found some that I wouldn't keep if you would give me a whole yard for nothing, set in the richest pastures flowing with honey.

* * *

On page 8, Jan. 1, Mr. Doolittle discusses the profligence of queens vs. longevity of bees; and he appears to have the argument on his side. It was a favorite theory with Napoleon that Providence favors the largest armies, and we beekeepers have been working on that principle very largely. The condition of a colony will often influence the amount of work done. A new swarm will sometimes accomplish twice what it did before swarming. I could not help wondering, after reading Mr. Doolittle's statements, whether there is any thing to hinder our having both a prolific queen and long-lived workers combined in the same colony. If we add to these gentleness and honey-gathering instincts, we shall have almost ideal bees.

* * *

From a Straw on page 40 it would seem that Dr. Miller and Mr. Morley Pettit do not think alike on the subject of European foul brood. Well, never mind. I have no doubt they would if they lived in the same locality and kept the same race of bees. A

great deal has been laid to locality in bee-keeping, and I have come to the conclusion that locality plays quite as much a part in European foul brood as in any thing else. In some sections it spreads with great rapidity, but slowly in others. For several years it has existed within two miles of one of our yards, but as yet I have not found a trace of it in our yard. It appears far less contagious in some sections than others. I remember one yard I inspected where it had been for two or more seasons without spreading beyond these two or three colonies. In low damp or hot localities it seems much worse than on high land or in a colder and dryer climate. I have noticed a decided difference in different yards in the same locality. Some strains of bees appear to be almost immune, while others succumb to it very quickly. I believe at the present time it is of much more importance to breed a race of bees that will contend successfully with this disease than to breed for the largest number of yellow rings on their abdomens.

* * *

Of immense importance is the editorial, page 38, Jan. 15, on the value of windbreaks for winter protection for outdoor-wintered bees. I have called the attention of the readers of *GLEANINGS* to this subject several times, and should have said more, but did not want to be considered a crank on the subject; but when I see every colony dead in that part of a yard most exposed to the prevailing winds I know that this exposure had much to do with the wintering of bees. For many years in locating a yard of bees on a new site I have considered protection from the wind quite as important as a good range or pasturage for the bees. We winter almost entirely out of doors; but like other good things, this matter of protection may be overdone. Mr. Halter wisely calls attention to this on page 56, Jan. 15. I have known a yard almost completely ruined by too much protection. A friend of mine built a high tight fence on the northwest and south sides of a small yard while his house was on the east side; and when the bright sunny March days came the bees flew, most of them never to return to their hives. The protection should be such that, as soon as the temperature of the yard becomes much warmer than the outside air, the air of the yard will rise, and the cool air from outside will quickly take its place, thus keeping the temperature of the yard near that outside.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

The women's number of GLEANINGS was a nice one, and I should like to make some comments on their ideas; but I have been a married man 17 years, so I pass.

* * *

Mr. J. W. George, at the State convention, asked why the cotton of Imperial Valley does not yield honey. It occurred to me afterward that it must be due to the nectar being very thin and the climate very hot and dry, causing a condition much the same as in the orange districts when extremely hot weather causes the rapid evaporation of the thin nectar from the orange bloom.

* * *

J. E. Crane, p. 57, Jan. 15, says: "The ignorance of the great mass of beekeepers is past comprehension. So far as I can learn, not more than one in six, in some sections, ever read a bee journal of any kind." This reminds me of a friend who invited me to dinner with him while at the recent State convention. On our way to the cafeteria he frankly (I like these frank open-hearted folks) opened his heart to tell me he had criticised me at a certain meeting for making a statement much like the above, saying he thought I was a little severe in the matter. Now Mr. Crane reports the same from his travels, and even a little worse. Bro. Crane, if any one has his doubts about the matter, let him take a similar trip and be convinced.

* * *

Western migratory beekeepers should study the question of shipping bees without combs. The problem of having their bees quarantined, as some of our western beekeepers have had theirs, might be overcome by having two sets of hives and combs, and shipping the bees from one locality to another in full-swarm packages without combs. At a reasonable express rate it might be cheaper and fully as profitable to have a full swarm to begin on an alfalfa flow as to have a hive containing mostly brood to begin the work; for if I have been correctly informed it is a difficult matter to get the old bees through when transporting them with the hives and combs. The greatest difficulty would be when shipping back for the orange-flow, which would have to be done in the fall immediately after the alfalfa season was over, and to get enough natural stimulant to start a force of young bees for early spring breeding. The stores for winter could be reserved at the end of the orange-flow. I believe it would be worth a thorough trial at any rate.

I have read with interest the discussion as to whether we should encourage more to keep bees or render more help to those already in the business. My idea on the question would be to offer first aid to those in the business, and not encourage those not in to go in, for there is going to be a continuous line of young enthusiasts enter from year to year, and they are the ones who need encouragement. Enthusiasm is half the battle, and is necessary to success in this line of business. One poor season will cure a bad case of bee fever where there is no enthusiasm to complicate the case; but where there is this complication, you may as well count the case incurable, and give every aid possible to the patient. I believe the teaching of apiculture in agricultural or even in high schools would be a most excellent line of knowledge for the general information of a public that has little or no knowledge on the subject compared to other lines of knowledge. If we could overcome such expressions as "rob the bees," "strained honey," and "bee gums," it would give a little higher conception of the business. I feel, however, that we are outgrowing those expressions to some extent.

* * *

A correspondent recently wrote me, saying the brood-chambers of his hives were honey-bound, and asked what I would do to relieve the situation. Circumstances enter very largely into the case any way you may figure it. If, in my judgment, they had sufficient bees to cover an extra comb I would slip one in the center of their brood-nest, expecting the queen to lay it full of eggs at once if the breeding season were at hand. Then I would watch developments. If the eggs were laid as expected, and honey coming in but very slowly, I should expect that to relieve the situation; and if, after the larvæ in the new comb had reached the stage where they were demanding the most stores, there should come two or three days of bad weather I would clap my hands and say, "Good! eat it up," for that would give them additional relief. But if honey were coming in freely, and there were only a limited time until the main flow was at hand, I would extract some of the combs to relieve the situation and give the bees a chance to start brood-rearing as rapidly as possible. If there were very much brood started, and bad weather expected, I would be very careful to leave them plenty of stores to carry them safely.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

WORKING BEES BY MOTOR-BOAT.

Not all beekeepers are so fortunately situated that they are enabled to carry out certain advanced ideas on a large scale. One of the chief ones of these is the management of big strings of out-yards, by means of the automobile. This is prevented by two main reasons, as a rule—the lack of suitable locations on one hand and the want of better roads on the other, or both. Fortunate is the one who can locate any number of apiaries in easy access from good automobile roads. That is one of the greatest essentials in real up-to-date extensive out-apiary management to-day. Of course this has no reference to the smaller number of apiaries owned by many beekeepers who are successful with that number.

Grant Anderson, of San Benito, Texas, well known as a queen-breeder, has made use of two automobiles for a number of years. He uses a light high-wheeled buggy, motor-driven, as a roadster in which to run to the various apiaries and other places when no hauling is to be done. For hauling trips he uses one of the light high-wheeled delivery wagons. These have given him excellent service and satisfaction, especially for pulling through muddy and sandy roads. In this respect the high-wheeled machines seem to have an advantage.

Recently we have been informed that Mr. Anderson has now all, or nearly all, his apiaries located on the banks of a river, and runs from one to another in a motor-boat. This would indicate still another step toward "hastening" beekeeping work in the management of large and numerous out-apiaries. It is to be hoped that the readers of GLEANINGS may be favored with an article and photos, showing this man's doings per motor vehicles and motor boats, for we have written Mr. Anderson to give us information.

* * *

A COLD SNAP.

While we have had quite a cold winter in Texas this year, there was not much severely cold weather. The cold weather was much more evenly distributed than during most of our average winters, and only occasionally did it get so cold that standing water was frozen over, and then only to a thickness of less than an inch.

During the last two months there was much warm weather during the middle part

of the days; but as a rule the nights were quite cold. The latter did not affect our early bloomers, however; and, in fact, there were all evidences that spring was here in the fore part of March. This has reference to the central part of the Lone Star State, the northern part having had still colder temperatures. Against this, however, southwest Texas was enjoying real spring weather; and reports from the more southern portions of this territory were to the effect that bees were storing honey rapidly enough to keep them too busy to swarm. It will be remembered that a honey-flow at swarming time stops all, or practically all, swarming in our part of the South; hence these reports show that quite a honey yield must be on to prevent the early swarming that may safely be expected at this time, with a moderate yield of nectar and pollen.

However, after all this beautiful weather and brightest prospects for a spring crop, the temperature dropped suddenly to 28 degrees on March 15; and the result was disastrous. Especially did it affect the fruit bloom, which was in full blow. As a consequence, the fruit crop will necessarily be short again this year. While the bees were materially affected by the destruction of this source just at a time of heavy brood-rearing, yet the beekeeper may safely figure on a somewhat better market for his products than when fruit is very plentiful. Although some beekeepers do not seem to think that this has any effect on the honey market, our own experience has shown time and again that there is a sudden slackening in the demand for honey as soon as much fruit reaches the markets.

We do not know how much the bees were affected. There was considerable young brood; and, owing to the warm days previous to the cold snap, the bees were scattered out of cluster so that, as a consequence, brood was not protected properly against the suddenness of the cold wave. In addition to this there followed several days of cold weather, preventing the bees taking proper care of all the brood. Therefore we found some colonies carrying out some dead brood on the following warm days. All in all, however, the damage does not seem to be great, especially to those beekeepers who are paying close attention to the great amount of stores now needed by the heavy brood-rearing colonies.

Conversations with Doolittle

At Borodino, New York.

WEALTH-PRODUCERS.

"Mr. Doolittle, I came over to have a little chat with you about the middleman as a wealth-producer. We are hearing much at the present time about the high cost of living. Does not every one of the dealers add to the cost of living without producing any wealth? This question was brought up to my mind when I was thinking of buying my bee supplies for the coming honey harvest. I find that, as a rule, I can get these goods no cheaper of the dealer than of the manufacturer; but the dealer must have quite a large slice out of the pockets of some one in order that he can be allowed to live in idleness. Why I say idleness is because a prominent political economist told me the other day that a trader or dealer adds nothing to the real wealth of society."

"Suppose we ask the question, What is production? and who are the producers of wealth? Take, for instance, the section material we need for use when we are engaged in the production of section honey. The man who takes a plank of wood and cuts section material from it is not the only producer who has brought human energy to bear upon it. The man who cut the tree up in the north woods of Michigan or Canada helped to produce that section. The man who drew the log to the mill, and the sawyer at the mill who sawed the log into plank, and the transportation company who transported it to the manufacturer of sections; the party who took the finished sections and put them down where they were to be used, and the man who received them and held them in his storehouse until the beekeeper was ready to exchange the fruits of his labors for them, all had a hand in the *production* of those sections.

"Let us go a little further: Every one who put forth any energy in getting the section to the place of consumption was a producer of sections so far as that section and the individual consumer were concerned; for to leave any of them out would deprive the consumer of his sections at the proper time and place. You live in central New York, and the section was made at Medina, Ohio, we will say. That section would be of no use to you until it found its way to central New York. And it seems almost ridiculous for me to say to a man of your intelligence that this section could come through the regular channels of trade cheaper for you than in any other way. It is true that you might stop work and walk out to Medina and bring the section back

in your pocket; but I will not insult you by saying that such a method would prove more expensive than to have it carried by a 'soulless railroad corporation' at the direction of the so-called 'useless middleman.' No: the dealer is not an idler by any means.

"Let us look at the finished product of our section honey for a moment. Where did such production begin, and where did it end? Are the bees the producers, or is the man who manipulates the bees the chief and only factor in the production of honey in sections? When is this production completed? and when does the act of production cease and that of consumption begin? Is it not plain that production ceases when the honey is in the hands of the consumer, and not before? If this is so, then every man or woman who had any part in getting the honey in the hands of the consumer is a real producer.

"Then there is a point as regards the dealer in honey, which is almost always overlooked. The dealer, as a rule, helps create a desire for our finished product, and, therefore, has much to do with the production of section honey. Whatever satisfies human desire can properly be called wealth; and if there were none desiring our honey it would, to say the least, be a useless production which we should be in. There must be a desire for our finished section honey before it can be called wealth; therefore the dealer or 'drummer' who creates a desire for our product must of necessity be called a producer.

"It is apparent from this that the dealer is valuable in more ways than one. He not only helps to sell our product by creating a want for it, but he brings goods to the point of consumption at less cost than they could be brought by the consumer, and at a saving of time. He keeps on hand ready for the consumer such goods as he may want, and at the time he wants them. This relieves the consumer of all anxiety and responsibility, and he has the use of the money up to the very time when he is ready for the article he needs. The nearer the article is to him when he is ready for it, the longer he can wait before he gets it. The dealer has to assume all the risk; and any man who knows any thing about the honey business knows that this is no small item. There is a possibility that we may have too many dealers—that some of these dealers are over-reaching and unwise. But it is sometimes well to ask ourselves these questions, else we become uncharitable."

General Correspondence

SUGAR SYRUP VS. HONEY

Mr. Byer Makes his Position Clear, and at the Same Time Shows that he is in Harmony with the Rest of the Beekeeping World

BY J. L. BYER

GLEANINGS for March 1 is just at hand; and as I read the editorial comment regarding that note of mine concerning the value of *syrup* as compared to good honey as to *lasting* qualities, I rubbed my eyes and hastily turned to "Notes from Canada" to see what foolish things I had been writing to put me "practically in opposition to all the rest of the fraternity." Now, while I would rather enjoy being in such a unique position as that, if sure that I was *right* and all the other fellows wrong, in this case I have not the slightest idea that such is the case, as I personally know that a large number of extensive beekeepers who have to feed lots of sugar every fall are right in line with me on this question. In the first place, I want to say that, *all* things considered, I do not think there is any thing quite so good for bees—certainly nothing better—than first-class honey sealed in the combs. Secondly, I believe that for our cold climate there is nothing in *general practice* that we can depend upon for safe wintering so good as thick syrup made from the best quality of sugar; and I am and have been right along an advocate of heavy feeding for winter if we wish to be sure of wintering successfully in our cold climate. Why this apparent contradiction? Simply because, under modern methods of extracted-honey production, we can not have any great quantity of first-class honey in the brood-nests after the supers are off. Indeed, in most cases there will be little honey of any kind; and what there is will be of late gathering, which is usually inferior to clover or basswood honey for wintering purposes. The saving of combs of clover honey for winter is not practical, and is not economical when colonies are kept by the hundred; as, for the winter months alone, good well-ripened syrup is equal to or better than the best honey. For spring I prefer the honey by all means, especially if the weather is too bad to allow free gathering of pollen.

Now, while I am right with the editor as regards the advisability of feeding sugar syrup for winter stores, the point of difference is the comparative values of a pound of syrup in a feeder versus a pound of good honey already sealed in the combs. I say

that it takes a pound of sugar in a feeder to equal a pound of sealed honey, while he contends that a pound of *syrup* has this value. The word "*syrup*" is very indefinite unless density of the same is mentioned; and whatever he may have had in view, I am referring to a syrup made of two parts of sugar to one of water, that being the proportion I always use for fall feeding.

While I have no *figures* to back up my contention in this matter, a lot of actual experience, often with a lean pocketbook to make me very careful in the matter, has convinced me thoroughly that it takes a pound of sugar when made into syrup, and fed, to equal a pound of sealed honey; and I now always figure on that basis when preparing for winter. If any one wishes to try the experiment in a simple way he can try the following, as I did more than once when at different times I had bees given to me in the fall, the owners not wishing to feed up colonies practically destitute of stores. This was when I was getting bees wherever I could, and at a time when they were more easy to get than is now the case. Strong colonies of bees were shaken on empty combs, and brought home to be fed up for winter. In some cases, when I had combs of honey on hand, they would be given these; but generally I had to feed them sugar syrup for wintering. At that time I believed that two-to-one syrup was equal, pound for pound, with sealed honey; but I soon got my eyes opened on the question. I would feed these destitute bees the 30 lbs. of syrup made by the two-to-one plan; and every time I would have to look after those colonies in the early spring to prevent starvation, while the colonies with *30 pounds of sealed honey* would have enough to carry them through. After a few experiences of this kind I began to investigate; and while I believe that a pound of syrup *sealed in the comb* will equal at least a pound of honey, that is an altogether different proposition from saying that a pound of syrup in a feeder equals a pound of sealed honey, as we all know that 30 pounds of syrup will not weigh nearly that much three weeks after it has been given to a colony. This shrinkage is very heavy—just why, I can not say definitely; but I suspect that quite a bit is lost in wax secretion, as whenever bees are fed they seem to secrete wax scales, whether comb-building is necessary or not. So as a matter of fact a colony fed a given amount of syrup is not as heavy to start out with as is the colony with sealed honey in the hive equal in

weight to the one we endeavor to bring up to standard by feeding syrup. Any one testing this must be sure that they have the amount of *honey* to start with, as very often about 20 pounds of honey and 10 pounds of *pollen* pass for 30 pounds of honey.

As I said at the start, I personally know that many of our heaviest producers now agree with me on this question; and, indeed, it is not so many years ago that I contended that thick syrup in a feeder equaled sealed honey pound for pound. Mr. John Newton, of Thamesford, Ont., was arguing with Mr. Sibbald and myself at a convention on this matter, and we both disputed his claim vigorously when he claimed that a pound of sugar was necessary to equal a pound of sealed syrup; but much against my will I have been forced to agree with him; for in so far as the purse is concerned, I certainly wish that such were not the case. But even on the basis of a pound of sugar to equal a pound of sealed honey, we still get mighty good value for the change. Just now, if I had good honey to sell I could easily get 12 cts. a pound for it, and I can buy the best granulated sugar wholesale at $4\frac{1}{2}$ cents a pound.

In conclusion, then, I certainly advise and practice feeding syrup for our cold winters, both as a matter of security and economy; but I am perfectly satisfied that for "our locality" it takes a pound of sugar mixed with half a pound of water to equal a pound of good sealed honey.

Mount Joy, Ont., Canada.

[When Mr. Byer in his department on page 141, March 1, put out a challenge to the editor in this language, "Surely you do not believe that a pound of syrup will go as far as a pound of good honey?" and then further on in the same item says, "While I have to feed lots of sugar syrup some falls, certainly I do not place that proportionate value on the syrup as compared with honey," we naturally concluded he was making the comparison under *like conditions*. That is to say, we thought he was contending that a pound of sealed honey in the combs was much superior to a pound of sugar syrup sealed in the comb; but in the article above he now makes it very plain that what he meant was that a pound of syrup before it is fed would not equal a pound of honey sealed in the combs. This being his position we nearly agree with him. We do not know, however, that we are quite prepared to believe that it takes a full pound of sugar, when made into a two-to-one syrup in a feeder, to equal a pound of honey sealed in the combs. A good deal

would depend on what time of the year this syrup is fed. If it were very late in the fall, when it is cold, and were given in one large feederful, say 25 lbs., our opinion is that the loss would not be as great as he estimates. If, however, he fed this two-to-one syrup early in the fall, then we are quite prepared to believe that it would take fully a pound of sugar in the feeder to equal a pound of honey sealed in the combs. All in all, we doubt if there is any difference of opinion between us, now that we understand each other. In all events, we are glad to place in this connection a short item from Mr. R. F. Holtermann, who supports the position taken by Mr. Byer.—Ed.]

Regarding the value of honey and sugar syrup, I consider that, from experience with honey and syrup side by side, as a winter store the sugar syrup is the safer winter food for bees. If, however, we feed and want a colony to gain, say, 20 lbs. of stores, I estimate the quantity by the number of pounds of sugar in the syrup rather than the weight of the syrup. For instance, if I want a gain of 20 lbs. I take 20 lbs. of sugar, and make it into a syrup, and feed it to gain the desired weight. The percentage of waste is greater when a less amount is fed, and in my estimation (and I act on this in practice) I never think it worth while to feed less than 10 lbs. of syrup with the object of securing a gain in weight worth while. Rapid feeding is also desirable to keep colonies from starting brood-rearing, and to prevent unnecessary waste in storing and ripening the syrup.

Brantford, Ont. R. F. HOLTERMANN.

HONEYBEES AND POLLINATION

The Wind of Little Value in Pollinating Fruit-trees

BY GEORGE H. WEST

The conclusions of all eminent horticulturists agree on the necessity of the honey-bee in orchards for effective cross-pollination, large fruit crops, and perfect fruit. The result of exhaustive experiments and observations, covering over twenty years, shows that most of our tree fruits are self-sterile—that is, they either produce no fruit from the pollen of their own blossoms (or that from the bloom of the same variety), or but a small amount of fruit, and this largely under-sized or defective. Self-pollination would be such as the wind might give, while cross-pollination would be bloom fertilized by the pollen from other varieties of the same species, and by insect visitation.

Wauyah, of Massachusetts, demonstrated

that plum pollen is not transmitted through the air in sufficient quantities to ensure self-pollination. Profs. Lewis and Vincent (Oregon State Agricultural College, Bulletin No. 104), experimented with plums, and reached the same conclusions. Their experiments on the action of the wind in apple pollination with varieties known to grow abundant pollen at the height of their bloom, and with a strong wind blowing, showed no effective deposit of pollen twenty feet from the trees and nine feet from the ground, nor thirty feet away, and at a height of six feet.

The writer's belief, from observation of some forty years in Colorado, where we have much wind, is that the winds are a positive damage to effective apple pollination. We have often observed apple trees that had little or no fruit on the north and west sides (from whence our prevailing winds). The deduction was that the pollen and petals were blown away. But we noted, also, later, that *bees rarely visit blossoms when the pollen is gone*, hence no proper fertilization and little fruit. For verification we cite the experiments of Lewis and Vincent, where all the petals and stamens were removed from the 1500 blossoms on a seven-year apple tree, leaving it exposed to both the wind and insect visitation. This tree was 20 feet from another that bloomed profusely. *Out of the 1500 blossoms emasculated, only five set fruit.* During the whole period (days) that the pistils of these blossoms were receptive, only eight bees visited the tree. More than twice that number were seen in one half-hour on the tree twenty feet away.

Certainly the forest trees and bushes, and most of our field crops, seem to secure proper pollination by the winds; but all authorities now agree that our tree fruits secure it effectively only by insect visits. If the theory is true, that all bloom which, in the economy of nature, supply nectar, *require* insect visits for effective fertilization and reproduction, then the bees which gather honey so largely from alfalfa clover *are a necessary factor in growing alfalfa seed.*

Prof. M. B. Waite, United States Department of Agriculture, Bulletin No. 5, "The Pollination of Pear Flowers," made experiments to determine the value of insect visitors in pear pollination. Of 36 varieties of pears tested on 142 trees, only nine proved self-fertile above five per cent. The experiments showed a great increase, both in the yield and size of the fruit, from cross-fertilization. Waite says, "It has been proved that cold weather, during the flowering pe-

riod, renders some plants incapable of self-fecundation, although they still retain the ability to be cross-fecundated." Observations by growers in Indiana and Utah confirm the truth, also, that cross-pollinized apples have more vitality to resist freezing weather and insect and fungous injury. Waite says, "Apples are more inclined to be sterile to their own pollen than the pears. * * * In the majority of cases no fruit resulted from self-pollination."

The experiments of Prof. S. W. Fletcher, Virginia Agricultural Experiment Station; of Prof. A. J. Cook, Horticultural Commissioner of California; of Profs. Lewis and Vincent, and others, all reach the same conclusions. They give little value to pollination by wind, and all give due credit to the busy bee. Fletcher's experiments showed that Bartlett pears, on 3081 tests fertilized with their own pollen, *produced only six small pears, or one fruit to 513 blossoms*; while with pollen from other varieties it grew one fruit from seven to ten blossoms, and these pears were over fifty per cent larger in size. Also, the Kieffer pear, on 1268 blossoms fertilized with its own pollen, *grew but five fruits, or one to 263*; while on cross-pollination, with other varieties, it yielded one fruit from three to seven blossoms.

In the Lewis and Vincent tests, self-pollinated Spitzenberg apples proved inferior in size, and ill-shaped, compared with the cross apples, and were practically devoid of plump seeds. On the yellow Newtown apple tests the results were the same, except that the average weight of the seeds from the cross-fertilized apples *was forty-six times greater* than from the self-fertilized fruit. Imperfect pollination can not produce perfect fruit. It is often "lop-sided."

Oregon circular bulletin No. 20 says, "Careful experiments have shown that very little if any pollen of our tree fruits, other than nut-trees, is transported by the wind. Probably 99 per cent or more of the transfer of pollen is done by insects. Prime among these may be mentioned the honey-bee."

The Bureau of Entomology, Washington, says the annual value of honey produced in the United States is \$20,000,000; but that *the service the bees render in fertilizing the blossoms of fruit trees is worth many times twenty million dollars a year.*

The bloom period of tree fruits is very short. The winds waste the pollen; the rain washes it from the blossoms, and drouth injures it. The pollination period is often greatly shortened by rains or cloudy days, when the bees do little work. For their

greatest effective work, the *hives of bees should be in the orchards*, and perhaps near those varieties that are the heavy pollen-bearers. Some honeybees work at night in Colorado and Idaho. Growers there think one average hive of thrifty bees for each two acres of mature orchard necessary for effective pollination. The hairy covering of the body and legs of the honeybees, and their brushes and combs for gathering and carrying the pollen, make their visits more efficient than those of other insects.

From some flowers the bees take only nectar; from others, only pollen; and some bees at times gather nectar alone, and others pollen alone; for bees make their pollen-collecting trips during the morning hours (Casteel).

The harmony of nature and the divine law is shown in these facts, that the tree-fruits bloom early, each in its own time and order, so that each gets its own pollen, and at a season when the honeybees are usually most of the flying insects present. They are numerous, active, and are insatiable and untiring gatherers of both nectar and pollen from the fruit blossoms. Then the rapidity and great increase in numbers of the bees is another favoring factor.

Chas. A. Green (Rochester, N. Y.), the well-known horticulturist, suggests that a single honeybee may visit 100,000 blossoms in gathering an ounce of honey; while D. C. Polhemus, a Colorado apiarist, says that a bee visits about 125,000 blossoms in making a *pound* of honey. If either estimate be true, and there are some 100,000 bees to every thrifty hive, surely effective cross-pollination could be secured with a hive to each two acres.

The use of bees in greenhouses, for fertilizing the bloom of vegetables grown for early markets, has been long a recognized necessity. The demand for bees for cross-fertilizing orchards is insistent. It should be a universal practice.

Colorado Springs, Col.

HOW TO PUT IN BOTTOM STARTERS

BY EMMA WILSON

Dr. C. C. Miller.—Several times I have tried to put bottom starters into sections, but could never make a success of it. With full-size foundation I have no difficulty. My Daisy foundation-fastener is of the old style, with a high rounded top coming above the section. To facilitate the removal I cut a deep groove into which I can insert a finger behind the foundation, and with the end of the finger support this, while I take the section away.

However, with the bottom starters it is different. The block (against which the foundation rests) always gets very warm, and covered with a waxy film to which the bottom starter adheres, so that,

when I remove the section, the starter either sticks to the block or drops over backward, and, in the latter case, if I try to raise it up it comes loose from the section.

WM. MUTH-RASMUSSEN.

Independence, Cal., Jan. 20.

Dr. Miller has placed this in my hands for reply, saying that it is much more in my line than his.

Putting in bottom starters is so easy for me that it is almost done mechanically. Still, I can imagine conditions that would make it difficult. We use the same style of Daisy foundation-fastener that you do, and I can not see why you need to cut any groove or need any support from behind in putting in the large top starter.

Now as to that troublesome bottom starter. I wonder if the chief difficulty is not that you cut the starter too narrow. Even so good an authority as A B C and X Y Z of Bee Culture gives the depth $\frac{1}{4}$ or $\frac{3}{8}$ inch. We find $\frac{5}{8}$ inch the best depth. If the starter is too narrow it is much harder to fasten in, and the bees will be apt to gnaw it down. It seems to me a $\frac{1}{4}$ -inch starter would be very difficult to handle, and even an experienced workman would make very poor work with any thing so small. The bottom starter is always fastened in first.

If foundation must be put in during very warm weather, use the early morning hours for the work, and keep the foundation as cool as possible. Do not allow the wood of the section to become heated. If this happens, take a fresh section, and allow the heated one to cool. The quicker the work is done, the better; so, if possible, do not get nervous over it, as it will help a whole lot if you yourself can keep cool too.

I will now try to tell, as well as I can, just how it is done at Marengo. Take a section upside down with the right hand. Place it on the machine; then with the thumb of the left hand at the bottom of the section at the left end, and fingers of the same hand at the top, push the section and machine back so that the section will be under the plate, and at the same time pick up the bottom starter from the lap with the right hand. Put the starter in place against the block with the edge resting on the plate, keeping the tip of each fore finger pressing lightly on the top edge of each end of the starter. Then very quickly pull back so that the starter will slip off the hot plate, and hold in position not more than a second. If the work has been done quickly so that the wood of the section has not been heated, the foundation will cool in that time so as to hold firmly when the section is reversed to put in the top starter.

Marengo, Ill.

SHIPPING BEES IN POUND PACKAGES WITHOUT COMBS

New and Old style Cages; Construction of Cages, and How to Prepare Bees for Shipment

BY E. R. ROOT

There is no one subject, perhaps, that has been introduced during the last six or eight months that has called forth more correspondence than the one now before us; viz., how to ship bees without combs for the purpose of saving express charges, and eliminating the possibilities of transmitting disease.

For years we have sent bees in pound and half-pound packages; but it has been only within the past two years that we have attained any degree of success. Some fifteen or twenty years ago, when we shipped bees in this manner we lost fully fifty per cent during transit—so much so that we finally gave the business up in disgust. But two years ago it seemed to be more important than ever that we should devise some scheme by which we could send bees without combs, on account of the general prevalence of bee disease; for combs are the chief means for the transmission of infection from yard to yard and from one locality to another. Indeed, we may say that, were it not for the moving of hives of bees from one place to another, foul brood would be confined to a comparatively

narrow area. But it has been pretty definitely proven that bees shaken or brushed from combs may be placed in any clean hive or package without danger of carrying disease. In fact, the basic principle for the treatment of foul brood is the separation of the combs and honey from the bees having foul brood. The pound package calls for neither combs nor honey; and, what is more, a given portion of bees can be shipped without them at about one-fourth the expense for express charges that would be required were combs sent. But it may be argued here that the combs may contain brood, and that this brood will hatch into bees. On the other hand, we may say that all "unsealed" brood will be removed or starved. Unless bees have water given to them *en route* at frequent intervals they will not take care of their unsealed larvæ. But the shipment of brood in any form involves the danger of carrying disease; and the time may come when legislation will entirely bar out the traffic in bees with combs. In the mean time it behooves all shippers of bees on combs to take extra caution to see that their yards are clean, and, so far as possible, encourage the purchase of bees in combless packages, or what has been popularly termed "pound packages."

We said a little way back that, during the last year, we have been quite successful in shipping bees in pound packages, when

FIG. 2.—One-pound cage dissected, showing internal construction of new style.

our earlier experiments were any thing but satisfactory. The cause of our former failures we now know was due to two conditions—lack of water in hot weather and the absence of suitable supports in place of combs for the cluster.

Years ago shipment of bees in pound packages during hot weather was nearly always attended with loss, requiring at least fifty per cent of replacement. During the past summer we discovered that we could eliminate this loss almost entirely by giving the bees a bottle of water. In some cases

there was a failure because the bottle did not feed the water fast enough. The most suitable container for the water seems to be an ordinary self-sealing tin can. The top of the can (or what will be the bottom), after filling with water, is perforated by a hole a little larger than one made by a good-sized pin. This bottle, after the case is filled with bees, is secured to a wooden cap that closes the hole in the top of the cage. See Fig. 1. The middle cage shows a tin can with a perforation in the bottom. Across the top is soldered a sheet of tin. This acts as a support for the bottle after it is inverted and set down in the hole in the cage. A wooden cap covers the hole. The style of tin bottle shown in Fig. 1 is not used now—that is to

say, we now employ a regular self-sealing can instead, the bottom of which is secured to a wooden cap that closes up the hole in the cage.

The other requirement we found necessary was some means of support for the bees while in transit. Years ago we dumped the bees into a wire-cloth box, when they would shortly form into a cluster like a little swarm, thus hanging on to each other for the whole trip. While bees can hang in the form of a swarm for a short time, experience has shown that it is more natural for them to hang on to something, and why not? Just notice how a swarm will show an inclination for a large bushy limb with little limbs projecting in all directions. With that idea in view we instructed one of our men to make up some cages with a series of wooden slats passing centrally through the cage. In Fig. 1 these slats are shown only indistinctly; but in the more modern cages (see Figs. 2, 3, 4, 5, 6) the slatwork consists of a series of fences—slats about $\frac{3}{4}$ inch wide, and spaced about half an inch apart. A series of these fences are slipped down into grooves in the ends of the cages. See Fig. 2. Two of the central fences are cut out to make room for the water-bottle, as will be seen.

In this connection it is proper to remark that the cages shown in Figs. 2, 3, 4, 5, 6

FIG. 3.—New style one-pound cage for shipping bees without combs.

are much better and stronger than the old style shown in Fig 1; and, moreover, when the water-bottle is mounted in place, the strap handle will always keep the cage right side up and the water-bottle right side down so that it will always feed water. In the old-style cage the bottle would be on its side, and when half empty would not feed water, as will be seen by the middle cages in Fig. 1. The new-style cages with solid top, bottom, and ends braced with the transverse fences and the cross-cleats over the wire cloth on the two sides, make a very strong cage—one that might stand the rough handling of parcel post, providing bees could be shipped that way. The water-bottle in the cage of the half-pound and the five-pound size is stationed in the center of the cage. See Figs. 3 and 6. In the one and two pound sizes it is placed at one side. See Figs. 2, 4, 5.

In Figs. 4, 5, 6 will be noticed little cake-tins placed on top of the cage at one or both ends. These are filled with ordinary queen-cage candy made by mixing powdered sugar and honey that has been thoroughly sterilized, and then kneaded into a stiff dough. These cake-tins are filled level full of the candy, inverted, and nailed over a longitudinal slit in the top. See Fig. 2. The larger-sized cages require, of course, more candy and larger containers, and all of them require water in hot weather.

HOW TO PUT BEES INTO THE CAGES.

There has been a raft of inquiries as to *how* we get the bees into these pound cages. This is a very simple matter. Just suppose we are going to put up a two-pound package of bees. We take a package of suitable size, put it on a pair of scales having an adjustable dial to take off the tare. Then we set the pointer back to zero. We now open a hive which the records show is capable of filling this order, and yet leave sufficient bees to take care of the brood. We next find the frame the queen is on, and

FIG. 4.—Two-pound size, new style, without combs.

set it down beside the hive. We now take a position as shown in Fig. 7, with a specially constructed funnel having a large oblong top and a small contracted opening at the bottom just large enough to insert in one of the round holes in the top of the cage. The frame is inserted in the funnel as shown, and given one quick shake, dislodging four-fifths of the bees. As the inside of the funnel is smooth, the bees slide right down easily into the cage. Another frame is shaken in like manner; and when the pointer on the scales registers two pounds, exclusive of the tare taken off, the

FIG. 5.—Three-pound size, new style, without combs.

FIG. 6.—Five-pound size.

funnel is removed. If bees are gathering honey freely we add 25 per cent to their weight so as to give full measure. After the bees are all shaken into the cage, the last operation is to pick the queen off the comb that has been set aside, and gently drop her among her subjects in the cage. But it very often happens in the early part of the season that it is better to fill an order from four or five different hives. To take two, three, or even only one pound of bees from a colony in the spring is a severe drain on them. Sometimes we fill a package from three or four different hives. That, of course, means we will have in the cage as many different lots of bees.

How about the queen? In nine cases out of ten any queen from any hive may be dropped into such a heterogeneous mass of bees, and be accepted without any further trouble; but because of that one failure out of ten we now make it a rule to use a virgin-introducing cage with a plug of candy in it, and into this we put the queen. The introducing-cage is secured to the wooden cap that covers the filling hole. In four or five hours the bees will be ready to accept their queen—that is to say, they eat out the candy and release her.

So far we have been able to ship bees during the hottest weather in summer, providing we use water-bottles properly arranged

so that they will feed water during the entire trip. We have already published reports of how we have shipped bees successfully to Oregon, Florida, Maine, and many other points, with the loss of scarcely a bee.* But it is exceedingly important that the candy be made just right. A candy that is too soft will run down and daub the bees. A candy that is too hard the bees can not eat. It must be just right. We make up a batch of candy about a month before we expect to use it. We let it stand in a warm room; and if it begins to spread in the pan or on the molding-board, after standing two weeks in warm weather, more powdered sugar is kneaded in. If, after a week or ten days, it seems to be soft and moist so that it can be indented by a pressure of the finger, and yet will hold its position without "running" on the molding-board, it is then fit to use. A word about the sugar. Be sure to get powdered sugar without starch in it.

We anticipate that the pound packages of bees we illustrate, or those embodying these principles, will be a nice business for

* We shipped one three-pound package of bees to Guelph, Canada, last winter, when the temperature was nearly down to zero. About one-third were dead on arrival. The expressman probably felt sorry for them, and set them against a steam-radiator. We don't believe the cold killed the one-third that were dead.

FIG. 7.—Method of putting bees in the cages.

beekeepers all over the country. It will make an interchange of bees possible from one locality to another without danger of transmitting disease, and at the same time reduce the cost of express charges down to a mere trifle. It will also make it possible for the extensive beekeeper to ship a thousand colonies in a carload from the South to the North as against only 250 colonies on combs in hives. But do not let any one be foolish enough to try to ship a carload of bees in pound packages until the thing has been tried out more thoroughly in small express shipments. We expect to send fifteen or twenty colonies to Des Moines in three and five pound packages, as shown in Fig. 6. The express on these will be about one-fourth what it would be on full colonies. The bees will be shaken on frames of foundation toward night. The entrances will be closed with perforated zinc. Now right here is a danger. Where possible, bees in pound packages should be let loose on a frame of unsealed brood. Where one already has bees in the yard, he can secure his brood from other colonies; but in the case of a beginner who has absolutely no

bees, he will have to let them loose on foundation, and watch them carefully next day, as they may swarm out. Of course, bees that are let loose on foundation should be fed a thin syrup.

Another question here has been often asked—"How are you going to get the bees out of the cage on the frames?" Smoke the bees a trifle, and pry off the cleats on the side; remove the wire cloth, and lay the cage flatwise down on the frames. Put on an extra super, then the cover. In two hours the bees will come down on to the combs. If the bees have a frame of honey, or, better, one of unsealed brood, they will go down immediately. If only bare foundation, they will show a tendency to cling to their cage several hours, when they will gradually work downward.

Now one more caution. Do not try to ship bees by parcel post. It is forbidden by the regulations, and under present conditions it will not be possible to get the bees through alive in the ordinary parcel-post mail-bags. So do not try it under any conditions.

These special cages may be obtained of the dealers. But better not try to make up your own cages, as your first experiment may be a light fragile affair that will not stand ordinary usage in the express car.

We have so far omitted to say that, along with every package, is a live-bee tag with instructions to the express man to keep the bees out of the sun, away from steam-pipes, and from exposure to unnecessary cold.

BEEKEEPING IN SOUTH RUSSIA

BY AUGUST DE MALACHOWSKI

I am sending you some photos* of my hives in Russia, and a drawing of one of my "Elita" hives, as well as my Eureka feed-trough. I shall not dwell long on the description of my hives, because the drawing shows the same sufficiently. There only remains for me to say that the hives are constructed of spruce, one inch thick. These hives have been giving me complete satisfaction for some years; and even this year, which was very bad for honey-making, and during which the bees did not make cells in the Dadant-Blatt hives, my Elita were full of honey, and I obtained more than 55 lbs. of honey.

My frames are also another peculiarity. The interior size of the brood-frame is $8\frac{1}{2}$ inches wide by 17 high; and for the super,

* One of the photographs sent is used as our cover picture for this issue.—Ed.

$8\frac{1}{2} \times 8\frac{1}{2}$ inches. I arrange so as to put into the large frame two smaller ones that fit into the super. Once my frame is divided in two, I can at any moment remove the contents of the frames or transport to the super a part of the honey, put the brood-combs below, etc. I make these interior frames in the sectional style, of boards about $\frac{1}{4}$ inch thick.

I have many of these frames ready with wax foundation, and I use them even with my Elita hives, or with my brick hives when needed. This is extremely practical in apiculture, because, having these frames in the super filled with honey, after making a springtime visit and noting that the bees are short of honey, nothing is easier than to give them one of these surplus combs of honey.

The engravings show that I have some brick hives. There are four colonies in each house. Each colony has a wooden hive covered on two sides with moss or fine straw, and entirely covered by some boards in order that the mice may not enter. These hives are very practical, because the bees winter in them very well on account of the even temperature.

All my hives without exception, even the Dadant-Blatt, are furnished with my Eureka feed-troughs, which have given me entire satisfaction, and are so practical that one can feed the colonies at any time without opening the hives. I fill a bottle, equip-

The old type of hive equipped with box feeder.

Latest model of Malachowski's hive, "Elita," with "Eureka" feeder.

ped with a small aluminum tube, with syrup or diluted honey. If it is cold weather I heat it a little; and when I turn the bottle upside down in the trough I can then see in a few moments that the bees are quickly eating the honey by the bubbles of air which come up. This is very practical, especially in the spring time, in order to stimulate brood-rearing. I can feed an apiary with 100 hives in half an hour at the most.

I make my feeders in the house; and, moreover, if the hive is thick or has double walls I only lengthen the tube. As there are only two small openings to allow the syrup to pass through, the bees can not enter into the tube.

This is the feeder that I recommend, especially to my co-workers in apiculture in America; and by using the same you will find that you will be very well satisfied.

Odessa, Russia.

BEES AND THE PARCEL POST

BY R. W. COBB

In GLEANINGS for January 15 and February 15 the possibilities of shipping bees by parcel post in one-pound packages or cages is commented upon by the editor. It is a very interesting subject to me, as my occupation for the past ten years has been

Portion of apiary of A. de Malachowski, in South Russia. In every brick tenement hive there are four colonies.

One of the first models of Malachowski's hive, "Elita."

that of a railway postal clerk. I have given this much thought ever since The A. I. Root Co. shipped the two carloads of bees from Florida last spring. Excellent time for freight service was made; but had there been a method for shipping by parcel post the expense would have been cut tremendously, and the time on the road materially lessened. I have always been in favor of the parcel-post system, and am more so since its inception; but having seen so much of the practical side of shipping packages of all descriptions by mail, it must be admitted that we beekeepers, with our present equipment, are far from being prepared to reap any advantages in this line from parcel post.

Before any attempt is made to ship a nucleus or even a half-pound or a one-pound package of bees by mail, provision should be made for a receptacle to combine four qualities. First, strength; second, ventilation; third, protection to the bees; fourth, protection to those who handle it. This means we can not use an ordinary wire cage, such as the express companies are now accepting. Neither can we use a package such as Mr. J. A. Kreighbaum describes, p. 132, Feb. 15. While he has partly solved the ventilation problem by providing the air-space between the two

walls, he has neglected to protect both ends and both sides. I infer from his description that a board was placed over the top, and a piece of heavy felt on the bottom; but no protection is afforded either end or either side against the possibility of a hole being made through the two walls of wire cloth. There is his weak point. While ninety-nine cages like that will travel safely by mail, the one hundredth one will meet with an accident and cause untold trouble.

But few people realize the great number of times a piece of mail is handled from the time of mailing until reaching destination, and the strain necessarily imposed upon it. In the case of bees, each handling means an additional jar and a consequent ruffling of their tempers, and the liability of the postal employee being stung.

The postal laws and regulations require all mail to be dispatched from postoffices to trains and *vice versa* in mail-sacks which are closed tightly to guard against any loss of mail. Hence the instant a parcel is dropped into a mail-sack its identity is lost until the sack is reopened. During this time the package of bees will be in various positions in the same sack. For instance, at one time it may be right side up; again, it may be on its side, and still later it may

be upside down. With the express companies it would not be out of sight at any time, but in the same position *all* the time. The above-mentioned conditions will hold, no matter how many caution or fragile notices the packages may be endorsed with. I can now bring out my point by a single illustration, somewhat lengthy, but showing practically the exact number of times a package would be handled in transit.

We will assume that The A. I. Root Co. at Medina, Ohio, mailed a package of bees to go by parcel post to Mr. Doolittle, at Borodino, N. Y. The postmaster at Medina places the bees in a sack with other second, third, and fourth class matter, and dispatches it by wagon to a railroad depot at Medina. It is then taken from the wagon at the depot and placed on a truck, and wheeled across the station platform and put on the train, where the postal clerk opens it and makes proper separation of the mail. The bees are then placed in a sack which is labeled "New York," along with all other mail for that State.

At Cleveland the sack is taken off this train and placed on a truck with many others, and wheeled across the station platform to a wagon awaiting the arrival of this train. It is then placed in the wagon and transferred across the city to the depot of

the L. S. & M. S. railroad. Here the contents of the wagon are sorted, and each individual sack placed on a truck with other sacks for the same State, and then wheeled to the car of the train into which they are loaded. As the sacks are taken into the car by the men, they are placed in a pile until each individual sack can be sorted. That is, all the sacks labeled "N. Y. State" are placed in one pile, and those labeled "Massachusetts" in another pile, and so on. In the New York pile there may be anywhere from ten to forty sacks full of mail. The sack containing the bees may be on the top, in the middle, or perhaps at the bottom of the pile. The next procedure is, distributing these sacks—that is, dispatching each individual piece of mail to its proper destination. This time the sack containing the bees is carried from the pile in which it was placed when taken aboard the train, and contents dumped on a table, so as to be readily accessible to the postal clerk, who places the bees in a sack labeled "Syracuse & Rochester R. P. O." (railway postoffice). Before arrival at Syracuse the sack is taken out of the rack in which it was suspended, and placed in a pile of mail to be put off at that point. It is then loaded on to another truck and wheeled across the depot platform to the "Syracuse and Rochester"

train, where it is taken into the car and goes through the same process of being piled in with several other sacks which are to be distributed on this train. Here the bees are placed in a sack of mail for Borodino, and eventually put off at that place and carted to the postoffice, where the sack is opened, and bees delivered to Mr. Doo-little.

During this time the bees have been on their journey less than fifteen hours, and have been handled a great many times; yet only three persons knew the contents of the mail-sacks. Mr. Kreighbaum's receptacle practically requires that every person handling a sack of mail know its contents—a condition which is impossible.

I think from the foregoing that any one can understand why the receptacle should be firm, strong, and well built. The strain which has been imposed upon it has been enormous. Should it be unfortunate enough to have had an extra-heavy weight placed upon it, causing some portion to spring, or a hole have been made, allowing the bees their freedom, a great many stings would be received by those handling it. Should any of the government employees be stung, a ruling would soon emanate from the Postoffice Department at Washington, barring bees from the mails entirely. This would place us in the same predicament we were in about thirty years ago. It is not hard to imagine how serious an injury to apiculture this would be. I have reread the article in GLEANINGS of March, 1880, page 106, and must say that the conditions are just the same to-day regarding the essential qualities of a mailing-cage.

We must bear in mind that it is now allowable to ship such things as iron and steel castings, not exceeding ten pounds in weight, by parcel post. For my own part I would not care to meet an infuriated bunch of bees which had just made the acquaintance of an iron casting, killing and maiming a portion of them. Consider, then, the predicament of the postal employee who has never seen nor heard of a veil or smoker. I well remember the day when, still a small boy, I was returning home on the train with my father and mother after a day spent at The A. I. Root Co., in Medina. Father had purchased a pound package of bees which we were carrying home, and, boylike, attracted by the bees crawling on the screen, I undertook to feel of them, which resulted in my receiving a painful sting. My cries furnished entertainment for the occupants of the entire car.

As the postal laws and regulations now stand, I do not think a package of bees of

any size other than these in which we have sent queens is mailable. Section 496, paragraph 7, of the Postal Laws and Regulations, plainly states that "Queen-bees and their attendant bees" are admissible to the mails. A pound or a half-pound package would not enter into the spirit of this law. I might add that queen-bees and their attendant bees and the Australian ladybird are the only live "stock" admissible to the mails. I can hear some people saying, "Oh! we have received such and such a live thing by mail." That is true, and the explanation is easy. The postmaster at the office of mailing was ignorant of the Postal Laws and Regulations or it would have been withdrawn from the mail and returned to the sender.

By all means, before we jeopardize the privilege we now have of mailing queens, let us perfect a suitable receptacle for shipping bees, and then have it approved by the postal officials at Washington.

Lakewood, Ohio.

[The present regulations with regard to packages by parcel post are such that it would be impossible to ship bees in that manner, and get them through alive, even though the postal regulations did permit it. If they are ever to be sent by parcel post it would never do to put them in a mail-sack as we do the queen-bees and their attendants. They would smother to death. A large number of bees, say half a pound, a pound, two pounds, three pounds, or even five pounds, would need to have a large amount of air; and during hot weather they would smother to death in a very few minutes in an ordinary closed mail-sack. If the time ever comes when we can send pounds of bees by mail there will have to be some regulation that will permit packages of bees to be left outside of the mail-sacks. Whether Uncle Sam will ever make such discrimination in favor of bees is doubtful. If the time ever comes when it is permissible to send live poultry by parcel post, then we might be able to secure a ruling that would permit live bees in quantities of half a pound, pound, two pounds, or three pounds, to go in that manner.—Ed.]

Treatment of Laying Worker Colony

P. C. Chadwick, referring to page 75, Feb. 1, will there not be bloodshed in the laying-worker colony, now containing the frame of brood, on the return of the *flying bees* of the strong colony, on whose stand the former colony is now placed? I presume you also mean that the queen of the colony which is now placed on the stand of the laying-worker colony has to be caged for a time to prevent molestation from the bees of the latter.

JOHN ELIAS JAMES.

IS ALFALFA POLLINATED BY BEES?

Some Interesting Points in the Discussion

The following article appeared originally in the *Dakota Farmer*, on page 61, by A. O. Stevens, of the North Dakota Agricultural College. One of our subscribers, Mr. Jess Dalton, questions the correctness of Mr. Stevens' statements, and desires to make a reply. In order that the reader may better understand it, we are publishing this article entire.—ED.

BEES AND THE ALFALFA SEED CROP.

In the December 15th issue of *The Dakota Farmer* appeared an article referring to the value of the honeybee as a pollinator of the alfalfa flowers. The article in question is quoted for the most part from *The Country Gentleman*, and begins thus:

"Very few data are at hand relative to the value of insects in the production of a seed crop." This is quite true; but it is also true that most of the discussions on the subject appear to have been written without a knowledge of the data which are available. Nearly half a century ago it was made known by men of no less authority than Mueller and Henslow that the bee visits the alfalfa flowers without effecting pollination.

Far be it from the writer to discourage the bee industry, especially in connection with such a valuable honey-plant; but the subject has been treated so frequently without due regard to the facts that it seems desirable to present a brief survey of the situation.

In order to understand the conditions it will be necessary to call attention to the flower structure. The stamens and pistil of each flower are enclosed by the two inner petals (which are united along the lower edge, and are known as the "keel"). The pollen-bearing portions are thus entirely concealed, and are not exposed to visiting insects. When, however, a pressure is applied inward and downward upon the keel petals, a certain tension is released, which causes the stamens to snap upward with considerable force. This may be readily observed by using a toothpick or other pointed object. If this pressure is applied by a bee, the pistil (which is enclosed by the united filaments of the stamens) is thrust against the insect's body, and pollen is rubbed upon the insect by the stamens. As the pistil projects slightly beyond the stamens, it is likely to receive first the pollen left by a flower previously visited.

The bee, however, rarely inserts its tongue at this part of the flower, but thrusts it between the two outer petals, leaving the stamens undisturbed. The bees are easily observed, and any one may satisfy himself on this point. In one trial by the writer at Manhattan, Kansas, in 1909, the visits made to 584 flowers were observed in about an hour. Of these, only nine were tripped by the bees.

Concerning the effectiveness of other insects, practically no data of value are available so far as is known to the writer. The insects usually mentioned are butterflies, bumblebees, and "wild bees." The butterflies are common visitors, but seem to be of very little if any value. Bumblebees, according to a few observations made the past summer, often reach the nectar in the same way as the honeybees, although they seem to trip the flower more frequently.

The wild bees are practically unknown except to those who have given them special study. Every locality with an average number of native plants has one or two hundred different species of these bees, so that the expression, "where insect life is scarce," is hardly applicable to many cases. By no means all of these are adapted to such a flower as that of alfalfa. In the limited observations which the writer has been able to make, the only bees which tripped the flowers regularly were the leaf-cutters (*Megachile*). These and their near relatives

may be distinguished by the fact that the females collect pollen on the under side of the abdomen. The species chiefly observed is nearly as large as the honeybee, and with a tongue of nearly equal length. Another common one is about one-half larger than the honeybee, and with a longer tongue. On the whole these bees seem better adapted than nearly all the others to this plant. The species are very numerous, and are found over nearly all the world.

Now that the probability of insect pollination has been reviewed, the necessity of it needs a little attention. To quote again the previous article: "At the Kansas Experiment Station, alfalfa plants covered with a wire netting * * made no seed, whereas those plants that were adjacent but uncovered were filled with seed-pods." This reference seems to be to bulletin No. 155 where some such statement is made, but without details or data. Another bulletin of the same station (No. 151) presents unmistakable evidence to the contrary. A careful study of the data presented seems to indicate that, while insects may be important, there are some unknown factors, physiological or otherwise, of greater consequence. All of the plants covered with wire cages, and left undisturbed, produced seed, but at greatly varying rates; those having but little, also being light producers in the open field. If a calculation be made from the plant producing the most, a ton of green plants would yield 8½ pounds of seed. On the same basis for five plants which were divided, half of each plant being covered and hand-pollinated, the other half permitted to be insect-pollinated, the average would be 10.4 pounds for the hand-pollinated, and 11.8 pounds for the insect-pollinated. Again, from twenty-six plants, hand-pollinated, the average would be 5.8 pounds, and the highest 68 pounds, per ton of fresh plants. There was also a great variation in the per cent of flowers producing seed, and this did not correspond to the amount of seed per weight of plant.

Burkill, who investigated the subject quite carefully in England, did not secure seed from untripped flowers unless he pinched or rubbed the tip of the pistil. He seems to have inferred that the striking of the pistil against the insect's body was an essential point. It is well known that injuries to plants often induce fruitfulness, and perhaps the dragging of an alfalfa-field may act in this way in addition to tripping the flowers.

This was submitted to Mr. J. H. Lovell, of Waldoboro, Maine, whom we regard as the best authority on the pollination of plants by insects, perhaps, in the United States. He has done a vast amount of field work in investigating the subject of pollination. He is an entomologist, a botanist, and at the same time a beekeeper. We have submitted this to him for his examination, asking that he give us his views for publication. At the same time, we suggested that, when a plant has nectar, color, and odor, it has these properties for a purpose—to invite the visitation of insects—bees in particular. Mr. Lovell's reply is interesting and valuable, and we think it shows conclusively that bees, so far from being of little or no value in pollinating the blossoms of alfalfa, are a very important factor in increasing the seed crop. We will now let Mr. Lovell speak for himself:

Dear Mr. Root:—Your favor of the 13th instant is at hand, with enclosures as stated.

I am sending a brief account of about all that is known in regard to the pollination of alfalfa up to the present time. Last summer I cultivated a bed of this valuable fodder plant in my garden for the purpose of studying the relation of the flowers to insects; but, unfortunately, the season was very wet, the leaves rusted badly, and few flowers were produced.

It is well established by numerous observations that honeybees do not usually pollinate the flowers of alfalfa, but obtain the nectar through a hole in the side of the flower. That is, there is an imperfection in the structure of the flowers which the keen observation of the honeybee quickly discovers. It can extract the nectar more easily through this crevice than in the normal way. So far as beekeepers are concerned this is an advantage, since a bee requires less time to gather its load of nectar.

The flowers are often pollinated by bumblebees, though they, too, sometimes pilfer the nectar; by butterflies and by leaf-cutting and mason bees. The two last-named genera, which are provided with a pollen-brush on the under side of the abdomen, are better adapted for this purpose than the honeybee. There are many species of the leaf-cutting bees (*Megachile*), and in certain localities they are so abundant as to defoliate trees. So far more than 24 species of wild bees have been observed on the flowers, besides many butterflies, flies, and beetles. Just how many are efficient pollinators is not known. Many are not. In South America the flowers of alfalfa are often visited by small birds resembling hummingbirds, called honey-suckers.

A single normal visit is sufficient to effect pollination, and all further visits are useless. The flowers are known as explosive flowers. The anthers and stigma are held in the keel under tension. When a bee presses down the wings and keel it pulls, says Burkill, two triggers and fires off the flower—that is, the anthers and stigma fly forcibly upward and out of the keel, and the pollen is thrown against the body of the bee—a kind of catapult. The stigma is a little in advance of the anthers, and strikes the pollen-brush of the insect first. Both of these organs then move upward against the standard, where they are out of the way and do not again come in contact with insects.

The flower should now cease secreting nectar, since nothing is gained by the attraction of further visits from insects; but here we meet with another imperfection, for the secretion continues. Insects, therefore, continue to visit the exploded flowers,

when it would be of much greater advantage to the plant species for them to visit exclusively flowers not yet pollinated.

The flowers can not be pollinated by the wind; and, according to Urban and Burkill, they do not possess the power of self-fertilization, even when the stigma is surrounded by pollen. According to the latter observer, the stigma does not become receptive in the absence of insects until it has been rubbed or scratched by a brush or a needle. The reason for this is, I believe, largely mechanical rather than physiological. The stigma is covered with papillæ, which may sometimes prevent the pollen grains coming sufficiently near to receive the stimulus necessary to excite germination. But when they are rubbed between the papillæ by the pollen-brush on the bee, germination promptly follows. A slight change in the conditions, which probably often occurs, as greater sensitiveness on the part of the stigma, or greater pressure, would induce self-pollination. Henslow records that plants he protected yielded more seed than those left unprotected. In cold wet weather the flowers wither without exploding. Where the vines are cut before they bloom, as is the increasing practice in the West, it is, of course, of no consequence whether the flowers are pollinated or not. When alfalfa is cultivated for its seed, there is, so far as I know, no complaint that the flowers are sterile.

Mr. Stevens says that he saw 584 visits made by "bees" (not by one bee) in about an hour, and that in nine instances the flowers were exploded or "tripped." It is probable that many of these flowers were already exploded. This observation is of considerable interest in showing that the honeybee is of real importance in the pollination of alfalfa; and it is to be regretted that he did not give the matter more attention, for Mueller never once saw honeybees visit the flowers legitimately. A man could hardly watch closely for an hour more than five square feet; and if in this area there were nine cases of pollination, then at the same rate there would be about 8000 on an acre of alfalfa, or in ten hours 80,000 flowers pollinated. It is to be remembered that only one visit is required, and that subsequent visits are valueless. Of course, such an estimate based on a single observation is to be taken with great latitude; but it indicates that the honeybee is of more significance in the pollination of this species than has been commonly supposed.

Even if the flowers of alfalfa can not fertilize themselves in Europe it does not follow that this is true in western North America. There are well-known instances

of flowers which, in one climate are infertile, becoming fertile in another. It has, moreover, been asserted that in Germany the flowers have the power of self-fertilization. In experiments made at the Kansas Experiment Station, according to Mr. Stevens, plants covered with wire cages produced seed, though at greatly varying rates. But this difference seems to have been due to the character of the plants. There seems, then, good reason to believe that in America, at least in the western States, the flowers can produce seed, even in the absence of insects.

Mr. Stevens' article is in the main correct so far as it goes, but he seems not to be familiar with the mechanism of pollination, nor, as he admits, with the wild bees. The suggestion that there are some unknown factors which are more important than insects or self-pollination, if he refers to any thing more than weather or climate, is purely imaginary, and is an unnecessary supposition. The fact that the bees made so many visits in an hour would indicate that the flowers contained little or no nectar. It would require only a few seconds for a bee to thrust its tongue into the side of a flower, remove it, and pass to another flower. It would be an easy matter to count ten visits per minute, which would give 600 for an hour.

You are entirely correct in supposing that the possession of nectar, color, and odor are invitations given by flowers to insects; but the conditions may be modified when the flower is *not* cultivated in its natural habitat by the characteristics of the insects, etc.

JOHN H. LOVELL.

Waldoboro, Maine.

NATURAL WINDBREAKS THE BEST; BUT THEY CAN NOT ALWAYS BE SECURED

BY R. F. HOLTERMANN

On page 181, March 15, it appears to me that Mr. Byer assumes that I said something which I have no intention of claiming. I have not compared the value of fences and natural shelter. There is no comparison, in my estimation. Natural shelter is desirable—very much so—and I aim to have it wherever I can; but, after all, the cases where sufficient natural shelter can be secured are rare. A great many people have to keep bees in certain positions from necessity, not wish, if they keep them at all; and the majority of these are *not* sufficiently sheltered. There are few locations wherein bees are now kept, and where we have a solid winter, to which I would not add a

fence as before described. A great many may not agree with me about this matter; but I have tested it sufficiently for my own satisfaction.

Our bees have wintered well; but some, I find, have starved owing to the open winter and resultant activity. To date, the least loss in an apiary is none (is that an Irish bull?), and the greatest, ten; the latter mostly starved. This latter was in the most exposed location, so far as natural protection is concerned, but it has a fence about it. Would the loss have been less if the fence had been down? I want *both* natural and fence protection.

QUEENLESS COLONIES GATHERING POLLEN,
AND STORING IT IN CELLS FORMERLY
OCCUPIED BY BROOD.

R. O. Martin, p. 180, Mar. 15, takes little stock in my argument as to queenless colonies gathering pollen because of the amount of pollen I find in the comb. Let me say again that my own eyesight, seeing the bees bring in pollen, is sufficient; but, more, the pollen stored in the combs is sufficient also. When I find pollen not in the cells about the comb, which is the natural position of brood, but all through the comb, not individual cells, but many, I am forced to the conclusion that the bees gathered it after the brood hatched from the comb. More, the distinction in this respect is so clear that I have pointed it out time and again (having the combs side by side) to young men learning the business. It is more than likely that, when I get among the bees, I shall find such combs; and if I do I will try to have a photograph taken of them, and send them to GLEANINGS.

If the bees can gather pollen after they are queenless and the brood hatched, then they place pollen in sufficient quantities where brood would otherwise be, it clearly indicates that this pollen was gathered after the colony was queenless; and the appearance of these combs is a direct contrast to colonies in the same apiary not queenless. In a locality scarce of pollen, these indications may not be so marked; but that has nothing to do with the question as to whether queenless colonies gather or do not gather pollen.

Brantford, Canada.

A Correction

In your editorial, p. 105, Feb. 15, you say, "while timothy hay, the kind referred to." By referring to my communication you will notice the kind of hay used by me was not mentioned, but *clover* hay, *not timothy*, was always used, as it is more springy or resilient—at least this is my experience.

Victoria, B. C.

E. E. ROBINSON.

Heads of Grain from Different Fields

The Robber-cloth Perfected

No doubt all users of the present robber-cloth have realized its lack of effectiveness in fully covering the open hive top at all stages of operations. I am pleased to present herewith for the benefit of other beekeepers, my original idea of a perfected robber-cloth as an aid to advanced bee culture.

By joining two cloths by means of a light stiff frame so proportioned as to leave a space of about $2\frac{3}{4}$ inches between the cloths, several new advantages are gained, and the duplex arrangement becomes positively effective in guarding the open hive top while convenient access to the frames is actually facilitated.

Fig. 1.

Fig. 2.

The drawings show the device so clearly that no description is really needed. In practical use the frame A is placed above the particular frame to be lifted, with each cloth lying flat away from the frame A. When it is desired to close the gap E, the frame A is grasped at either end by the finger and thumb,

and turned over, using either side as the axis. This movement draws the edge of one cloth over the other, thereby overlapping and closing the gap E. The reverse movement of the frame A again opens the gap almost instantly.

The edge of each cloth opposite the frame A is weighted somewhat by a hard-wood stick, an iron rod, or in any suitable way, so as to hold the cloth flat against the wind when the frame is turned. This frame A is best made from $\frac{1}{2}$ -inch dowels and two pieces of galvanized sheet iron. Three $\frac{1}{2}$ -in. holes are punched in each end of the iron pieces, through which to drive the clinching nails. The dowels are slit with a saw (a fine circular saw does it best),

but do not cut the pieces entirely apart until later. The reason will be evident when the job is further under way. Use flat-head thin wire nails just long enough to prick through. Place the selvage of the cloth next to the gap E, and hem all exposed raw edges. Proportion the cloths so that each will be an effectual cover by itself, large enough so that careful adjustment will not be necessary. An eight-frame cloth could not be used on a ten-frame hive.

This perfected robber-cloth is particularly useful in treating foul brood; but care must be taken afterward to sterilize it thoroughly before using again around healthy colonies. Two perfected robber-cloths are needed in practice, one for the hive being operated, and another for the hive to or from which frames are being taken. The perfection of this duplex arrangement is best appreciated under practical use. Any one is at liberty to make and use this new robber cloth, and it is my hope that it will be tried extensively, and that my expectations for it may prove well founded.

Spaces with Packing Material vs. Dead-air Spaces

It is generally conceded by carpenters that a dead-air space is warmer than a solid wall. I have no reason to doubt that it is; but I want the proof. I think it is proved that, with brick, stone, and concrete blocks, a dead-air space is warmer in winter than a solid wall; but that is *real* dead air. I mean that there is no air that can get through the cement blocks from the outside as I am sure it does through wood. A thermos bottle has the air pumped out, and contains only a vacuum, if I understand correctly. The same bottle with *dead* air would not be as good by a half—that is, to exclude either heat or cold for a long time. The thickness must be considered. A brick, stone, or cement wall with a dead-air space would be all the way from six inches to two feet

thick; but we can hardly compare the above-mentioned material with wood, straw, cork, and chaff. What I want to get at is a double-walled hive not too large, yet large enough to give the best of protection. Now, how to find out how much difference there is between one, two, three, four, five, or ten inches of air space or packing material—the difference between thick and thin outside walls, and also the difference between different kinds of packing material of different thickness.

EDWARD HASSINGER, JR.

Greenville, Wis., Feb. 17.

[Some twenty or more years ago some quite exhaustive experiments were made. It was then shown very conclusively that a dead-air space, so called, was not nearly as good as a space packed with packing material such as chaff, planer-shavings, forest leaves, or any material that will break up the circulation of air. The trouble with the so-called dead-air space is that the air is *not* dead. It comes in contact with the outside wall, which is cold, circulates over to the inner wall, which is warm, making a constant circulation carrying the cold air from the outside to the inner wall, thus making a continuous circulation. Now, the purpose of the packing material is to *break up* this circulation, so that the air *can not circulate*. There will then be a cold layer of packing material next to the outside wall, and a warm layer next to the inside wall. This matter has been tested very carefully by the builders of engines, who place packing material like asbestos between the outer and inner walls of the cylinders. The matter has been tested so thoroughly and carefully by scientific men that we do not believe there is any question that a given space containing packing-material is a great deal better than the so-called dead-air space. But a dead-air space in building-blocks is a good deal better than solid blocks, for the simple reason that a stone block will carry the cold clear through into the inner wall, where with the dead-air space the cold is not carried quite so quickly. A dead-air space is better than nothing; but if a building-block had packing material placed in those spaces it would make the building much warmer.

We don't know whether a solid block of wood would be colder than a hollow wooden block with dead air.

In the case of a thermos bottle, there is, as you say, no air between the walls, and, of course, there can be no circulation to cool the inner wall.—Ed.]

Cayuga County Convention

The annual meeting of the Cayuga Co. Beekeepers' Society, March 12, was well attended. Several speakers from abroad were present, and added interest to the occasion.

Mr. Irving Kenyon, of Camillus, N. Y., Secretary of the New York State Beekeepers' Association, gave a brief review of the fall meeting of that association, bringing out the points of interest. He also gave an address on the production of extracted honey, explaining in detail his own elaborate method, in the course of which he exhibited a device of his own invention for fastening foundation in the sections for comb honey; also an electric contrivance for imbedding wire into the foundation, and a very ingenious and rapid method of fastening the wire into the shallow frames. He uses the steam-heated uncapping-knife, and likes it very much.

Mr. Kenyon has been so successful in producing extracted honey and in marketing it at a fancy price, that it was a surprise when he incidentally remarked that he was going back to the production of comb honey.

The address of Charles Stewart, of Johnstown, N. Y., "What can beekeepers do to help the inspector?" was very practical and pointed. He said we quarantine apiaries as doctors do their patients;

but the inspector is at a disadvantage, as his patients can fly, while the doctor's can not. For this reason it is hardly fair to expect the inspector to stamp out contagious diseases in a year or so when doctors fail to do so. He called attention to the fact that the foul-brood diseases are more virulent at the start, and gradually become milder and less to be feared, as in the case of smallpox, etc., with human beings. He considered the Italian bees most immune, or best able to resist the disease, and advised Italianizing, even before the disease gets a start. One can help the inspector by writing to him on the least suspicion of any trouble in the yard, and not waiting for the inspector to look him up.

Mr. Stewart advised getting rid of old combs by melting into wax, and using full sheets of foundation. It is a paying investment, as the bees gnaw away a good part of the old combs, and the wax is thus lost.

The address of S. D. House, on hives and fixtures, was an eloquent plea for the use of the sectional hive with a short shallow frame. When one or two sections are added, the hive presents the form of a cube, which is the condition nearest to nature. If his arguments failed to convince his hearers that his hive was the best for all purposes and places, he *did* impress all with the fact that his success as a comb-honey producer is indisputable evidence that his hive is the best for his own locality under his skillful manipulation.

The convention adjourned at five o'clock, the same officers holding over.

Ithaca, N. Y.

E. D. DRESSER.

Kansas State Convention

The tenth annual meeting of the Kansas State Beekeepers' Association was held in the Commercial Club rooms, and was largely attended on February 4.

The address of welcome and transaction of reports of last year's meeting took up the greater part of the time.

On February 5 there was a large attendance at both meetings. Talks were given by Prof. George Dean and Prof. S. J. Hunter, both of which were highly appreciated by those present. Dr. G. Bohrer, of Lyons, Kansas, O. S. Mullin, of Holton, and Arthur Small, of Topeka, read a number of articles of interest to beekeepers.

The following officers were re-elected: President, P. R. Hobble, of Dodge City; Mrs. J. D. Smith, of Troy, Vice-president; O. A. Keene, of Topeka, Secretary and Treasurer.

The meeting adjourned with a unanimous vote of thanks to the Commercial Club, after which a half-hour was spent in visiting, then to the banquet-hall, where hot biscuits and honey were served.

O. A. KEENE, Sec.

Why Some Larvæ Are Not Sealed

I have been watching my bees and their brood for a number of years for foul brood; and by doing so I find during the breeding season lots of young larvæ that the bees fail to seal; and when I look again they are gone, but others still there again. They are left until they are perfect-looking bees, only a little small. Now, what do you call it? or why do they fail to seal them or take care of them? Is it on account of stores or cold chilly weather that they get chilled for them, and die before they can attend to them? I never could catch on to it right; but it should be prevented in the spring.

Richfield, Pa.

W. S. NEUMOND.

[During certain seasons of the year, and sometimes in certain particular colonies, we find what we call "bareheaded" brood—that is to say, the bees fail to cap over or seal up the young larvæ. This may remain for a considerable time. It indicates no bad condition; in fact, so little of it occurs

that we pay very little attention to it. But what you describe is evidently of a different character. It would indicate that it was starved or chilled brood. Sometimes there is a scarcity of pollen, and the young nurse bees are not able to feed the young larvæ properly. The result is that some of them die. It is removed, and then the queen lays again in these same cells.

A sudden cold spell coming on may cause the brood at the outer edges of the cluster of bees to become chilled and die. This will be subsequently removed by the bees; and, shortly after, other young larvæ may be found in their places.

The condition described does not indicate any disease; for if there were any thing of that character you would find it spreading to other hives; and not only other hives, but all through the colony where the first cells were found.

It might be possible, however, that it is a case of sacbrood, as recently described in GLEANINGS.—Ed.]

Cube Sugar for Winter Stores

This is my fourth winter's experience with bee-keeping far enough south to winter bees in the open, in single-walled hives, in Missouri, North Carolina, and now in Alabama. Until this winter, I just laid the cubes of sugar on top of the brood frames in a pyramid with a burlap sack over it, with burlap extending out over all four sides of the hive. I then put on a super which surrounded the sugar pyramid, then I filled in the vacant spaces in the super with dry leaves, and put on the cover.

The last two winters in Alabama my plan has been more simple. I removed two combs from the side of the hive, and filled the vacancy with cube sugar, as we had some "warm weather late in January. I examined all the colonies thus fed and found the bees piled all over the sugar, eating away at it as busy as hogs in a pit of corn.

Both you and Mr. Miller agree, p. 816, Dec. 15, that there is moisture in the hive. What about the bees having saliva to moisten their dry food? And how do they feed on hard candy? and I think even rock candy has been recommended for winter feed. The cube sugar will not melt nor run down on the bees if used above. And the bees will use it for brood-rearing in the spring. And, oh how nice and clean it is to feed, and how simple the problem! My experience covers territory only where it is warm enough to permit the bees to take a flight every few days. It is a boon for the South.

Later.—My weak colonies that were fed loaf sugar came through the winter safely. They not only wintered on it all right, but reared brood. Of course, when the bees could work outside I began feeding syrup.

Letohatchie, Ala.

W. N. RANDOLPH.

[While it is true that bees have a saliva, it should not be forgotten that, if they are to be confined for a period of three months on dry comb and dry cubes of sugar, without any means of getting water, there will not be very much saliva, for saliva is mainly water. But a colony in an ordinary winter repository will give off enough moisture so that the bees will have enough to make their "mouths water" when they approach a cube of dry sugar.—Ed.]

Early Spring Honey Saved for Winter Stores

In my locality we have a considerable early flow from fruit-bloom, dandelion, and willow, so that most colonies will nearly fill a shallow extracting-super from it. This early dark honey is a positive detriment when it becomes mixed with the clover, as generally happens. I have considered the plan of taking off this shallow super of early honey just before the clover flow, and reserving it for winter stores. The super could be set bodily on the hive

and left so for winter. Most of our wintering here is done on buckwheat honey, and I should like to know whether this fruit-bloom, dandelion, and willow honey, if well ripened and sealed, and finished off with buckwheat, would be safe for wintering. Buckwheat gives good results here for winter stores.

Stouffville, Ont., Feb. 15.

F. L. POLLOCK.

[We feel quite sure that the dark honey which you mention will be safe for winter stores. Whether it will be as satisfactory as stores made of sugar syrup is another question; but we rather doubt it.—Ed.]

A Package Wanted for Sending Honey by Parcel Post

We have watched GLEANINGS to see if any plan had been devised for sending honey by parcel post; but up to date, we have seen none mentioned. It would seem to us a package holding from one to 10 lbs. of honey, extracted or chunk, with a covering making it safe in the mail, could be produced profitably. We are told that honey is thus carried by post in Germany, and possibly ideas could be gotten from there.

In case of chunk honey the difficulty would be to secure an opening large enough to admit the honey, and that could be quickly and safely closed. The package ought also to be inexpensive; for while a few people will pay fancy prices they are the ones who use but little honey. The real consumers who take the bulk of the product are those who buy it as a food and not as a treat. So the price must be kept so as to be but little above what people are in the habit of paying for honey delivered. Of course, comb honey, as such, can hardly be sent in this way—at least unless the Postoffice Department handles it more carefully than the express companies do, which could hardly be expected.

THE ROCKY MOUNTAIN BEE CO.

Forsyth, Mont., Jan. 26.

[See answer to this question in the editorial department, this issue.—Ed.]

Growing Alfalfa at High Altitudes

Is it possible that bees do not work on alfalfa in high altitudes? I failed to see one bee visiting it at this point. This town of Portales is in a wide valley, and the altitude is nearly 4000 feet. If any readers of GLEANINGS have had experience in this I should like to hear from them. I fear this is a poor place for beekeeping.

Portales, N. Mex., March 2.

J. W. HOUTZ.

[We know that alfalfa grows readily in altitudes of five and six thousand feet high. We are not positive of its being grown in altitudes of seven and eight thousand, although perhaps some of our subscribers might be able to give us information on this point. But alfalfa grows very luxuriantly around Denver, and Denver is supposed to be about a mile above the level of the sea, so we see no reason why it could not be grown at an elevation of 4000 feet. Of course, alfalfa requires water; and at that elevation it might require irrigation to do well.—Ed.]

Cottonseed Meal as a Substitute for Pollen

Mrs. H. Millard, Feb. 15, page 131, recommends feeding aluminized sugar when pollen is scarce, in an experimental way. Let me suggest to her to try first feeding cottonseed meal. I have never read of any one trying the use of cottonseed meal as a substitute for pollen; but the editor suggests the use of rye meal as being more practical. It appears to me that, if rye meal were rich enough, cottonseed meal (which is much richer) would be better. By baiting your pan of cottonseed meal to attract the bees' attention, they will find it sooner.

Our Homes

A. I. ROOT

A BRIEF MENTION OF SOME OF THE GOOD MEN AND WOMEN WHO EXTENDED TO ME A HELPING HAND IN MY CHILDHOOD.

The article following was given in our local paper, the *Medina Gazette*, in answer to a request from the editor that I give him something in regard to my childhood. Before starting off for Florida I told our good people here that, in case a Home paper should not be on hand, as has happened several times during the winter, they should use this in place of it.

When I was nine or ten years old I climbed up to the top shelf of our bookcase and got hold of an old doctor book. I think the title was "Domestic Medicine" or something like that. The reason why I tackled the "doctor book" was because I had read and reread almost every thing available in that frugal home in Mogadore, Summit County, O. There was a family of seven children—three older and three younger than myself. I had read all the schoolbooks, for the younger and older ones, all the newspapers I could get hold of, the family almanac, and a good part of the dictionary. Well, the fore part of this old doctor book did not interest me particularly; but along toward the last part of it was an article on "electricity." It was almost my first glimpse of this strange force that has interested me more or less from that time to the present. This old book, among other things, told me how easily this wondrous power could be invoked by means of a roll of brimstone or a stick of sealingwax. At that early day (about 1850) what few letters were written were mostly sealed with wax. Later, wafers were used. By rubbing sealingwax or brimstone with a piece of warm woolen cloth, especially in frosty weather, I made my first acquaintance with electricity and electrical attraction and repulsion.

After I had read over and over all the doctor book had to tell me I questioned my father and mother, and everybody else, about electricity until I fear I was a nuisance. Finally an aunt of mine, who was attending "high school," informed me that her "philosophy book" told a good deal about it. It was then that I made my first acquaintance with "Parker's Natural Philosophy;" and over and over I scanned the pages that gave information in regard to this subtle element in nature. A little later on, in order to supplement the funds of our humble home we commenced to keep boarders. One of them was a schoolteacher, and another was a miller. Of course those two good men had to be "pumped dry," on electricity. Mr. Fairbanks, the school teacher, said I ought to study chemistry.

"What is chemistry?" I asked.

Well, this particular friend, whom I shall always remember, replied something like this:

"Why, my young friend, chemistry not only tells about electricity but discusses the nature of the elements of which this world is composed. I have an old chemistry somewhere that I will look up, and you may have it if you care for it."

The book was entitled "Conversations of Chemistry," or something like it. I not only devoured this book from cover to cover but a neighbor's lad of about my own age took it up with me. He lived about a quarter of a mile away, and we two each had a "laboratory" off in a shed or some basement, and the experiments we performed with our rude home-made apparatus were surprising.

This neighbor's boy was named Corwin Purdy; and when Corwin had made some "great discovery" he would run as fast as his legs would carry him after me, and we two would go back again in breathless haste. I had been trying to make a voltaic pile of copper, zinc, and moistened cloth, using the old-fashioned copper cents. But my voltaic pile did not "materialize" very much. But Corwin found an old copper teakettle, ripped it open, and hammered the sheets out flat. Then he cut them up into pieces about two inches square or more, and made his pile of copper, zinc, and cloth. These squares of woolen cloth were soaked in slightly acidulated water; and when he succeeded in getting a real electric shock he ran for me so much out of breath that he could scarcely talk.

Our craze for chemistry soon brought us in contact with the village doctors, and they loaned us a helping hand. I remember distinctly Dr. Ferguson and Dr. Parleyman. The Rev. Mr. Hughes, the minister, also encouraged us, and placed his whole extensive library at our disposal. The village miller took the *Scientific American*; and when the boy of only nine years of age wanted to "borrow" his back numbers he demurred a little. Finally he said, "Why, my young friend, if you are really going to be a reading man, I have a whole year's back numbers of the *Scientific American* bound up after a fashion, and I will loan them to you."

I have been in close touch more or less with the *Scientific American* now for more than 60 years; and I can tell you it has been worth to me a great deal by way of posting me in regard to true science and better methods of sifting the wheat from the chaff.

But chemistry and electricity were not my only craze. I seem to have been a natural explorer. I watched the hens and chickens as well as nature's display whenever there was a thunderstorm.

Let me digress a little right here. My love for books, and my extensive reading, enabled me to read, write, and spell, without giving very much thought or care to either unless it was the writing. In those old days we learned spelling in a long class, the best speller going up to the head. Well, while the other pupils were poring over their spelling-books I had no spelling-book at all. I did not need any. It seemed to be a natural gift for me to be able to spell. I not only loved books but I loved the queer crooked spelling that fixed itself in my mind without any effort. Of course, we all know about the cranks on spelling, and sometimes they can "spell" without being able to do much else. Well, on the last day of the school I was at the head as a matter of course. The trustees or directors were on hand on examination day; and after hearing me spell, one of those dignitaries made a remark something like this, pointing his finger at me:

"There's a boy who studies his spelling-book."

At this sally there was a queer smile, not only on the faces of the pupils in the class but on the teacher's face also; and I do not know but there was almost a titter among all the children. It was because they all knew that I had no spelling-book and had never looked into one during the term. Well, notwithstanding the above, I was awarded the prize—a "two-shilling piece." Nowadays it would be called a "quarter."

After school was out I told my good mother I wanted to invest my prize money in something that would grow, and finally we decided on a couple of laying hens. In those days they were only a "shilling apiece." Now, my good grandmother, who lived two miles and a half south of Mogadore,

in a big brick house, had some yellow hens which she greatly prized. Two of them had a habit of getting into the cellar kitchen and laying their eggs in the old brick oven. Of course they had to lay them outside when baking day came around. Well, I walked two miles and a half down to grandfather's, and found nobody but him at home. He sat in his chair in this old "cellar kitchen." Now, grandfather Hart and I were good friends because he was at work on a perpetual-motion machine, and I was greatly taken up with "seeing the wheels go round." I was so full of my particular enterprise that I walked up to grandpa and showed my spelling prize. I think there was a hole through it, and a red or blue ribbon was tied to the coin. I told him I wanted to swap my prize money for two laying hens. The two hens were standing in that brick-floored kitchen at the very time we were talking. He approved of my speculation, and told me if I wanted hens that would be sure to lay I had better take those two cream-colored "biddies." They were so tame I had no difficulty in getting one under each arm, and then off I started on my trip of two and a half miles. But by the time I displayed my two treasures to my good mother I was pretty tired and dusty, for the hens became heavier and heavier as I hurried along, barefooted and barelegged.*

Did the hens lay after being transferred to a new home? To be sure, they did. All the hens I have ever kept always laid. When I got down to my Florida home a year ago my flock of 50 or 60 laid only about half a dozen eggs a day; but they commenced laying, one after another (as soon as I got around), right along, until I had upward of 40 eggs from 60 hens. It was because I loved them and made friends of them.

Well, just here I am ready to introduce another friend who lent me a helping hand. He was the village schoolmaster; and let me say right here that, after my two hens got to laying nicely, a neighboring woman said she had a Black Poland hen with a brood of chicks, and they were making such a mess with her garden and flowerbed that she would sell me "the whole shooting-match" for another "two shillings." By this time I had sold eggs enough to be able to purchase the hen and brood; and, oh what a delight and joy was that mother-hen with her brood of white top-knotted Polands! From that day to this the sight of a real top-knot Poland makes my heart bound.

Well, the schoolmaster suggested I should "keep books" to see whether my poultry paid expenses instead of "eating their heads off," and hence he suggested that the latest up-to-date manner of keep-

* My! but did not grandma make a fuss when she found her two favorite biddies were gone? She said Amos must bring those two hens right straight back; but when she came to Mogadore and found what a nice house and yard I had for them she changed her mind, especially when she considered it was her favorite grandchild who had appropriated the two cream-colored hens.

Even at that early age I had caught on to the secret of making the hens lay in winter; and one time in January when there were no eggs in the market, a rich man by the name of Moore sent word that he would give me 25 cents for a dozen eggs. I think the regular market price was 8 or 10 cents in those days. Well, I hurried off, full of animation and delight, with my eggs. But I did not cover them up properly, even though it was zero weather; and when I reached his home two or three of the eggs had frozen and cracked open. I thought, of course, I would not get my 25 cents, and began to cry—perhaps partly on account of the cold; but he said, "Do not cry, bub, here is your money. The eggs will be exactly as good for us, for we will keep them frozen until we want to use them." Then I wiped away the tears and rushed back home to give the hens credit, in my double-entry book-keeping.

ing accounts was double entry. By the way, this good friend also taught me penmanship, and during the winter, when eggs got up to a big price, my double-entry book-keeping was all over on one side of the ledger. It was all profit and no loss.

I might mention, as a sort of side issue, that I had an older sister who was not only bright but fairly good-looking. In fact, she taught school when she was only 15 years old, and a country school at that. Well, one day the schoolmaster, in talking to me about my chemical experiments, said he thought he would come over after school and see my "apparatus." I remember I was a good deal disappointed. I told my mother that I did not believe the schoolmaster cared very much about chemistry after all. He did not seem to notice any thing very much except that older sister I have been speaking of. After a while they were married, and, of course, all the family were expected to be present at the ceremony in the evening. But that night there was to be an "electricity show" at the Methodist church. I had already become acquainted with the professor; and the idea of my missing the show simply on account of so trifling an event (!) as the marriage of my sister was preposterous. I had always been a very obedient child; but I then and there decided "things had reached their limit." There was really a prospect of a thunderstorm right there, besides the one over at the church, unless I could be let loose at "early candle-lighting;" and so the marriage was performed before the candles were lighted instead of after.

Now, all the above looks as though I was a model boy, does it not? and I know of one little woman who may make a fuss if I do all this bragging of what a precocious youngster I was, instead of telling a little something on the other side; so, before closing let me show you that I was not much different from other "kids" of 10 years, after all. The good miller who loaned me those old copies of the *Scientific American* gave me the sweepings of the mill to feed my chickens to pay for sweeping up the mill. Well, there was sometimes a little wheat scattered on the floor; and notwithstanding all his kindness to me I was not always very conscientious about letting some good grain get mixed in with the mill dust.

Once more, the good preacher who gave me access to his library had a couple of hives of bees, and these hives had "glass drawers" on top. Some wicked boys went in after dark and pulled out one of those drawers; and as I passed by they told me what they had done, and asked me to "have some honey." Even if I was not a "thief" I was at least a "partaker," to a small extent. I am glad to tell you that my conscience troubled me about it, but not enough so as to cause me to go to the good man and confess.

Once more, the good doctor who was such a good friend of mine had a fine tree of Red Astrakhan apples near the fence. With some other boys I went there after dark and helped to pilfer his apples when he had only that one tree. It is true at this very time I was attending Sunday-school regularly, and learning "verses;" but somehow they did not seem to take hold of me at that age in a way that one of older years might suppose they ought to have done. A. I. Root.

NATIONAL "RACE SUICIDE."

And God said unto them, Be fruitful and multiply, and replenish the earth and subdue it.—GEN. 2:28.

What is the use of being patriotic, what is the use of being progressive, what is the use of fighting for one's country and nation, if there are to be no children to take

our places when we are dead and gone? The above was suggested by the following brief note from my long-time friend W. P. Root:

Mr. Root:—I enclose a clipping that is too important to lose. The closing up of it is especially interesting. We are often told that in France, where light wines are used, intemperance is practically unknown; and yet here we see it threatens to exterminate the nation. Experience teaches a dear school, etc. It is worth reprinting. I found it in the *Leader* last night, Nov. 24.

Below is the clipping. Read it and ponder. Is there any moral to it for our own United States of America?

FRANCE HELD MENACED BY DECREASE IN BIRTHS.
RECORD SHOWS 742,114 BABIES IN 1911—100,000 LESS THAN IN 1901, AND EXCEEDED BY DEATHS; LEGISLATION SOUGHT TO BALK DEPOPULATION.

PARIS, November 23.—The birth rate of France was lower by more than 100,000 in 1911 than in 1901. Louis Klotz, minister of finance, announcing this fact to the commission on depopulation at its first session to-day, said:

"Military inferiority, economic inferiority, and the diminution of the power of France in the world, will sooner or later be the inevitable consequences of the sterility of our nation."

The number of births last year, according to M. Klotz, was only 742,114 in the whole of France, against 857,274 a decade ago. In 1907 and 1911, he said, the deaths actually exceeded the births. This was, he continued, a sad state of things, and a great danger to the country, placing France in a situation of inferiority in comparison with the other great nations. The lower birth rate, while a perplexing phenomenon among all civilized peoples, was, the minister said, a greater problem in France than elsewhere.

The births exceeded the deaths in 1910 in Germany by 879,113; in Austria-Hungary by 573,520; in Great Britain by 413,779; and in Italy by 461,771; but in France by only 71,418.

In the course of further remarks, M. Klotz reviewed the ineffective government and private measures taken in the past to help parents of large families to limit the hours of work of women about to become mothers, and to reduce infant mortality. It was necessary, he said, to study these and other factors, including the evil effects of alcohol. The relation of drunkenness to infant mortality would, he declared, in future be studied in every part of France.

High-pressure Gardening

DASHEEN UP TO DATE.

At this date, March 24, some of my dasheens, planted about January 1, are nearly two feet high, with leaves a foot long and eight inches wide; and I find the plants are much the largest at the lower end of the row where the ground is a dark mucky sand, and quite moist, although the plants are almost over a tile drain. I am sure our readers will be interested in the two following letters, especially the first, from the Department of Agriculture.

U. S. DEPARTMENT OF AGRICULTURE
BUREAU OF PLANT INDUSTRY.
Foreign Seed and Plant Introduction.

Washington, D. C., March 19, 1913.

Mr. A. I. Root:—Your letter of March 1 was received some days ago, and we are glad to note that you are so well pleased with the dasheen. I thank you very much for the proof sheets of GLEANINGS, in which your article concerning the dasheen appeared. I was personally much interested in the part of the article that preceded the one on the dasheen.

In accordance with your desire we have arranged to send you from our station at Brooksville, Florida, seven pounds of dasheens under our number 15395. A sheet of cultural directions is herewith enclosed.

Very truly yours,
R. A. YOUNG, Scientific Assistant.

Mr. A. I. Root:—In response to your recent communication regarding dasheens I will say that our company has a quantity of dasheens for planting this season; but we have not figured on selling very many, as they are in demand here. Last fall we built a warehouse for them, and have been keeping them stored, and they are now in good shape. It would require about five bushels to plant one-fourth acre. We could spare you five bushels at \$2.00 per

bushel, f. o. b. Brooksville, for seed. Less quantities, \$2.50 per bushel.

BROOKSVILLE DEVELOPMENT CO.

Brooksville, Fla., March 19.

I was agreeably surprised to find the price already as low as \$2.00 per bushel. As Irish potatoes are almost if not quite that at retail here now, it is no wonder that many families at Brooksville are using dasheen in place of potatoes. Our good friend Irving Keck, who has just paid us a visit, says Dr. Kellogg, of Battle Creek Sanitarium, has just bought a carload at Brooksville, for their invalids and guests. Now, with all this great excitement going on, how is it possible no great seedsmen as yet advertise dasheen?

U. S. DEPARTMENT OF AGRICULTURE
BUREAU OF PLANT INDUSTRY.
Office of Foreign Seed and Plant Introduction.
CULTURE OF THE DASHEEN.

The dasheen requires rich sandy soil, very moist, but well drained. The plants will not be greatly injured by occasional flooding of the land for a short period. Such lands as the so-called hammock lands of Florida are especially adapted for the cultivation of this crop. Any low-lying, sandy lands fairly well drained, but still too wet for general field crops, can be used to advantage. On these low lands it would be advisable to plant on ridges.

For best results a liberal amount of well-rotted stable manure should be mixed with the soil. Where the soil is very sandy, it is well to add a fertilizer rich in potash. Planting should be done as early in the spring as conditions of soil and climate will permit. This may be as early as the first of February in south Florida, and as late as the middle of March or the first of April in the Carolinas.

For field culture the tubers are planted, singly

and entire, from two to three inches deep in hills at a distance of three feet, in rows four feet apart. This will permit horse cultivation. During the summer, in cultivation the soil should be gradually drawn to the plants and the plants kept free from weeds. They usually require little cultivation after becoming large enough to shade the ground. Well-grown plants will reach a height of $4\frac{1}{2}$ to 6 feet or more in midsummer.

The crop matures in about seven months, although the tubers can be utilized for home use in six months or less from planting. Harvesting of the main crop may be deferred a month or two if desired; but if it is to be done at one time, in order to have warm dry weather for the dasheens to dry properly on the ground it should not be delayed till danger of frost. Maturity of the crop is usually indicated by a partial dying-back of the plants some time in October. It will sometimes prove advantageous, in practically frost-free localities, or where the roots can be protected, to leave them in the ground until wanted for use or until spring.

A ten-inch plow has proved satisfactory for turning up the plants when the area grown is large enough to justify its use. The plants are then grasped by the tops, and the clumps thoroughly shaken to dislodge as much of the soil as possible. They can then be broken apart by means of the tops, and, in dry weather, the tubers, with tops still attached, be left on the ground to dry for 4 to 6 days. The tubers should not in any case be exposed to frost.

Dasheens should be stored in a dry place of moderate temperature where the air can circulate freely among them, or they may be placed in dry sand or earth.

Wesley and I are now as busy as bees getting that quarter-acre ready for the tubers; and to make room we had to dig the wonderful Red Triumph potatoes I told you about. They didn't go all to vines, as Mrs. Root feared—not much. We ate and gave the neighbors quite a few, and have just sold three bushels of great beauties at \$1.50 per bushel. Poultry manure did it mostly, assisted by a damp soil that holds moisture, even right over the tile drain; and, thanks to a kind Providence, no frost but plenty of rain.

MY POTATO STORY.

A year ago, or perhaps a little more, you remember that I had a good deal to say about growing potatoes in the back yard. I said you could not only keep chickens in the back yard so as to help out quite considerably, but you could also grow potatoes; but, of course, I didn't mean that you could grow potatoes and chickens in the same yard. When I got home to Medina last spring I undertook to "practice" what I had been "preaching;" but although my ground was well underdrained, the exceeding wetness of last summer hindered largely. Another thing, I couldn't get any early potatoes to plant. After exhausting attempts in our neighborhood I sent to one of the leading seedsmen in Cleveland and told him to get me some extra-early potatoes—

Early Ohio or Bliss Triumph—if possible. The only answer they gave was to get me a bushel of *Early Rose*, and these had to be shipped by express from away up in Michigan. Just think of it, will you?—sending to Michigan for potatoes, and paying \$2.00 a bushel and express charges, and then being unable to get any thing better than *Early Rose*! Although the *Early Rose* was not much of a success we decided to bring some of them along with us when we came down to our Florida home, about the first of November. While potatoes were then 40 cents a bushel in Ohio they were 40 cents a peck here in Florida.

The potatoes here in Florida offered for sale in the groceries were not only 40 cents a peck, but they were of a very poor quality at that. In fact, Mrs. Root had sometimes to pare off and throw away almost one-half of the peck of potatoes for table use that cost us 40 cents.

Now, with this condition of affairs I declared I would plant some potatoes just as soon as I could get a piece of ground ready in the garden; but then the same question came up again, "Where can I get seed that will grow?" Potatoes brought down from the North, and planted here in Florida in November or December, of course, would not grow at all. As we had this same condition of affairs a year ago I decided that I would come out ahead this year any way. Before I left here last April we dug two or three bushels of nice Triumph potatoes and packed them in dry sand in our incubator cellar, having been told they would keep nicely this way, and be sprouted all ready to plant when I got back in the fall. It would have turned out all right had not the rats discovered the potatoes; and when we got back here there was only a great pile of worthless skins. The rats had eaten them all. I ought to have had sense enough to surround my potatoes buried in dry sand with inch-mesh poultry netting; but we shall only have to live and learn a little. It was along in December before I was enabled to get any potatoes suitable for planting at once in Florida. I scanned the papers and catalogs; but along toward the middle of December my good friend down at the dock, Mr. S. C. Corwin, advertised Triumph potatoes ready to plant. I went down at once and got about a bushel. The price, of course, was pretty well up—\$2.00 a bushel. They had just begun to show sprouts, and were just right to plant. I was so much in a hurry to get my potatoes to growing that I planted half a dozen hills after dark.

Now, before I proceed to tell you what

happened to those half-dozen hills, I want you to listen carefully to the following:

Some two or three years ago I became so well aware of the need of underdrainage here in Florida that I spent about \$25.00 in hard-burned tile (I think brought from away up in Georgia) to underdrain a part of my garden. Well, when I got here in November I found a tremendous growth of grass and weeds all over this garden spot where I had laid the tiles. I said to Wesley, "Wesley, I don't suppose it is possible for you to spade under all this trash."

He replied, "Oh! yes, sir. I can spade it all under nice and clean if you want to have it go in."

I said, "Go ahead."

Well, I planted these half-dozen hills of potatoes right where he turned under all that grass. It had been spaded perhaps three or four weeks, and we had plenty of rain, so it was well under the work of decay. You remember what I said about planting whole potatoes to get some extra early. Well, in order to *practice* what I have been preaching I selected half a dozen great big nice Bliss Triumph potatoes, with sprouts just showing as I told you, and planted them right over the underdrain, and right in the midst of this nice decaying grass and trash. In a few days they were up, and, oh how they did grow! I called in my friends and neighbors, and the visitors that came from the far North, and showed them my potato-patch. The vines were not only fine and luxuriant, but the leaves were so much larger than anybody ever saw potato leaves before, that people hardly knew they *were* potatoes. As I told you before, no sort of potato-bug or flea-beetle marred the beautiful nice green foliage. My neighbor Rood, who does every thing on "high-pressure" principle, said that *he* had never seen any better potatoes than mine. After they had been planted about five weeks, another neighbor (and also another bee-keeper) came and took a look at them, and he said, "Why, Mr. Root, there are potatoes down under those vines already." I told him I guessed not—that it wasn't quite time for potatoes; and, besides, no blossoms had showed themselves yet. But he stooped over and pulled back the dirt, and showed me potatoes as big as hens' eggs. When they had been planted six weeks we had potatoes as big as anybody would care for for table use. I haven't dug any whole hills yet, but I tell you there is going to be a tremendous yield. Mrs. Root kept cautioning me all the time that they were going to be all *vines* and no potatoes; but I tell you the ground is popping up on all sides, and

there is no mistake about the potatoes as well as the vines. I want to emphasize again the importance of turning under decaying hay, leaves, or trash of that kind. This gives the potatoes a chance to develop in their natural beautiful shape without being crowded and squeezed by hard unyielding soil.

Well, after planting the few potatoes we proceeded to fix the ground and put in more every few days. At first I began to fear that the immense growth and yield were owing to the fact that we had picked on a particular spot where there seemed to be partial—I might almost say natural—irrigation. But since then I have been trying these same Bliss Triumph potatoes at different points all over our five acres, and by the alligator cave I have some that begin to look now almost as promising as those up here near the house. You may inquire in regard to the fertilizer. Well, we put on only a very little fertilizer; but the spot where these immense potatoes are growing was where the poultry had been in the habit of scratching and digging and dusting for perhaps several summers past. This has probably much to do with it. Of course, other people are *now* putting new potatoes on the market, heaped up before the windows in our groceries; but the price, instead of being 40 cents a peck, is now 50 cents a peck, because they are new potatoes, the first put on the market.

Now a word to those who are writing me almost daily to know whether they can come down to Florida and make a living growing celery, grapefruit, oranges, etc. I think it is very unlikely that one brought up in the North can come down here and make it pay growing southern crops—at least not until he has had practice here and learned by experience; but I do think there are thousands of people who could come down here to Florida and make a good living growing *potatoes* if they will only take the pains to *do things right*, and take advantage of modern methods and discoveries. Let me go over them briefly.

You will first have to purchase tiles and get your ground thoroughly underdrained. The cement tiles that are used largely in many places don't seem to answer here. There is something in our Florida soil that rots or disintegrates them. I have lost quite a little money, and my neighbor Rood a good deal more, in investing in cement tiles. Secondly, you must have humus to grow potatoes here in this Florida sand. Thousands of people are burning up the trash in order to clear off their ground; but according to the Florida Experiment

Station it would be worth *nine times* as much if turned under and rotted the way I described in growing my potatoes. Again, you must have good seed, and you must give it good care. If you can grow potatoes successfully in your back yard or garden up north I think you ought to be able to grow them successfully here in Florida. I suppose you are well aware that hundreds of carloads of potatoes and other things are shipped daily from Florida up into the North. Just a little more about good seed.

When friend Corwin put his notice in the paper about "seed potatoes ready to plant" he also stated that this seed had been grown expressly for him for this *particular* season of the year. In order to have potatoes ready to plant, say in November, December, and even in January, they must be grown somewhere at a season of the year so they will begin to sprout and be ready to grow about the time when they are to be planted. There are certain seedsmen in the South who make it a part of their business to be able to supply potatoes ready to plant in the months I have mentioned. You must have the right kind of seed. If you don't you will fail. So far as I know there is nothing better in sight at the present time than the Red Triumph that I have spoken of. It is a most handsome potato; and when they are thoroughly ripe it is about equal in quality to any early potato we have. The Early Ohio might do as well down here, although I have never been able to try it. Let me mention right here that some years ago I happened to be present at a farmers' institute in a rural district, and a discussion was going around in regard to growing potatoes; and the farmers there in Ohio thought if they could be sure of 40 cents a bushel they were having a pretty good thing in potato-growing. As I had published a book on potatoes (or, at least, my good friend Terry and myself had put out the book), somebody inquired for A. I. Root. As I rose to speak I told the good people that I was afraid I wasn't enough of a farmer to be able to grow potatoes, and make it pay at 40 cents a bushel. "But," added I, "if you will give me 40 cents a *peck* I think I could get along right smart." This statement awakened quite a little uproar.

Dear friends, almost every one of you whose eyes rest on these pages, no matter where you live, can get 40 cents a peck for your potatoes if you set about it right now to get ready. Spread your seed potatoes out in the sun, at least a few of them, as many as you may want, in some place where they won't freeze, and induce them to put

out short stubby sprouts as quickly as possible. Then I think it would pay you to have a few cold-frame sash. Along the last of this month you can put the potatoes out pretty close together under glass; and along in March, in many localities, you can get them out under good rich ground prepared as I have outlined in this potato story, and have them ready to grow whenever the weather will permit. Should there come a frost it is an easy matter to give at least a few potatoes a little protection. The grain-sacks that are a drug here in Florida answer every purpose nicely. Rip up the seams and spread the bags over the potatoes just coming through the ground, and they will ward off considerable frost. When your potatoes are ready for market they will be quite a little ahead of those shipped from away down here in Florida, or Bermuda, or other lands.

About the nicest way to cook new potatoes, especially those that are only partially matured, is to boil them with green peas. That is just what we are having for dinner almost every day just now. Don't undertake to dig the *whole hill* of potatoes when they get so as to be fit for table use. Push your hand down through the hill in that rotted straw and hay that I mentioned, and pull out the potatoes as you happen to need them, and let the vines grow right on. Potatoes planted very early are very unlikely to be troubled with potato-bugs or flea-beetles, or any thing of that kind. Teach the children the trick of growing stuff under glass and they will soon not only be a great help, but it will be an excellent part of their education. As I write this the "corn-growing" boys are being discussed, especially in regard to their trip to Washington, as provided by the different States; and Florida is just now discussing the matter of offering her boys not only a premium but a trip to Washington also, for growing fields of corn that beat any thing their "daddies" ever saw or heard of. Now, let us all offer an inducement to get the boys to growing potatoes; and why not let the girls share in this industrial education as well? This has been taken up by agricultural papers, and it will be very strange if we don't find some girls who are just as smart as the boys, even in growing corn, potatoes, and other things.

COLORADO APPLES, ETC., BY PARCEL POST;
SOMETHING FROM OUR OLD FRIEND,

J. A. GREEN

Mr. A. I. Root:—I regret that our personal acquaintance has not been as intimate of late years as it was when I lived in Illinois and gave all my time to beekeeping, so that we occasionally met at

conventions. However, I have read with interest all your writings, and have not forgotten the old times. I am now engaged to a considerable extent in the fruit business, so I have been interested in your "apple talks" within the last several months. I have been packing and shipping apples for several days, and it occurred to me that you might like to see some samples of the apples we grow in Colorado, so I packed and shipped you to-day by parcel post a few apples. You will find the papers in which they are wrapped stamped with the name of the variety. First there is the Arkansas Black. We do not call this a very good eating apple; but its high color makes it sell very well—highest of all our apples this year, and it is also a very good keeper. I have kept them over a year in good condition in our cellar. Then there is the White Winter Pearmain. This, when at its best, is my favorite eating apple, though these are somewhat past their prime.

Then comes the Winesap, which is one of our principal varieties. A collection of Colorado apples would be incomplete without the Jonathan, so I send some of these, also the Grimes Golden, though I had nothing left but culls in either of these varieties. Of course we raise a great number of varieties here,

though there are only a few that are planted any more. Jonathan, Winesap, and Gano are about all that are planted any more, and I do not think many Ganos will be planted hereafter.

I should be glad if you could let me know how the apples stand their long trip. I have been wondering if the parcel post would help us to solve the problem of getting our apples to the consumer, and getting rid of the excessive profits charged by the middlemen.

JAMES A. GREEN.

Grand Junction, Colo., March 10.

The apples came to hand in excellent condition; but the postage was 72 cts. on 15 apples—not a very good showing for parcel post from *Colorado to Florida*. The wooden box (to make them safe) weighed 2 lbs., and the 15 apples 5 lbs. The Arkansas Black is a most beautiful apple, very hard and crisp, but not quite equal in flavor to the justly celebrated Winesap. The Delicious apple I have mentioned in a former article kept perfectly until March.

Poultry Department

THE HEN'S NEST AND NEST EGG.

On page 426 for GLEANINGS for July 1, 1912, I gave you sketches of a hen's nest as I would have it for our convergent poultry-yard. Well, I have just completed a series of six nests after this plan, and I want to tell you something of how they work. Before I had built my nests, the hens had been laying in a pine box in their roosting-house covered with burlap, by means of some barrel-hoops nailed to the sides of the box, and curved over the top. This particular nest suited them so well that six or a dozen hens were laying in it every day. After I put in my new nests with the dark alley for them to go through, with some nests nicely fixed with dried grass and nest eggs, the hens, when they were ready to lay, climbed up the little ladder and looked the nests over and spent quite a little time investigating, but they did not lay any eggs. Finally I noticed in one of the poultry journals that the hens had a great preference for laying where there is a nest full of eggs already, as their natural desire seemed to be to accumulate a nest full before wanting to sit. So I put several nest eggs in the new nest; but they went in, investigated, and spent some time cackling, but did not lay any eggs. Finally one day I took three warm eggs, just laid, from their old nest in the poultry-house, and put them into the new house along with the china nest egg. This seemed to have the desired effect, for they went to work and laid three or four eggs during the day in that same nest.

Now, you will notice I used the expression "china nest egg;" but, if I am correct,

when you go to almost any of the stores now and ask them if they have china nest eggs they reply, "Oh, yes!" and give you some eggs made of white glass. They seem to be getting thinner and smaller, until I should exceedingly wonder if any sensible hen would think of calling that a nest egg. They are also made so light that the hens knock them off the nest; and down here in Florida the skunks and opossums, when they come around at night to see if any choice eggs have been left in the nest, have the habit of biting them and crushing them to pieces. In fact, one moonlight night I caught a skunk snapping an egg around the poultry-yard and trying to bite it. When it would bounce and fly off he would try again. He seemed very much disgusted to find an egg so smooth and slippery that he could not crush it and get the richness inside. I have in vain asked keepers of poultry supplies for some better substitute. Of course we have such eggs advertised, and I bought quite a number of them; but they do not seem to be much better than the glass egg. They are heavier, and stay in the nest better; but when skunks or other vermin get hold of them they are easily crushed. I have an impression that some of the hens, discovering they are made of chalk or lime, or something of that sort, have been pecking them to pieces themselves in order to get material to make eggs, especially if they do not happen to be well supplied with lime or oyster-shells.

I do not like the wooden eggs (such as The A. I. Root Company used to sell years ago), because they are so hard to keep

clean. The paint or varnish, or whatever is used, very soon gets soiled, and the eggs get to be unsightly, and, very likely, unsanitary. There used to be years ago a genuine porcelain egg that was just about as heavy as a hen's egg, and was proof against all these troubles that I have mentioned. Can anybody tell me where I can get an egg that is porcelain—really porcelain in something besides name? Now, my new hens' nests, which I have taken so much pains with, have proved all right except in one respect. When there is a very hot day, for instance, the hot sun shining right direct almost at right angles on this lid that is to be raised up, makes it, I suppose, almost unbearable inside, because on such days I notice the hens going back to their old nests, and all piled into one nest, or else they stand and wait for their comrades to get through and give them their turn. Of course, I might have trees to shade my hens' nests; but it would be a little difficult to have shade-trees so the sun would not strike right squarely against some of the nests at a certain time of the day. And I am convinced that, a good many times, the hens desert their nests and go over to the bushes to lay just because the nests are too hot in the middle of the day in this southern clime. It is certainly one very great drawback to have the hens go off in the bushes, under the palmettos, or among this luxuriant foliage here in our semi-tropical land, and steal their nests. Eggs from stolen nests are not fresh, and seldom fit for market. Our government has been passing some strenuous laws in regard to taking eggs to market that were not healthful or suitable for the market. All such eggs can be used at home; but when too many of the hens get to going out among the bushes it gets to be a serious matter. Some poultrymen, I know, take the ground that there is no need of nest eggs of any sort; but they certainly have a very great influence in getting the hens to lay *where* you want them to instead of in some out-of-the-way place where the eggs may never be found at all. Where hens are confined, and do not have unlimited range, it isn't so very important to have nest eggs. But I want my hens to enjoy themselves and be happy, and I want them also to lay where I "elect."

Since the above was written neighbor Abbot suggests that my "convergent nest-box" needs more ventilation. In my efforts to give the biddies *privacy* I forgot *fresh air*. On cloudy days, or in cool weather, the nests are all right; but during sunny days I am leaving the lids propped up a couple of inches.

ROOFLESS POULTRY-HOUSES IN FLORIDA, ETC.

Mr. Root:—In the Poultry Department of GLEANINGS for Jan. 1, F. M. Baldwin strongly advocates roofless coops for poultry in Florida. I would advise new-comers intending to keep chickens not to follow such advice too blindly. Use common sense. Mr. B. claims that poultry are not bothered with vermin in roofless coops. May be not, but there are other ways of getting rid of vermin than drenching the fowls with rain water two or three times a week. When we had dirt floors in our coops, chiggers were a terrible pest. We put in board floors, and have not seen a chigger in years. A roofless coop would be a standing invitation to all the varmints in the neighborhood to come and help themselves. All the coons, possums, foxes, and wildcats in that vicinity would camp around that coop till the last hen was gone. Wire poultry fencing does not always keep them out.

F. H. CHESEBRO.

Boca Raton, Fla., Jan. 21.

My good friend, either you have not been long with us or you have read GLEANINGS carelessly. The term "roofless" does not mean there is nothing overhead to keep out "varmints." On the contrary, I think most of the roosting-places are covered with poultry-netting. The first two years we were in our present Florida home our poultry roosted in the trees, and had no houses at all; and my yield of eggs was as good as with houses. The reason why I changed was the difficulty of getting the fowls, when wanted, and some trouble on moonlight nights from owls. We have had no insects of any kind in our roosting-places since we commenced sweeping up the drippings every morning.

CONVERGENT POULTRY-RUNS ACROSS THE WATER, AND SOME OTHER THINGS.

Dear Sir:—I wrote you, Sept. 9, about the convergent poultry-runs, and you published it on Nov. 15, since when I have not seen any thing further on the matter; so I thought you would like to hear the opinion held over on this side.

The chief drawback seems to be in the great length of the run when compared with the width, as the fowls are not inclined to keep the grass down at any distance from the house; and to overcome this Mr. Wright gives a plan of eight houses, sheds, and runs.

Personally I prefer the colony system, which Mr. Wright credits to Mr. Stoddard.

I am afraid you missed the point in the leaflet taken from the Mark Lane *Express* about lime. Although it was printed in 1910 it was an article on farming in the 16th century in England, and went to show that the old timers knew that lime was good for clovers. Lime and salt are the two oldest artificial manures in existence, and are largely used in this country as well as seaweed.

I was much pleased to see in the Jan. 15th issue J. E. Crane's remarks about the good old blacks. All the other "Gleaners" seem to think them of little value; but I can assure you that I have had Italians direct from Italy and that they can't gather honey as do the blacks, and they are not half as good at wintering.

Editorial

THE COMB-HONEY CANARD, AGAIN.

A SYNDICATED article that is appearing in a large portion of the daily press of the country, written by Miss Ida M. Tarbell, on the subject of glucose, and telling how it has been used as an adulterant, makes this statement:

"They even manufacture honeycomb and fill it with corn syrup."

We wish every one of our subscribers would send in their immediate protest to all papers publishing this, asking such papers to send such protest to Miss Tarbell. We believe she is a candid writer, and desires to tell the truth; but in this case she has made a big blunder. She has implied, also, that the strained honey on the market to-day is nothing but corn syrup, in spite of the fact that the national government, as well as most of our States, has stopped the sale of glucose as honey. Make it plain that there is no such thing as manufactured comb honey, and little or no adulterated liquid honey. Of course we are voicing our own protest direct.

ANOTHER TREATISE ON BEE CULTURE, FROM THE STATE ENTOMOLOGIST OF INDIANA.

THERE lies on our desk a copy of the Fifth Annual Report of the State Entomologist of Indiana. That State has been fortunate in having two entomologists, Mr. Benjamin W. Douglas and now Mr. C. H. Baldwin, both of whom have prepared comprehensive reports on the injurious and useful insects of their State. At the close of the last report appears a brief treatise on bees by D. W. Erbaugh and B. F. Kindig, State foul-brood inspectors. There also appears from the same office a circular of information for beekeepers on the brood diseases of bees, by the Hon. Mason J. Niblack. Mr. N. is an ardent beekeeper—one who has done, perhaps, more than any other man to advance the cause of apiculture in his State. The excellent foul-brood law that has been in force for several years was largely due to his untiring efforts and influence in both Houses of the General Assembly. Indiana beekeepers will no doubt

be able to obtain a copy of either by applying to the State Entomologist, C. H. Baldwin, Indianapolis.

OUR COVER PICTURE.

THE picture on our cover for this issue is one sent us by Mrs. S. E. Howard, of Wakefield, Mass., whose article adorned the pages of our Women's Number, the March 1st issue. Mrs. Howard is an expert, who, having made a success with beekeeping, has been furnishing a number of the popular magazines with illustrated articles showing how and why she succeeds. These articles are refreshing in that they are written by one who is familiar with nearly every phase of beekeeping. A very large proportion of the literature in the popular press in regard to bees is unorthodox in some respects. By this we mean that it is likely to contain some reference or some statement which causes an experienced beekeeper to smile. Mrs. Howard's articles do not contain extravagant claims of enormous profits, nor are they such as to cause any inexperienced person not fitted for beekeeping to plunge wildly into the business without giving a thought to any thing aside from the spending of a lot of time and money.

The view shows the hiving of a swarm. The cluster of bees has just been shaken on to the sheet before the entrance of the new hive, and the bees have begun marching in. This is a sight that never fails to excite admiration or wonder on the part of the onlooker, as the bees when they once start go trooping in, for all the world like a flock of sheep.

THE WESTERN HONEYBEE.

VOL. I. No. 1 of the new bee-journal has come to hand. It announces on the front page that it "is not a competitor nor a money-maker," but is designed to "fill a long-felt want." It is published by the California State Beekeepers' Association, from news furnished by the beemen. At present it is edited by G. L. Emerson, a beekeeper owning and taking care of from

1200 to 1600 colonies. There is a distinctly Western and a professional flavor in the new publication, and the first issue gives evidence that it will indeed fill a "long-felt want." The articles are by a number of prominent beekeepers—men well known through the bee-journals; and, besides, there are contributors who count their colonies by the thousand.

We are glad that its promoters feel that it is not a "competitor." This is a broad, broad world, and a big, big country. California is a great deal larger than some countries, and the second largest State in the Union. We see no reason why the beekeepers of that State should not be able to maintain a journal that will be a credit to them as well as a help. It will build up the industry, and so far from being a competitor it will be an aid to all bee journals.

It will be of immense worth in securing a foul-brood law that will mean something in California. There is much more it can and will do for not only the Association but for the general advancement of bee-keeping within the State and out of it. GLEANINGS is glad to welcome it.

THE BEHAVIOR OF THE HONEYBEE IN POLLEN COLLECTING.

IN our issue for March 1, page 139, we gave a brief review of a bulletin from the Bureau of Entomology, No. 161, by Dr. D. B. Casteel, on the subject of the manipulation of the wax scales of the honeybee. This time we have the pleasure of referring to another bulletin by the same author, entitled "The Behavior of the Honeybee in Pollen Collecting." This, like the other, is extremely interesting, because it opens up a field hitherto unexplored by any one except F. L. Sladen, now Assistant Entomologist at Ottawa, Canada. Much has been written on the value of the honeybee in pollinating fruit-blossoms, clovers, and buckwheat; but the intricate process by which the bee prepares this pollen and deposits it in its pollen-basket, if we are correct, has not been accurately described until Sladen and Casteel gave it to the public.

The matter of *how* the bee takes its pollen from the blossom and stores it in its pollen-baskets, from a scientific point of view, at least is exceedingly interesting; and it has its practical side because it helps to prove that bees perform an almost indispensable service in pollinating blossoms. If any one has ever doubted this proposition he could doubt no longer after seeing how elaborate and perfect are the appliances, the working tools, so to speak, in pos-

session of our common honeybees as well as bumblebees, for gathering and storing pollen. That is to say, if the bee is perfectly equipped for doing this work it certainly must do it.

Very few people have had the time and patience to follow the intricate process of the bees in pollen-gathering from start to finish. In our younger days we tried to discover just how the bees did it; but the performance was so rapid that nothing short of an instantaneous photograph could have caught it. In this connection it should be stated that Dr. Casteel had, of course, all the modern appliances that the government could furnish to aid him in this investigation, and he used them. He called in the services of an expert chemist from the Bureau of Chemistry to determine the nature of the liquid that holds the pollen together; he consulted all the works that bore in the least on the subject; but apparently Mr. Sladen was the only man who came anywhere near telling exactly how pollen is put into the pollen-baskets.

The bee's working tools consist of spines and hairs on its legs; of a long hairy tongue, of mandibles, and fuzz, or hair, on the body, and of pollen-baskets which, so far from being a basket—well, it does not look like any thing except a bee's hind leg. The average person, if he will examine it carefully with a microscope, will conclude that the pollen-basket is the most unlikely place in which to store a lump of bee-bread; but it stores it in great big chunks just the same.

The manner in which the bee gathers pollen varies according to the flowers on which it is working. Sometimes the dust is collected on the hairs of the body as well as on all the legs, antennæ, and head. At other times, only the fore legs, where the flowers are very small, in connection with the tongue, seem to be concerned in the process. On the fore legs is a very interesting device called the antennæ-cleaner, which is used for removing pollen from the antennæ. On the middle legs there is a peculiar kind of spur that is used for kicking pollen out of the baskets on arrival at the combs. On the hind legs are pollen-combs, pollen-baskets, a sort of pincers or squeezers, consisting of a pecten, and auricle. These devices all come into play at the proper instant, as we shall see. In some cases the bees fairly wallow in the pollen dust of the large flowers. On taking wing they proceed to clean themselves through the agency of the special tools provided by the legs, consisting of hairs, pollen-combs, antennæ, claws, all of which,

while the bee is flying, may be engaged in the process of directly and indirectly transferring the pollen from some part of the bee's anatomy to the pollen-basket. "Busy as a Bee," for the bee is busy not only while in the flower, but while it is on the wing. It can not afford to waste valuable time merely in flying, so it keeps its legs busy in making pollen gathered on its body and legs) into a bee-bread, or, more exactly, a pollen paste consisting of honey and pollen grains, making little patties of dough.

The process of following the transference of pollen from the mouth parts to the middle legs, and even to the pollen combs of the hind legs, is not so difficult. Most of the authors who have attempted to describe it have been fairly accurate; but authorities have differed widely as to how the pollen was transferred from the pollen combs on the hind legs to the pollen-baskets; and no one seems to have discovered the correct method until Sladen and Casteel, each independently of the other, dug it out.

Those who have studied the anatomy of the bee will remember that, on the hind pair of legs, there seems to be between the joints a big pair of pincers or jaws. These pincers or jaws are opened when the legs are flexed, and closed when they are straightened out. Some have supposed that the function of these was for the purpose of masticating or working wax; others, that they were used for hanging hold of each other while hanging in the swarm. There have been all kinds of guesses, but they have been wild. Sladen and Casteel have proved beyond a question that they are used for the purpose of pressing the mass of loose pollen and honey, and at the same time forcing it up under pressure into the pollen-basket on the outside of the leg. The pollen combs of the hind legs receive the pollen from the middle legs, and from the under side of the body of the bee. The pecten spurs or the upper part of the pincers catch or gather the pollen from the pollen combs on the opposite hind leg. The jaws close, squeezing the mass so that it is forced under pressure to the opposite side of the leg up into the pollen-basket, just about as you would squeeze putty out from between the ends of the fingers. These little masses of pollen, or mouthfuls, so to speak, are gradually forced upward, pushing the general mass higher up in the basket. The process is somewhat similar to the method of putting fuel in one of our house furnaces. The coal is pushed up from the bottom under the fire-pot, shovelful by shovelful, so to speak, until the fire-pot is filled

full. In the same way the bee fills its pollen-basket from beneath; and this filling continues until the lump of pollen is pressed out in all directions, crowding against the hairs or spines of the pollen-basket, and sometimes away past them; and as the mass is wet with honey it sticks to whatever it comes in contact. The old popular belief was that the middle legs, in some way unexplained, put the pollen in the pollen-basket from the outside. While these middle legs do reach back over the pollen mass in the baskets, the purpose of the movement is evidently to determine whether the lump is holding its position.

The whole process as described by Sladen and Casteel is exceedingly interesting; and it is of more value because each worked out the problem without the knowledge of what the other was doing. It is a marvel that either should have discovered the process; but when it is once explained it seems so clear that there is no room for doubt.

There has been some speculation as to what is used by the bees in moistening the pollen. Some have thought that it was saliva; but the majority have held that it was honey. Dr. Casteel has proved that honey is the agent, for chemical analysis shows that, beyond a doubt. Honey that is obtained from the mouth parts is transferred to the fore legs, and sometimes to the middle legs, and by the latter to the hind legs, or pollen-combs, that catch and receive the dry pollen. This is subsequently worked over and transferred to the pair of pincers already mentioned, before its entrance into the pollen-baskets as just explained.

This interesting bulletin can be secured from the Superintendent of Documents, Government Printing-office, calling for circular 121, and inclosing five cents. Do not send stamps, as the Government does not accept them. It would be well to get in your order early, as the edition of Dr. Casteel's former bulletin, No. 161, on "The Manipulation of the Wax Scales of the Honeybee," was entirely exhausted in a short time. We are pleased to note this, because we want the authorities at Washington to know that there is a big demand for any thing on the subject of bees, and the more of this kind of stuff they can give us, the better.

For convenience in sending for these bulletins the Department will send twenty coupons for a dollar, each of which is good for five cents. Buyers of public documents will find the use of these coupons the most convenient and the safest way of remitting the amount of their purchases.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

DESTROYING the capped cells to prevent swarming is advocated, p. 212. But would not that require very close watching? for are we not told that a colony swarms when the first cell is capped?

MR. EDITOR, you say, p. 246, that parcel-post packages of honey can't go *outside* of the mail-sacks. May be they can't, but they *do*. At least the case of honey I sent to Chicago went that way. Matter of "locality," eh?

TIME was, and not a hundred years ago, when a beekeeper's success was measured by the number of swarms that issued. Now there is a niche in the hall of fame awaiting the man who will give us a profitable way to prevent swarming in all cases.

How nice it would be if you could just divide a colony into two, three, or more parts without having most of the bees go back to the old stand! Well, you can do that very thing if you take a colony from the home apiary to an out-apiary. Then you can bring another colony from the out-apiary and divide it up in the home apiary. Of course, if you have no out-apiary you can shut up the bees for about three days, or you can close the entrance with green leaves or grass and let the bees dig their way out. [You are right.—ED.]

J. L. BYER, your head's level in that talk about syrup vs. honey, p. 253; and I venture to say that in five years you'll go still further and say that, even for wintering, syrup does not equal A1 honey. [What do you mean here, doctor? Do you mean that an A1 honey is superior, irrespective of quantity, to sugar syrup? Perhaps you are right, but we would suppose that you will have not only Mr. Byer but the whole fraternity against you. However, we all agree with Mr. Byer that a pound of sugar syrup in the feeder will not last as long as a pound of honey sealed in combs.—ED.]

FOR half a century there is no one thing in beekeeping I have fought more bitterly and persistently than the swarming nuisance. I don't believe any plan is known that will *entirely* prevent all swarming if colonies are kept strong. But you can come so near to it that it will hardly pay to watch for the few swarms that will run away. You can work for extracted honey, and give abundance—not plenty, but *abundance*—of room for the queen, and also for the surplus, giving much ventilation at each story. Or, especially if working for sections, you can exchange the old queen for a young

one at the beginning of the swarming season.

G. W. DEMAREE, a Kentucky beekeeper, some years ago gave a plan for prevention of swarming that is simple, and has proved successful in the hands of many who work for extracted honey. When swarming-time comes, put the queen in the lower story with one frame containing a little brood, and fill up the hive with combs or foundation. Over this put an excluder, and over the excluder a second story with the rest of the brood. Ten days later kill cells in upper story. These upper combs will now become extracting-combs. [The secret of this lies in giving the queen egg-laying room. The principle is correct.—ED.]

WHEN running for extracted honey it helps against swarming to have the stories "stuttered;" the second story shoved forward to make ventilation at the back, the third story shoved backward to make ventilation at front, and so on alternately. Even for comb honey I like ventilation at back between hive and first super. [This plan is all right when working with ordinary Italians or common hybrids—that is, a cross between Italians and black bees. We tried it out very thoroughly last summer with an apiary of Carniolans. While it checked their swarming it did not stop it. In fact, we do not believe there is any device or method known that will stop Carniolans from swarming if they once get started. This one Carniolan apiary gave us more trouble from swarming than all the rest of our apiaries together.—ED.]

I ARISE, reluctantly, to say to beginners who think of increasing by the Alexander plan as given in A B C and X Y Z that I don't believe there's one locality in a hundred where the plan will pan out as there represented. In my locality it would make the increase all right, but it would make a bad dent in my honey crop instead of nearly doubling it. If your bees have a reliable buckwheat harvest of thousands of acres, and you want at least part of your crop extracted, then go ahead. [You are probably correct for your locality; but you will remember that Mr. Alexander places strong emphasis on stimulative feeding. And you will remember that his main honey crop did not come on till about the first of August or later; so, therefore, what might work with him might be a failure with you, where your honey-flow comes on about the first or middle of June, and closes about July 1.—ED.]

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

I read this headline in the issue for April 1: "Painting queens so that they may be quickly found." A little more training of the eye will help to a great extent. I doubt whether the painting idea makes very much headway.

* * *

Mr. R. M. Spencer says, April 1, p. 209, "We use a method of preventing robbing during this early spring work by going over the hives so fast that robbers can not get a chance." I guess that is "going some," all right.

* * *

California showed up well in the April 1st issue. Besides the cover picture, we were represented by several good articles. Those honey-tanks shown on the cover are about as large as are ever used, and not very often do we see more than one at an apiary, even in this land of floods and drouths in the honey-flows.

* * *

Did you ever stop to consider the amount of excitement a swarm of bees will cause? I once saw an entire family, with most of the tin portion of the kitchen utensils going across the fields and meadows in a merry chase after a swarm, but they were not successful in stopping it. A hive once sat in the back yard of a neighbor year after year, and the bees were hardly noticed until they swarmed out; then great excitement was started at once, and all hands were called to hive them quick.

* * *

A CORRECTION.

I am in receipt of a letter from Mr. F. C. Pellett, State Bee Inspector of Iowa, in which he calls my attention to the fact that I have misstated the report of the Iowa State Beekeepers' Association, on which I made comment in the April 1st issue. Mr. Pellett says, "The joke is on you; put on your glasses, and read the report of the Iowa convention again." Well, I read the report, and I humbly beg the pardon of the Iowa beekeepers; but in justice to myself I think Mr. Pellett should have recommended an optician, inasmuch as I have not as yet begun the use of glasses. It is just possible I may be in need of them. Any way, I must admit that I did not observe as closely as I should have done the clause relating to being accompanied by a certificate of health signed by some duly authorized Government or State inspector.

PROSPECTS FOR HONEY.

We are nearing the end of the second week of April with little if any better prospects for a honey crop than at the same date last season. So far we have had a very light season's rainfall, and at this date it seems probable that our rains are over for the season. We may expect some showers during the next four weeks; but any great amount of rain is only possible. The button sage in this locality, no matter how much it may rain, is practically out of consideration for the season. It is badly frozen, as I have before stated. Much of it will not put out a bloom shoot, and some not even a green leaf. The orange-trees are just beginning to bloom, with bees on an average in better condition than last season, so we may reasonably expect some honey from that source; but from the wild flora there is little in prospect. It seems probable that the season will be finished with a total of less than last year's crop, and the price ranging around 8 cts. Good rains would, no doubt, be of some aid, but it seems out of reason to expect any great amount of honey after the past six weeks of practically dry weather.

* * *

FIRST ISSUE OF THE WESTERN HONEYBEE.

The first issue of *The Western Honeybee* is out. I believe it is of sufficient merit to recommend itself to the western beekeeper. Like all work undertaken by the association, it must be supported first and most loyally by association members, who, with their best efforts, can help gain the support of the western beekeepers as well as many in the East, for there are many in the East who will be subscribers for the sake of knowledge. The more bright journals we have, the greater will be our opportunity to profit by the ideas we get one from the other. It is my wish that *The Western Honeybee* may take its place in the front rank of bee journals of the country, and I shall lend an effort in making it a success, though I expect to continue my work in these columns as long as I can feel that I am aiding the beekeepers of my State or elsewhere, or until the editors tell me that my services can be dispensed with. I have been editing this department for nearly two years; and while I do not feel that I should grab in with both hands and take more than my share of credit, I do have a feeling that I have done something to interest the California beekeeper and keep alive an interest in our State affairs.

Beekkeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

Mr. Chadwick says, p. 47, Jan. 15, that Colorado claims 27,000 colonies of bees. I wonder where he got that information. The 1910 census gives Colorado 70,000, and that is very probably below the figure, as bees in towns were not counted. I do not care to guess, but I am of the opinion that, if every hive containing bees were counted, the number would be over 100,000. Mesa County has over 14,000 colonies, according to Mr. Harkleroad, the inspector; and of this number over 11,000 were inspected during 1912.

California is, without doubt, a much heavier honey-producer than Colorado. We are willing to grant that; but we have some of the best beekeepers to be found anywhere, and the homes of our beemen are a credit to the State. I have a collection of photos that attest it, and some of these days I am going to show them. The homes of a nation are its stronghold. The past fall, Mrs. Foster took nearly a thousand-mile trip with me, and she visited in the homes of beekeepers for about a month. She formerly harbored the idea that beemen were mostly eccentric, a little off in the upper story, so to speak. When she reached home she had changed her mind, and expressed herself to the effect that beemen know how to share the conveniences of modern life with their wives, and how to enjoy life. They struck her as being a live, alert class with a business requiring training and mental alertness. So there you have the opinion of a college girl, newspaper woman, etc., who happens now to be Mrs. Foster.

* * *

ALFALFA NOT BEING CUT AS EARLY AS FORMERLY.

While on the Colorado Agricultural College demonstration train I had several very enjoyable visits with Mr. P. K. Blinn, alfalfa specialist for the Colorado Experiment Station at Rocky Ford. There is no man in the United States who knows more about alfalfa than Mr. Blinn. He has experimental plots of many varieties of alfalfa, testing seed production. The nectar production in relation to seed production is one of interest to him, and some tests are contemplated to find out, if possible, whether the heavy seeding alfalfa is also heavy in nectar production. The Grimm alfalfa is in the lead at present, as regards tonnage and hardiness. It is much more profuse in its blooming than any other varieties—all colors of bloom from white, pink, blue, and purple shades. If, as is likely, it is as heavy

a honey-producer as it is a blooming crop it will be a winner for the beeman. And here is another point—it begins blooming before its gets its growth. The farmers will not cut it until after it has bloomed for some time. The seed is from fifty cents to a dollar a pound as yet; but the price will come down when it is produced in greater quantities. Mr. Blinn also brings this good news to the beemen—that there is a change of opinion regarding the cutting of alfalfa before it blooms. Alfalfa is not being cut as early as it was five years ago.

* * *

SEASON PROSPECTS.

Early in March, breeding was going on freely in normal colonies, only the weakest ones being without brood. But March went out like a lion, and considerable brood was chilled. Many colonies will need feeding in northern Colorado before the honey-flow begins. Better lay in a supply of sugar. It is cheaper now, March 26, than it has been for a long time—\$5.00 per hundred, and less for beet sugar.

A snowfall of 19½ inches fell March 25th, nearly half the whole winter's fall. There is an abundance of snow in the mountains, and the bees are in fine order. The only thing we fear is the late frost that blights the alfalfa and destroys the nectar secretion of the first growth, and lessens the secretion of the second and third bloom.

The beekeeper in the exclusive alfalfa districts has troubles altogether different from those of the man in the fruit areas. The alfalfa-district man is annoyed by spring winds that retard early breeding. There is also a very marked lack of early pollen. These conditions obtain in the Arkansas Valley in Eastern Colorado, and the Platte Valley in Northern Colorado. Some beemen move their bees near the river in the valley for the winter and spring, moving back to the alfalfa fields about the time for the bloom on the alfalfa to open.

In the fruit districts bees build up with remarkable rapidity, and swarm and swarm just as they do where they wish for a non-swarming strain of bees. It is easy to keep up one's numbers in the fruit district if you are not wiped out by spraying. Which location will you take? The beemen feel that they are between the devil and the deep sea. Some say that they believe they will move back east and live with wife's folks—take up cellar or clamp wintering, and put up with cold winters, and floods in the spring.

Conversations with Doolittle

At Borodino, New York.

ARE DRONES A NECESSITY IN NATURAL SWARMING?

I am told that drones are necessary when the bees make their plans for natural swarming, for no swarm will ever issue unless there are mature drones or drones in the brood, on the principle that the parent colony would become extinct from the leaving of the mother-queen with no provision made for the mating of the young queens later. This would be especially true with all isolated colonies; and it is calculated that the bees of each colony consider theirs in such a light, no matter how many other colonies any apiarist may mass together. Now, if this is a fact, would it not be an easy matter to do away entirely with natural swarming by excluding all drone comb from all the colonies in any apiary?

The exclusion of drones from colonies for the prevention of swarming is not a new idea. It does seem reasonable at first that no colony would swarm unless there were a reasonable prospect for the perpetuation of the old colony from the young queens, always left behind in the brood form, becoming fertile later. But so far as I know it has never been announced that successful non-swarming has ever been obtained by excluding brood comb. Several have announced, during the past quarter of a century, that drones, being a necessity to the permanence of the colony, a logical deduction would be that their entire absence would delay the preparations for swarming that are usual to all parent colonies. It has been assumed that the rearing of drones is the first preparation which leads to the building of queen-cells, which, when sealed, constitute the completed preparations.

While on this subject it might not be amiss to notice some other vital principles which induce swarming, and which will afford us a more intelligent understanding of it. As long ago as 1852 Mr. Moses Quinby named three causes which induce swarming, and to-day they are recognized as the prime factors. As I look back over the years which have passed since then I can not refrain from referring to the wonderful accuracy of most of Mr. Quinby's investigations. Even the limelight of this twentieth century has cast a shadow on very little if any of the investigations which he gave to the world, and the larger part of such were carried on when a box hive was the known palace of a colony of bees. His three causes or factors are these: "A crowded hive, a large brood, and a good flow of nectar." These are usually sufficient to induce swarming.

Another factor bearing on these is that of temperature, which will hasten or retard the preparation just in proportion to the

heat or cold. What is known as the swarming fever or swarming impulse is a strong factor when the other conditions are combined. These conditions being absent, no amount of drones would cause swarming; and with their presence I have known colonies to swarm without a single drone or even any prospect of any.

This no-drone theory is not new, as I hinted at in the start. At the time it was agitated, fifteen or twenty years ago, in order to test this matter as well as another still more strongly advocated as a fact, that no colony would swarm with any queen of the current season's rearing, I made several colonies as follows: A nucleus was formed by taking the queen away from a weak colony of bees, and confining the bees of this weak colony on two frames of brood and two of honey, the brood being between the two of honey. This nucleus was given a ripe queen-cell. This gave a laying queen in from ten to twelve days, at which time there would be bees enough to care for a hive full of combs, as the larger part of the brood would have emerged if combs of nearly all sealed brood had been given at the time the old queen was taken away. When the young queen had practically filled with eggs the combs from which the brood had emerged, six combs of all worker cells, filled as nearly as was possible with sealed brood, were given to such a nucleus. Three days later a super of sections filled with thin foundation was given, when the no-drone and current-year-queen talk said such made colonies would not swarm that year. In about ten days these hives became filled to overflowing with bees from the sealed brood given, and the bees were making a start in the sections, as there was a fairly good yield of nectar from the fields.

Some days later, when I was becoming enthused with this way of making colonies, which would be non-swarmers for at least one season, out came a swarm of monstrous size, the queen coming out with the last half of the bees in regular prime-swarm fashion. A careful looking-over of the combs which the hive contained gave no evidence of drones in any form whatever; but there were queen-cells with eggs and young larvæ in them. This was a damper on my enthusiasm, and the whole theory was finally spoiled by every one of the colonies I had made in this way swarming that year, with a single exception.

Those who still thought that there was

Continued on page 288.

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

Wherever bees here in Ontario had enough good stores last fall, they wintered in fine condition. Many beekeepers report heavy consumption of stores, and attribute it to a mild January. Clover is looking well at this date (April 4); and as there is an abundance of it this season, naturally we are hoping for a good crop of honey.

* * *

Talk about pluck, I think that picture on page 155, March 1, where a transferring operation is in progress, shows that virtue personified. How many women would want to be working like that with those thousands of bees crawling all over the ground, and over herself, as seems to be the case. Transferring will always be necessary, I suppose, to a certain extent; but at best it is a mussy job when done by the old-time methods. The times are rare when one can not transfer by simply putting the new hive on top of the box or other receptacle, allowing the queen to go above and occupy the good combs or foundation. As soon as she is above, slip a queen-excluder between the two bodies, and then in 21 days shake off the bees of the lower hive, doing as you wish with the combs, now empty of brood.

* * *

The spraying question is a live issue in Ontario again, especially in localities where fruit is grown extensively. Last week I was in the counties of Northumberland and Durham on a short Institute trip, and at different places I heard of owners of spraying outfits who said that they were going to spray right along, and, if necessary, pay any fines imposed. They said that the outfit is worth at least \$15.00 a day to them; and as the fine is very small, they can afford to pay it if necessary and keep right on at work. To make matters worse, some good fruit-men are not as sure as formerly that the spraying in full bloom injures the blossoms; and with a big acreage to cover they say that, if it were not for the bees, they would spray right in full bloom. It is a difficult question to solve; but there is no question that the best-informed men in the fruit industry are opposed to this spraying in full bloom, even if it were not detrimental to the blossoms, as they realize that the bees are necessary in order to insure best results in the way of fertilization. Something will have to be done in the near future, for this spring the chances are that there will be considerable friction in some localities; and if the law we have is to be

enforced, certainly amendments must be made that will make the fine more than nominal.

* * *

QUEENS MATE QUITE CLOSE TO THEIR OWN HIVES.

Mr. John McKinnon, writing in the *Canadian Bee Journal*, says that his Italian bees did some robbing from hives four miles distant, this last season, and also that some black queens six miles away were mated to Italian drones from his apiary. While I would not contradict these statements, yet it would need some pretty positive proofs to convince me that he is correct. For years, much buckwheat was grown within four miles of our home apiary; and while bees in the buckwheat section stored more than enough for winter each season, not once was a drop of buckwheat honey noticed in our yard. In said yard there were Italians, Carniolans, and blacks, so no "race" claims can enter into the matter as an explanation. As to distant mating, I can not speak so positively; yet all my observations along that line certainly go to show that the great majority of queens are mated quite close to the hives from which they issue. Especially is this so in so far as black bees are concerned; and usually with an equal number of black and Italian drones flying, the black chaps will come out ahead in the race, as any one who has bred Italian queens in a mixed apiary will testify to from sad experience.

Conversations with Doolittle—continued from p. 287.

something in the no-drone theory, still clung to the belief that swarming can be prevented that way, and so I tried many plans looking toward the prevention of a single drone being reared in any hive in their apiaries, they considering the prevention of the rearing of drones the greatest obstacle in the way, for it is the natural instinct of a strong colony of bees to rear a few drones when the colony becomes prosperous enough in early spring. It was found out that frames of all worker comb, or those of foundation having that size of cell, were not proof against drones, as some anxious colonies would get in a few cells in the corners of the frames, between the frames and some part of the hive; or, if thwarted in all these ways, they would even cut down a little patch of worker comb and build drone comb; or the queen would lay drone eggs in worker cells.

General Correspondence

THE SWARMING PROBLEM IN THE NORTH

Making Increase; Making up Winter Losses

BY E. D. TOWNSEND

The prevention of swarming when working bees for either comb or extracted honey is a matter which should be given attention earlier in the season than many suppose. It is a case where the old adage, "An ounce of prevention is worth a pound of cure," applies forcibly; for if one can get his bees strong, and still keep them free from the swarming fever until the opening of the clover or raspberry flow in June, with rational handling during the honey-flow, but little swarming should result.

A MILD SYMPTOM OF THE SWARMING FEVER.

One indication of the swarming fever is the early rearing of drones in spring. This symptom is not of a very severe type, as it will be noted that swarms with but a moderate number of bees rear drones the same as the more powerful colonies during the spring months. At this time the swarming fever is so mild that subsequent events or conditions will determine whether the colony will swarm or not during the season.

A CRITICAL PERIOD IN SWARM PREVENTION.

In the North the period of three or four weeks previous to the opening of the clover or raspberry flow of honey is a critical period—the time of our main surplus-honey flow. We have practiced for years the protecting of our bees either out of doors, in packed or chaff hives, or papering those wintered in the cellar, until after the danger of freezing nights was over, which in this location is from May 20 to 25.

We have a system of uniting our very weak colonies with our very best ones, setting one above the other, without excluder. To digress still further I will say that, at this uniting, stores are equalized—i. e., a weak colony containing considerable honey is carried and set either under or over (as my judgment suggests) a colony containing a normal quantity of bees, but short of stores, or *vice versa*. There are still some colonies not very populous that are worth saving. It will pay to protect these in some way during the cold period of spring.

How to carry the populous colonies of bees through the period of three or four weeks previous to the opening of the main honey-flow without their acquiring the swarming fever is the proposition in swarm control during the season. Swarming-fever prevention at this period is secured by giv-

ing the more populous colonies *an abundance of comb room* so that they will never feel the least bit cramped for room. This is the key to swarm prevention previous to the opening of the honey-flow. More and more each year we are practicing giving a set of empty combs to each good colony some little time previous to the opening of our main flow of honey in June.

We start out by giving sets of brood-combs where swarms have died out, or some where weak swarms were united the previous fall. As we never extract from these brood-combs, they usually contain considerable honey and bee-bread, which is valuable at this time.

EACH COLONY CARED FOR ACCORDING TO ITS INDIVIDUAL NEEDS.

If a colony is found in May with a good stock of bees, but which for some reason or other is short of stores to carry the bees over to the opening of the main honey-flow, we place, in this extra set of combs we are giving them, honey to supply their wants. Those stories of brood-combs which we give early are placed under the colony, while those given later in the season are placed above a queen-excluder (on top), for they are our regular extracting-combs.

While we strive to have our covers fit reasonably tight, thus preventing any considerable direct draft through the colony, the summer entrance should be used. In most cases this large entrance, coupled with a full ten-frame set of combs underneath, will prevent the swarming fever. A colony of bees free from the swarming fever is worth two colonies that are "sulking" at the opening of the surplus flow in June on account of the swarming fever.

The handling of the surplus receptacle during the honey-flow is worked on the plan of giving plenty of room during the first three-fifths of the season, or allowing the remaining two-fifths of the honey-flow for finishing.

HOW WE MAKE UP OUR WINTER LOSSES; ALSO HOW WE MAKE OUR INCREASE OF COLONIES.

After managing our bees to the best of our ability, without going to the trouble of shifting combs about from colony to colony, some few colonies will swarm unless we utilize them for increase. As our bees are mostly in outyards, where a part of them are left without a keeper each day during the season, on account of there being more yards than help, if the bees were allowed to cast many swarms a considerable loss would occur.

As I have already mentioned, the extra strong colonies early in the season were given an extra story under, containing a weak colony. Others were given sets of brood-combs containing more or less honey according to their needs, while still others were given sets of extracting-combs above an excluder. In case of the colonies containing two sets of brood-combs, or any divisions, for that matter, where sets of combs are available, we proceed as follows in increasing our number of colonies: The upper story is usually the one containing the main portion of the brood and honey; but it often happens that the queen has begun to utilize the lower story by the opening of the clover flow of honey. In case young brood is found in the lower story, all we have to do is to see that the queen is in the lower portion, put on an excluder, then a set of extracting combs, and, on top of all, the set of old brood and honey. In eight days the brood will be all capped over in the upper (queenless) apartment, and in two more days ripe queen-cells will be found. About one colony in ten will not build cells in their queenless brood above; but ample cells and to spare will be found in the other nine colonies to make up any deficiency in the tenth colony.

At the time of making the divisions, if cells are found, as in preparation for swarming, no notice is made of them unless there will likely be a virgin hatched before our next trip to the yard to finish up the increase ten days later. In this case a queen-excluder is placed under the body containing the cells, so as to be sure that the young queen will be in the very set wanted, or, in other words, not be allowed to roam over two sets of combs, making it necessary to hunt her up on the tenth day. On the tenth day the set of brood, now all sealed, containing either cells or a virgin, as the case may be, is given a bottom-board and cover, and is then placed upon a new stand and allowed to build up for winter.

If it is desired to make more increase than this one division, the newly made colonies can be divided in the middle, giving each half an equal portion of brood and honey, and seeing that each half gets a comb of brood containing one of the best queen-cells. Where the brood is divided in the middle, making two colonies out of the one set of brood, as set forth above, empty combs, or combs containing honey, should be used to make up the number necessary to fill out the hives, as foundation will not work so well in this place. With such small colonies, especially where there is no fall flow of honey, feeding will probably have

to be resorted to for winter stores. The above is our plan for making up winter loss where combs are available.

For increase, or any occasion where no combs are at hand, full sheets of wired foundation are used. The queen is found, and the card of brood, queen and all, is set in a hive body, and the remaining space filled in with frames containing foundation. The old hive is now set to one side, and the body containing the queen is set in its place on the old bottom-board. An excluder is now placed on top, then a set of extracting-combs, and the original hive placed on top of all for ten days, when it is given a permanent stand of its own, the same as when drawn combs were used.

This system of making up winter loss and increase is particularly adapted to out-yard work, as two visits is all that is necessary to do all of the work.

Northstar, Michigan.

THE SWARMING PROBLEM IN THE SOUTH

The Most Economical Way to Make Increase

BY J. J. WILDER

In this article I shall give some of my plans briefly; but allow me to say that no great crop of honey can be harvested here without close watch over the bees, and more or less manipulation of supers and frames. The extra amount required to control increase, however, is not so great.

No beekeeper should undertake these two great steps in our industry until he is familiar with the sources of honey within reach of his bees. He is then far better qualified to take up the work.

SWARM PREVENTION.

During a slow glimmering honey-flow, such as we have in the South during the summer or fall of the year, bees will not acquire the swarming fever if they are kept supplied with plenty of storing room. But during the spring months they seem to be naturally inclined to swarm, and will do so on the least provocation.

There is another fact noticeable about swarming. If, during the swarming season, there should happen to be one or more days of bad weather when the bees are confined to their hives, they seem to spend this time of leisure in preparing to swarm, and no doubt the greatest impulse for swarming starts under such conditions. In my location I may expect swarming to begin the first week in April. My first round in examining bees is made in February, and the second one during the first and second week

in March. On this round, all very strong colonies are elevated from their bottom-boards by means of two $\frac{7}{8}$ -inch strips cut 20 inches long, one placed under each side. This gives good ventilation from end to end, and allows the bees a good clustering-place about the bottom of the frames, which will protect the brood during cool nights, and allow plenty of ventilation during sultry nights, at which time they will most likely acquire the swarming impulse.

My brood-chamber consists of one eight-frame hive-body and a shallow extracting-super on top containing ready-built combs which are left on over winter, and which contain more or less honey; and if the queen is occupying this super of combs, another super is set on top, which gives the queen additional room. This super can be taken from some weaker colony, or there are usually some extra ones left on in the fall at each apiary for this purpose.

The third and fourth weeks in March another tour of inspection is made, and more strong colonies are treated in the same manner, and the weaker ones left for attention on the next round. The first ones thus treated are given a storing super; for by this time the eve of the honey-flow is at hand.

My third round is made during the first and second weeks in April, and at this time all colonies are treated like the first strong ones. By this time a little nectar is coming in, and the strongest ones are examined in order to see whether they have started queen-cells. This examination is made by tipping up the supers next to the hive-body enough to see well over the combs and also down through the combs below; and if any queen-cells are started they are torn out; but if not, the super is let back in position. If any work has been done in the storing super, another one is put on.

The fourth round is made the third week in April, and all colonies are examined for queen-cells as was done on the previous visit. By this time the honey-flow is in progress; and wherever a colony has started work in the storing supers, another super is added. Instead of placing it on top it is put under the other storing supers next to the brood-nest.

The fifth trip is made the fourth week in April, when all colonies are again looked over for queen-cells, as on previous visits, and storing room is added as may be necessary, allowing no honey to be finished next to the brood. By this time the bees are working in several supers, and there is little if any finished honey.

Another round is made a week later, or the first week in May, and all apiaries are worked as on the previous visit. The honey-flow is now at its best, and there is some finished honey which can be removed, and the packers started to work. About two weeks hence the honey-flow will decrease.

The second week in May another trip is made, and a few of the colonies in each apiary which have made the greatest effort to swarm are looked over; and if no sign of swarming appears we do not give the apiaries a general working, but add more storing room where it is needed. Then no more manipulation is necessary, for the bees have lost all desire to swarm, and will finish filling the supers.

INCREASE.

I make as much increase at the home apiaries as possible, for it is more convenient there, but a lot more of general increase is made at the out-apiaries. This increase is usually made at the time of our second or third round, and it requires but little extra time when every thing is in readiness.

In early spring, when we find a colony building queen-cells it is divided into two equal parts, and the queenless half is left on the old stand (if we happen to find the queen; and if not, both divisions are given combs containing queen-cells). Then the open space in the hive-bodies and supers is fitted in with ready-built combs, or frames containing full sheets of foundation. On our next rounds the divisions are examined, and the weaker ones are replenished with frames of sealed brood from colonies that can best spare it, and are given storing room as they need it. This cures such colonies of the swarming fever for the season; and as the divisions were made early, these colonies will store considerable surplus honey before the end of the spring honey-flow. Then more general increase is made near the close of the summer or fall honey-flow; but at this time there is no natural inclination to swarm, and nine or ten days after the divisions are made (which is done as in spring) we make a special round and see that all queenless divisions have at least one good queen-cell. At the close of the season, when we put the bees up for winter, if any colony is queenless we unite it with a weaker colony. Only the strongest colonies are divided, and those that are heaviest in stores, so that no feeding will be necessary. Thus our general increase is made from our very best stock. The increase at the home yards is made in like manner by dividing up the strongest colonies from time to time throughout the season; but here we give the queenless divi-

sions ripe queen-cells from our very best stocks; and when there is no honey-flow on we resort to outdoor feeding, and thus our off grades of honey are utilized. All queens are given all the room they can occupy by inserting empty combs in their nest; and as soon as one well occupies six or eight combs the colony is again equally divided, and so on throughout the season. Such increase may be distributed around to out-apiaries at any time during the year.

Cordele, Ga.

THE SWARMING PROBLEM IN THE EAST

Some of the Common Methods of Control Discussed; Natural Superscedure During Swarming

BY J. E. CRANE

Perhaps to no one subject connected with beekeeping has more thought been given than to the control of swarming. With the production of extracted honey this is comparatively easy. By raising one or two combs of brood into a super of empty combs above the brood-nest, filling their place with good empty brood-combs early in the season, and keeping the colony well supplied with room, there is usually little trouble with swarming.

It is quite otherwise with the production of comb honey, for the brood must all be kept below, and the brood-chamber crowded, in order to force the bees into the supers.

Destroying or decapitating a large amount of worker brood has been recommended as a sure preventive of swarming; but the practice is too expensive and disgusting to be thought of.

If one opens a large number of colonies week after week he may be surprised to see how many of these will have eggs in queen-cells, and sometimes young larvæ for three or four weeks, and yet never swarm, so evenly are the forces of the hive balanced in favor of swarming or opposed to it. We may take a hint from this, and use all those measures that tend to discourage swarming, such as giving an abundance of ventilation, shade, room for the queen to lay in the brood-chamber, super room for storing surplus, with bait sections, as well as the proper manipulation of the supers to stimulate to the utmost the storing instinct. I have also found that it is a decided help to destroy drone brood where there is much of it in the hive, or it will sometimes be found where there are many old combs. But after all is done that one can do to discourage

swarming, if the season is good, honey abundant, and the hives filled with brood, there will probably be many colonies that will prepare to swarm.

As fast as such colonies are found, prompt measures must be taken. If the colony is strong with a vigorous queen I would shake at once on clean worker combs. If these contain some honey it is just as well; and if half full of sealed brood I am inclined to think it is even better; but I do not often find the latter. When the bees enter the hive, or before, return to them the supers from the hive they have occupied. The absence of any unsealed brood will most likely cause them at once to give up any desire to swarm; and the half-filled supers will stimulate their storing instincts, and you will have them under control for the season unless the flow of honey is of long duration.

If you find a colony that is not strong making preparation to swarm, do not shake, as it will be of little value if you do, unless you take pains to nurse it and build it up; and even then it may prove to be an unprofitable venture.

If the queen from such a colony is old or not prolific, the best thing to do is to catch her and destroy her at once. It is not always easy to find a queen during the swarming season; but if you have a queen sieve it is not usually a long job. Then destroy all sealed queen-cells, and in eight days again destroy all sealed cells, and in another seven or eight days give a virgin queen. It is well to take from the brood-chamber any combs not occupied with brood, if possible, and to fill up with combs of mature brood. In this way work may be begun in the supers within a short time.

If I find a colony preparing to swarm with a queen of good age, and yet a colony which for some reason may not have a large number of bees, I often take the queen away, with perhaps twice as many bees as necessary to care for the brood, and place them in a new hive with an empty comb on one side and a comb of honey on the other side of this brood-comb. I set the hive aside, and throw a little grass or a few weeds over the entrance, and it will take care of itself. Most of the old bees will go back; but enough will remain to make a good beginning for a new colony.

The swarming season is the natural time for the superscedure of old queens, or such as have become exhausted by excessive prolificness. Queen-cells are started, and, when of proper age, the colony swarms; and the queen, unable to fly, drops to the ground and is lost. The colony returns to the hive,

"Playing with 'em." From Amos Harker, Cambridge, Iowa.

awaits the hatching of a young queen, and, when she is old enough, swarms again with her. A young queen also takes the place of the old one in the parent hive. Now, if we shake a colony preparing to swarm with an old or poor queen on empty combs, or even start a nucleus with such a queen, we shall be almost sure to meet with disappointment, for she will most likely fill a small patch of comb with eggs, and disappear; and queen-cells are started on these in order that the colony may secure a queen to replace the one which the bees recognize as no longer of value.

But what should be done with all the combs of brood which have been taken from those colonies which were shaken on empty combs? Well, that is a part of my story. Early in the season there are usually some colonies that are not strong enough to begin work in supers. Indeed, not more than five or six combs of brood will be found in them, and in some it may be even less. When one has plenty of surplus combs of brood he can take out the empty combs or combs of honey from these colonies and replace with combs of brood; and these backward colonies, instead of spending the whole season in building up and getting ready for business, will soon be able to enter the supers and yield surplus.

The combs removed from these weak colonies can be utilized by giving to colonies preparing to swarm which are fit subjects

to shake. Brood can also be given to any nuclei you may have made, thus building them up into good colonies.

But how about increasing your stock if you do all you can to prevent swarming? In almost every yard there are some colonies that are very forward—more so, even, than desirable in order to secure the best results in surplus. I know of no better way than to take from such early in the season a comb of hatching brood and bees—yes, more than bees enough to care for it, for some of them are likely to return to the parent hive. Then confine the bees for a day or two in a new hive, or throw weeds over the entrance. Give them at the same time a comb of honey and a brood-comb, and a day later give them a queen-cell nearly ready to hatch. If all goes well, in a few days there will be a good nucleus with a young laying queen; and if brood-combs are supplied as fast as their strength will admit you will soon have a colony capable of storing considerable surplus in case the season proves to be favorable.

If you have no maturing queen-cells, take the first colonies that prepare to swarm, and divide them into three or four strong nuclei, giving all except the one that has the queen a queen-cell already built on the combs; and, as soon as the young queens are laying, build up as fast as you can. Such colonies gave us a good surplus during the season of 1912. These methods not

Hiving a swarm in a soap-box. From F. E. Bornemann, Bay City, Oregon.

only favor increase, but at the same time help to keep down natural swarming.

The rules given above are for those who handle their bees often, and depend on their manipulation to control swarming. Of course, queens' wings must be clipped; and while it gives one perhaps about as much work as to depend on natural swarming, it saves a lot of time. I forgot to say that if, at any time at the close of the day, you have on hand a surplus of brood-combs, they can be put on top of some weak colony or placed in some colony that may be loafing, making them care for the brood.

For those who have but one yard of bees, and do not care to handle them more than is absolutely necessary, and for those who prefer to let their bees swarm naturally, I know of no better way than to hive early swarms into hives filled with dry combs, and, after eight or ten days, run the new swarms into those that swarmed first. In this way second swarms are largely prevented, all are kept strong, and the largest amount of surplus secured. While this does not wholly control swarming it does control increase in a very satisfactory way.

If you lack empty combs, place over strong colonies as many supers full of frames filled with comb foundation as you are likely to need. The bees will draw out the foundation into comb more economically than in any other way. New swarms or shaken swarms do not, as a rule, take kind-

ly to foundation so far as my experience goes, and often desert a hive filled with it when they will accept half-drawn combs with the greatest pleasure.

Middlebury, Vt.

CHOOSING A LOCATION FOR AN APIARY

The Importance of a Near-by Source of Nectar and Pollen in the Spring

BY J. L. BYER

At this season of the year many, no doubt, will be considering the matter of starting apiaries; and while the experienced beekeeper needs no advice along this line, a few hints to beginners may not be out of place. Naturally, when thinking of starting an apiary of any size, the first thing that will be considered is the prospects of having enough honey-producing flora to produce a crop of surplus honey; for, no matter how many colonies of bees one may have, and no matter how strong they may be in numbers, if there is no forage for the bees at the time surplus should be gathered, all the previous labor of the beekeeper and of the bees will amount to naught. However, situations of that nature are scarce; and, as a rule, if one has bouncing big colonies at the opening of the clover flow he may safely count on getting at least a partial crop, one year with another.

Granted, then, that there is enough clover,

basswood, or other staple sources of nectar to give promise of a yield of honey, the next thing to be considered is the spring-feed proposition. Indeed, after a number of years' experience I am a bit doubtful if this question should be designated by "next" or by "first," as every year I am more than ever convinced that a good spring location is about as essential as any thing in so far as the getting of a crop of honey is concerned. One thing is certain to me, at least; and that is, that I would take an ordinary clover location coupled with a first-class spring locality in preference to one having a superabundance of clover, but with practically no spring feed. It is very essential to have this spring feed right *near* the apiary if possible, as in the trying changeable weather of the spring season many bees are lost at a critical time when all are needed, if they have to fly long distances to the alders, pussy willows, etc., in search for early pollen and honey. If I had the choice of two locations, in one of which there was abundance of spring feed within half a mile of the apiary, while the clover and other summer pasture was two or three times that far off, and the other one with abundance of clover right near the yard, but the spring feed scarce and a long distance away, I certainly should prefer the first one described, every time. I have had, in the past, locations of both these kinds, and *always* the ones with spring feed near by have given best results.

Having decided on the section where you

want to have an apiary, the next thing is to find a suitable spot to place the bees. Shelter is very desirable; but unless it is one of the natural kind I would just as soon have none at all. In fact, while I like yards sheltered, for more than one reason, yet right near us I know of apiaries that have wintered outside, right in the open, year after year, and the loss has been but little heavier than in more sheltered apiaries. Apiaries sheltered too much, and not in the right way, are like a two-edged sword—apt to cut two ways. Bees may be enticed outside by the sunshine, only to be chilled to death by cold winds; whereas the same hives out in the open would have the cold air circulating around them so that the bees would not leave at all in such treacherous weather. In the past I have been having most of my yard in orchards, and in many ways these are about as desirable locations as one can find. Objections are that snow usually drifts badly among the trees; and in many orchards the bees are too close to dwellings, cultivated fields, etc., and at some seasons they are apt to make trouble for those who own the property the bees are on. Of course I am now speaking from the standpoint of out-apiaries. I never like to have the bees give any trouble if it can be avoided; and so when starting a new yard or moving one of these I now have, I am trying to have the bees placed in an out-of-the-way position where they will be no bother to any one, and where I shall not be placing any de-

A new location for one of J. L. Byer's out-apiaries. The yard is sheltered on three sides by a cedar swamp, and the buildings break the force of the wind at the one open side.

Lone Tree apiary of Bell E. Berryman, Central City, Nebraska. This apiary of 190 colonies was built up from 55 weak colonies in the spring of 1912, and yielded 9000 lbs. of honey.

pendence on any one at the place looking after them.

While it is essential to have some one pay occasional visits to the yard to see that all is well in so far as general conditions are concerned, such as hive-covers being all on, etc., I have found it best not to depend on anybody watching for swarms, etc., as I then know what I have to do, and experience has proven to me that this is the best policy.

Water for the bees in the spring months is a very important matter—in fact, one of the necessary things to see to if you wish to avoid heavy losses of bees, as will surely result if they have to travel a mile or more for their water; for assuredly they must have water, and lots of it, if brood-rearing is to go on at the rate it has to in order that the colonies be strong enough for the main honey-flow in June. Many arrangements have been suggested, and actually used, for providing water right in the yard; but if the bees can get it near the apiary in a nicely sheltered position they seem to prefer it to getting it from a barrel or other arrangement fixed up for them. While one can fix up a place for the bees to get water right in the home apiary, it is a different proposition in an out-apiary, and—well, to be perfectly frank I shall have to confess that I have to let the bees get their water the best they can, as it would be a lot of work to drive around to a number of yards, filling up barrels, etc. At the same time, I am free to admit that this work would pay, if the bees had no

access to water quite near their hives. At each of my yards at present, water is quite near, so I am saved the trouble of supplying it artificially.

This spring I have to move one of my apiaries; and as the location I have selected seems to be about ideal I have taken a picture for the purpose of illustrating what I have been trying to describe as the desirable features of a good location. As will be noticed, the honey-houses have already been moved, and are standing upon temporary foundations till the snow goes in the spring, when the buildings will be lowered and leveled, and placed on cedar blocks. The bees will not be moved till after they have had their first flight. They are wintering outdoors half a mile from where they are soon to be moved. Two empty hives, one on top of the other, are shown in the open space, and this spot will be about the center of the apiary when bees are placed. The cedar swamp shown will be on the north, northeast, west, and southwest, while the only open space will be at the southeast. On this side the buildings are placed end to end, not so much for protection as to save fencing, as I shall have to fence the plot to keep stock from roaming among the hives and upsetting them. This piece of ground (about half an acre) is level, and high and dry; and while the shelter is a little *too* good(?) to suit me, still, it is a different matter from a board fence, as bees will not be tempted to fly over a wide space of trees as easily as they can go over a high board fence, to drop at

FIG. 2.—Hiving the swarm after it was carried home in a cloth.

once, never to return. While, as I have said, the ground is high and dry, yet right near where the bees will stand the ground slopes abruptly toward the swamp, and there the soil is springy, with the water oozing out all summer. Here the bees can get water in a sheltered location, and never have to fly 50 feet from the yard. The nearest cultivated field is about 20 rods away on the east side; and as this is the only side of the apiary that has cultivated land near, naturally we are hoping that all danger from that source will be reduced to a minimum. As to spring feed, it starts right at the south end of the apiary; and the bulk

of all there is in the vicinity is within half a mile of the spot. Abundance of alsike near by, with about enough buckwheat grown to supply winter stores each season, about completes the description of this location.

Mount Joy, Ont., Canada.

9000 POUNDS OF COMB HONEY FROM 55 COLONIES, SPRING COUNT

BY BELL E. BERRYMAN

I am sending you a photo of one corner of my apiary of 190 colonies. In the winter of 1912 I lost 45 colonies out of 100. My 55 colonies left were all weak and short of stores in March. I fed them liberally, and increased them in June to 190 colonies by dividing, and harvested 9000 lbs. of section honey. The largest yield from any one colony was 240 lbs. of section honey. I lost none last winter, as the winter was very mild compared with the one before last.

Central City, Neb.

CHASING A RUNAWAY SWARM 2½ MILES

BY G. FRANK PEASE

Bees swarmed here last summer as never before in my experience, even when the flow of nectar was slow. The pictures shown are of a runaway swarm from one of my hives. I chased the bees 2½ miles, and brought back the swarm on the limb on which the bees had settled. The limb was thrown over my shoulder, with a cloth

FIG. 1.—A runaway swarm that Frank Pease, of Marshall, Michigan, chased for 2½ miles. Photo was taken from the top of a building.

FIG. 3.—Enough bees to pay for the 2½-mile run.

wrapped around the bees. The swarm, Fig. 1, extended for three feet along the limb.

A tinner made the smoker on top of the box, from heavy copper. The bellows was from a Clark cold-blast smoker.

In Fig. 2 is one of my glass and tin combination covers. I pulled a string to take the picture.

BEES POISONED BY A BLACK SPIDER.

I was at one of my hives this morning, and saw a black spider killing bees. He ran toward the entrance, and two bees pounced on him. He held them off the length of his legs, and they died inside of a minute without his even biting them; then he dragged them back to a pile of dead ones which he had killed—forty or fifty of them, and seemed to be sucking the honey from under their throats. Others flew toward him and merely touched him a little, and they seemed to be stupefied. He must have ejected poison toward them, such as I have smelled when a spider has been near my nose. The bees would cease to struggle in a very short time, and could not get their sting near the spider as I expected them to do.

Marshall, Mich., June 13.

ALEXANDER PLAN FOR MAKING INCREASE CARRIED OUT TOO LATE

BY M. J. KAUFMAN

About a month before the time this picture was taken I started with an eight-frame colony and a select queen. I fed the

bees steadily from the time I got them, which was the 3d or 4th of May, 1911; and as the colony became very strong I decided to divide it. I divided them according to the Alexander method, and this was the lower hive. When they swarmed, which was three or four days after I had separated them, they had drawn out only five of the frames from the foundation. They had plenty of room, and the weather was not unusually hot. I had given them a select queen; and, not having another hive at the time, I cut out the queen-cells they had built; and the queen being clipped, and not being able to get away, the swarm returned of its own accord. Notice that I had raised the super as shown in the picture, as I thought it might afford ventilation if the bees thought it was too hot in the hive.

New York.

FORMING NUCLEI TO PREVENT SWARMING

BY R. M. SPENCER

When the swarming season begins in March we go over all the hives once every eight days, cutting out all cells, making nuclei, or, where colonies have good stock and cells, we often make straight division. When we are able to get the young queens we take frames of bees containing about three times as many bees as we want, and shake them in front of the small nuclei on the ground, allowing them to run in and to cluster on the several frames of brood pre-

viously given the nuclei. About a third of these bees are young nurse bees, and will stay with the brood. This method avoids any trouble of closing up or opening later. Every eight days we again shake a frame of bees in front of each one of these nuclei, thus helping the nuclei and holding the full colonies in check from swarming.

BEES SLUGGISH BEFORE THEY SWARM.

One of our great troubles in this locality

is spring supersedure of queens; and in many cases this causes swarming when it would not happen otherwise, the breeding season being so long that many of the queens fail in the spring of the second year. Often by simply opening hives and taking out frames of bees one can tell by the action of the bees whether there are cells in the hives. The bees are always filled with honey, and act sluggish when making prep-

Swarm returning to the hive because the queen was clipped.

FIG. 1.—A swarm that chose a very convenient clustering-place.

arations for swarming. When bees are active on the combs there is little danger of swarming. By using this method of judging when colonies are preparing to swarm I have often gone over 500 or more colonies in a day, and very seldom make a mistake as to whether a colony will swarm within a week.

GOOD VENTILATION AN AID IN PREVENTION OF SWARMING.

Another great preventive of swarming, as all beekeepers know, is ventilation. All our hive bottoms are loose, and have full-width entrances on both ends. As soon as warm weather comes, both of these entrances are opened full width. I am cer-

ence with a swarm a short time ago proved this quite conclusively.

On Friday, May 28th, my brother-in-law phoned me from the Cashel yard that a large swarm had come out, and that he had caged the clipped queen and had let the bees go back to the hive. I felt pretty sure that the bees were superseding the queen, and knew that there was danger of their coming out any time with a young queen, departing for parts unknown. However, I could not get over before the following Monday, so I let them take chances.

When the family were at church Sunday I suspect the colony swarmed again and clustered in the top of an apple tree in the apiary. Any way, Monday forenoon the swarm was noticed leaving the tree and starting off north. My brother-in-law followed them, and they went so slowly that he just had to walk to keep up with them, notwithstanding the fact that the day was calm with no wind to hinder their flight. They went less than a quarter of a mile and alighted on the top of a rail fence. Fig. 1 shows the swarm nicely clustered on the rail fence. Fig. 2 shows how the rail was lifted

FIG. 2.—Shaking the cluster into a hive.

tain that this prevents swarming to a great extent.

Nordhoff, Cal.

HIVING A SWARM CLUSTERED ON A RAIL FENCE

BY J. L. BYER

Before a swarm leaves the place where it has clustered after swarming, it is thought that, as a rule, scouts are sent out, and a place is found before leaving. This may be the rule, but, like all other rules, there are exceptions to the rule, and a bit of experi-

FIG. 3.—Safely hived. (J. L. Byer sitting on the fence.)

from the fence and the swarm gently jarred into the hive. The picture in Fig. 3 was taken after the bees had been shaken into the hive; and if ever a crowd of bees were glad for a home they surely were, as they settled down right at once with that home cry so well known to the beekeeper.

My nephew, Leslie Williamson, happens to have a camera, and that explains how we got the pictures. By the way, I rather smiled when the picture was shown me, as I am perched on the fence in Fig. 3. It is rare that I wear a veil except in extracting time, and there was no need of one at all under the circumstances, as the bees were not at all cross. I had put it on when first going over to where the swarm was, and had forgotten all about it till after the camera had snapped.

Mount Joy, Ont., Canada.

SWITCHING THE HALVES OF A DOUBLE BROOD-NEST TO CONTROL SWARMING

BY J. A. YEOMANS

In the June 15th issue for 1912 I had an article, p. 366, concerning some experiments I have been making with the view of reducing swarming and at the same time increasing the production of surplus honey. I was much pleased to hear from beekeepers from all sections, showing their interest in these experiments. One man in particular reported as having worked along the same lines with results and conclusions the same, so far as he had progressed.

The summer of 1912 was a poor one for honey production in eastern Washington.

Warm summer weather was a scarce article. A few warm days would be followed by a spell of cold or rainy weather that drew on the surplus gathered by the bees during the warmer period. Some of my beekeeping friends reported practically no crop, and at least one said that he feared that not enough was on hand for winter stores. My crop was 65 pounds per colony, spring count, which I considered satisfactory under the conditions.

During the season I tried some experiments

which I am confident cut down my yield somewhat. For instance, I was anxious to see how early I could raise the "hatching story" of the brood-chamber and get the bees to start work in the supers (supers placed below it and above the laying story). I therefore tried this arrangement very early, before the hive was at all crowded, and before there was any real need of it. In fact, the result showed there were not enough bees in the divided colony to generate sufficient heat if weather turned cold.

The bees started work at once in supers (in which I had placed some bait sections); but in a few days the weather turned cold and rainy, and honey-gathering was stopped completely for several days. The field bees having all gone down from the hatching story, leaving only young bees in it, there were not enough left to cover all the brood, and some of it was chilled and killed. In spite of this setback the colony built up very rapidly. I should not have commenced switching so early. I feared the above would happen, but wished to try it any way. If the hive had been full of bees the result would have been different. I did not wait until the colony was strong enough.

The results of the past year convince me that the principles involved in this system are right. I expect and hope the beekeeping fraternity will improve on the details.

For the benefit of those who may not have the June 15th number, 1912, I will repeat in a few words the principles of the system, and will then try to answer the questions that have come to me from all sides. I have had letters from California, Oregon,

Wisconsin, Alabama, Pennsylvania, and one from Switzerland.

First, the only special equipment needed is a wire screen with a Porter bee-escape. This should be bound with strips of wood of sufficient thickness to give bee space above and below. A friend of mine, Dr. R. E. Shanks, of Spokane, has made an escape which is a great improvement on the crude ones I used in my experiment. Through his courtesy I enclose photos of these escapes. Dr. Shanks has been following this system for two years, and, although a beginner in beekeeping, he has had no swarming. The wire screen should be the full size of the hive used, so that the heat of the lower part of the colony will rise into the hatching story, and so that the hive odor will remain the same. Fig. 1 is a front view of the screen used.

The Porter escape is cut off just in front of the round hole in the back end of the top of it. It is then imbedded in a strip of board crossing the front of the screen. A passageway is then cut through the frame out to the open air in front, and a plug made which should be used after the first 24 hours after a switch of stories is made.

When the plug is out, a piece of super section should be slipped in, closing the opening to the lower story. The light which enters through this opening will attract and empty the hatching story of all field bees in a few hours. If the opening is not closed in a few hours, many of them will commence to use it as an entrance. After 24 hours the slat should be taken out and the plug inserted, so that all bees entering the escape will go into the lower story and not be able to return.

Photo No. 2 is the top view of the escape-screen and No. 3 is a bottom view. From these views I think any beekeeper will catch the principles involved.

FIG. 1.—Front view of Yeoman's screen escape-board. The plug used is shown standing up on the screen.

Several have asked me if the plan would work with the ten-frame hive. I use the ten-frame Danzenbaker, and feel sure the system will work with any size of hive. I now winter my bees out of doors in double brood-nests. Yesterday (February 16) the temperature rose to 51 degrees, and the

FIG. 2.—Top of screen—next to bottom of hatching story.

bees had their first flight since fall. If I did *not* winter in double brood-nests I would put on a second brood-chamber as soon as the bees commence to build up strong in the spring.

A SYNOPSIS OF THE PLAN.

As soon as surplus honey commences to come in, or if there is any sign of swarming (or if a new beginner is not familiar with these indications, when both stories are well filled with bees) raise the upper story and put a super of sections below the upper, or "hatching story." At the same time (or 24 hours later, which I find is much easier because the field bees have gone below and can not get back, thus reducing the number of bees in the upper story, and making it much easier to find the queen) remove the queen to the lower brood-nest, which we call the "laying brood-nest."

Ten days later, switch brood-nests after cutting out any queen-cells which may be started in the "hatching story." This makes what has been the hatching brood-nest for the past ten days the laying brood-nest for the next ten days. The bees hatched during the past ten days, and the honey and pollen used during this time have emptied thousands of cells ready for the queen to lay in, and this she promptly does as soon as it becomes the bottom story and she is placed in it.

This switching keeps the queen laying

continuously, removes her and the field bees from all brood and eggs every ten days (virtually the same as swarming), and prevents brood-nests from becoming clogged with honey. The supers remain constantly in the same relative position to the hive entrance, and the field bees are not interrupted in their daily habit of storing the surplus.

Repeat this operation every ten days through the swarming season, which will vary according to locality, or introduce (24 hours after switching) a young queen to the top or hatching story. As this story contains young bees only, it is an ideal condition for introducing a new queen. Then kill the old queen the next time you switch, and leave the hatching story on to hatch out entirely.

I think that most beekeepers agree that a young queen rarely swarms during her first season, so you will by this means, as soon as a young queen is introduced, end the danger of swarming in nearly all cases.

A Pennsylvania friend asks about using a hive filled with foundation and placing it below an old hive in order to get two brood-stories to start the plan. I should prefer to divide the old brood-nest as nearly equally as possible, and fill out both stories with frames of full sheets of foundation.

FIG. 3.—Lower side, next to supers.

I like to have both "hatching" and "laying" stories have about an equal amount of brood in them. Also, by dividing the old brood-nest equally there will be enough old combs containing pollen and honey to supply the nurse bees in the hatching story for the ten days they are shut off from all outside supply. A supply of honey and pollen sufficient for this period of time must always be on hand in hatching story.

Spokane, Wash.

COMB HONEY FROM A SHORT FLOW

Worker Comb from Starters

BY A. V. SMALL

Last summer the swarming impulse was above normal; and as our flow is usually of short duration, comb honey could be secured only by a plan that would satisfy the swarming desire, and at the same time force the June flow into the supers.

The plan which gave me the best results was to shake the bees into a contracted chamber of starters. This was done in the early part of the flow. The colony was left on its old stand, and I merely took away the brood, contracted the brood-chamber to the space of six combs, and gave the bees a set of starters. In the colonies treated there was considerable comb in the supers; and in order to establish the brood-nest I placed a frame partly filled with young brood in the center of the contracted brood-chamber, filling out with five frames of starters. This was the first hive tried.

There was a good flow on the day the work was done, and the bees worked right along as though no change had been made. The queen began laying in the empty cells in the frame of brood I had placed in the center. The bees began to work on the starters, and every thing went well except that I had established the brood-nest, but had not provided the storehouse for pollen. The brood comb that was used had been taken from near the center of the hive, and was almost free from pollen. In the average brood-chamber the two outside combs contain nearly all the pollen in the hive. If the queen is good they are about half filled with brood and the rest is honey. These two outside combs were gone, and the first day's pollen went with the honey up into the sections.

The next colony that built cells I shook, contracted the brood-nest to six frames, leaving them their two outside combs and filling in the center with four frames of starters. In this case the pollen storehouse was un-

disturbed. A bee coming in with pollen could go to the outside comb where it had been in the habit of going, and unload as usual. There was not a single cell of pollen in sections over brood-chambers where the outside combs were left in.

The surplus honey went up into the sections, as the two outside combs were nearly filled to start with, and the four frames of starters in the center were occupied by the queen almost as fast as they were drawn out. This gave us four good worker combs from starters, for it seems to be a fact that the bees will build worker combs as long as the queen keeps filling them with eggs. This is the reason it is necessary to contract the brood-chamber.

If the bees had been given eight or ten frames of starters they would have drawn them out faster than the queen could occupy them, and a large amount of drone comb would have resulted. Then, too, as soon as the bees got ahead of the queen a good deal of honey would have been stored in the brood-chamber. This is the reason one must use starters when following this plan, instead of full sheets, if he is to get the best results. The full sheets are drawn out too fast.

In a week or ten days from the time of shaking, these combs will be drawn out and filled with brood. At this time, if one should give four more starters he *might* get worker comb; but this can not be depended on, and it is more desirable to fill out the brood-chamber with full sheets or with four of the frames that were taken away at the time of shaking. These frames will be practically all sealed now, and a few frames of hatching brood are desirable at this time in order to keep up the strength of the colony.

Worker combs can also be built in weak colonies, but they are very apt to be round-bottomed, with the lower corners incomplete. The following year this corner space is usually filled in with drone comb, making an undesirable frame.

Where starters are used with shaken swarms, as described above, the combs are full and square at the corners, having all the appearance of foundation-built combs.

As a word of caution, put on supers with *bait sections* as soon as the colony is strong enough to warm them up; and be sure there is some work being done in the supers at the time of shaking. The brood from the first colonies shaken can be placed above queen-excluders over the colonies one expects to shake next. Within ten days, about half of this brood will have hatched, and the other half will be sealed. If one wants increase he has merely to set this hive body

of sealed brood and bees on a new stand, and in a *few hours* give them a ripe queen-cell or a queen. This is one of the most satisfactory methods of increase I have ever tried.

The colonies over which this brood was placed are now ready for shaking.

Colonies strengthened in this way just at the beginning of the flow usually give me the best results in comb honey. While I have spoken of leaving this brood over the colonies ten days, a week is long enough, and gives three more days of flow for the sections. The brood from the colonies last shaken can be placed over colonies too weak to work in sections; and if increase is not desired the combs can be left over these colonies to receive what surplus they may make.

North Topeka, Kans.

THREE SWARMS IN ONE HIVE

BY A. G. LUCIER

It may be interesting to know how the bees got on the top of the hive as shown in the illustration. Hives No. 1, 2, 3, in a row, were preparing to swarm at the same time. One morning No. 3 cast a big swarm. The bees were hived in the usual manner as practiced with clipped queens. The very

Three swarms that united with the bees in one hive, making a colony too large for the hive.

An August swarm that built comb in the open.

next day they came out again: and, finding that their queen could not accompany them, instead of going back to their own home they went into hive No. 2, and in a few minutes came out again with the bees in that hive, and repeated the process as before stated, but went into hive No. 1 with the bees from No. 2. The weather being rather warm, the cover of the hive was lifted to ventilate. There were so many bees when the three swarms united that they fairly boiled over, as shown in the photograph.

Powell, Wyo.

AN AUGUST SWARM

BY A. B. GILES, M. D.

I am sending you a photo of a swarm which came out of a hive on the 27th of last August. They clustered in an apple tree, built comb, and had some brood. This picture was taken Oct. 13 by one of my neighbors, Mr. R. J. Clemmitt. I took 48

sections of white honey from the hive from which they came. It is remarkable that they swarmed so late in the season that it was a first swarm, and that they stayed so long in the open.

Forest Park, Md.

SWARM CONTROL—INCREASE AND DECREASE

BY RALEIGH THOMPSON

If a beekeeper desires moderate increase and a crop of honey he should first let his bees swarm, and then set the new colony on the old stand with the old colony by the side of it. In four days he should remove the old colony to a new location, put on a queen-trap, and wait for the second swarm, which will issue in from nine to fourteen days from the time the first swarm came out. He should then catch the virgin in the trap, which will prevent the swarm from leaving, for a young queen is very gay. The trap should not be removed until the bees begin to return. Then the old hive should be removed, and another one put in its place. Put the trap on this hive and let the queen loose through the hole in the trap for that purpose. Provide for the bees a frame of eggs and larvæ.

Take the old colony to a new location, and the next day divide it into as many colonies as can be supplied with queen or good cells. Give them a frame of eggs and larvæ. It makes them feel more at home. One should remove all supers from the first colony at the time it is hived. This is the best plan for the novice, and I think for older beekeepers as well, for there are very few queens that will beat swarming queens.

THE SHAKEN-SWARM PLAN.

Now for swarm control. I use the shaken-swarm plan given in the A B C and X Y Z of Bee Culture when I do not allow natural swarming, only I go a few steps further. I set the old hive by the side of the new colony, and in six days I put on an entrance-guard and shake the bees into the new colony again, leaving only enough to take care of the brood and queen. One must be careful if it is a natural swarm or he will find one or more queens on the guards. Now save the best cell or queen, and destroy all the rest if they are not needed elsewhere. Set the old hive on the other side of the new one, leaving an entrance at the further corner. In four days more move it to the other side, leaving the entrance at the further corner again. If it is a shaken swarm, one must raise queens for the hives, for a queen made by a shaken

One of J. M. Buchanan's outyards standing on the site of an old Yankee fort near Franklin, Tenn.

swarm is of no use. Now, if one does not want any increase, leave this old hive by the new one; and, after the flow is over, work the old queen-hive into the new queen-hive.

If I wait a little too late I use the paper plan of uniting, killing the old queen first. The best plan is to remove all the brood from the old queen to the new one every fifteen days as long as there is brood to move, for the old queen and bees are worthless, as they are all old, and the hive with the young queen is sure to winter, for the bees are all young, and there are plenty of them. The old hive and combs may be used the next year. These plans are applicable to a home yard rather than to an outyard, unless the out-apiary happens to be within a few miles of home.

If one has more bees than he wants to winter, he should double up, following the paper plan. If he has a choice of queens he should kill the undesirable one. If he has no choice, he should pay no attention to the queens. The bees will take care of that part of it. In southern Indiana I win-

ter them in two ten-frame stories, and they are boiling over with bees when the flow comes—about May 20.

Put all of the brood and bees into one hive, and put on one super of sections with full sheets of foundation, and another on top of this with drawn combs or one super. Just as soon as the bees begin to draw out the foundation, raise it up and put another under it. If the brood-chamber is not full of brood, use only one super; but in order to secure the best results it should be full. Put an excluder on some of the weak colonies, and stack the empty combs on them about three to the hive, for use later on, for part of these colonies will swarm within ten or twelve days.

One should put the sealed brood in the center of the hive—that is, if he has a hive full. If not, he should put empty combs in the center. If sealed brood is placed in the center, as soon as the brood hatches the queen will fill the cells with eggs and put more honey in the super. If one does not put eggs and unsealed brood on the outside,

when the sealed brood hatches they will fill the combs with honey, and there will be less honey in the supers, and more swarming, for the bees will always fill the outside combs with honey if they get a chance; and the longer there is brood in them the better.

Underwood, Ind.

OUT-APIARY ON THE SITE OF AN OLD FORT

BY J. M. BUCHANAN

I am sending a photograph of one of my outyards, which, in its location, is somewhat unique. On the summit of a hill, overlooking the town of Franklin, where, fifty years ago, was fought one of the bloodiest battles of the war, stands an old fort, once guarded by Yankee bullets, but now garrisoned with Dago stingers.

The apiary occupies the site of this old fort, which at present consists of a level spot partly surrounded by a bank of earth in the form of a horse-shoe, with the open end toward the south, thus providing an excellent windbreak for the hives. Part of this embankment can be seen in the picture. I have a nice honey-house and storeroom here, built so that it can be taken apart and moved. The apiary is easily reached with the automobile, which, by the way, we find indispensable in out-apiary work.

This yard contains at present fifty hives, run for extracted honey. It is surrounded by extensive blue-grass pastures, which are white with clover bloom during May and June. There are several groves of locust near by, and this forms one of our chief sources of honey. The locust honey is water-white, and of fine flavor, and slow to granulate. It blooms about the last of April; and if the weather is fair it yields quite heavily. During this flow last spring a colony on the scales made a net gain of 100 pounds in ten days.

Franklin, Tenn., Dec. 19.

IN MEMORIAM OF PAUL MICKWITZ

BY R. MICKWITZ

[The unfortunate subject of this sketch was at Medina in the winter of 1907-'08, learning what he could of American methods, and he later spent some time as a student with R. F. Holtermann. He was above the average in intelligence, as shown by his article on page 1257, Oct. 15, 1908, written, if we are not mistaken, when he had had only about a year's study of English. It was his intention to familiarize himself thoroughly with our methods, and then take the new ways back to his own country.

His death marks the end of what would surely have been a most brilliant career. It is the old, old story of an ambitious man so worried and hindered by a diseased body that the clear vision of life and

its possibilities was dimmed and distorted. Our sympathy is extended to his family and friends in Finland.—Ed.]

Dear Mr. Root:—I find it my sad duty to inform you that my brother Paul has voluntarily taken leave of life. He belonged to that class of men to whom life is especially a burden. High ideals and large plans, in connection with a sensibility which shrank from opposition, yielded to his inner conflicts. His was a retiring nature that prompted him to bear difficulties alone. He had resolved to devote himself to beekeeping in this country, and to further it with all his powers. His time was short; still he had, thanks to an ardent enthusiasm manifested to all who had deal with him, many friends and assistants in modern beekeeping, a knowledge of which he acquired in America. Of the great future for beekeeping in Finland he was, up to the very last, fully convinced. His bodily power was broken by a series of complicated inner troubles, and he leaped from the deck of a ship in the open sea on the night of November 2.

The late Paul Mickwitz, former student from Finland, of American methods in beekeeping.

He was much encouraged to see in GLEANINGS for Oct. 15, 1908, his contribution, with comments, in regard to moving bees on a boat with Mr. Holtermann. I can assure you that your journal has but few readers as much interested in it as was my brother. He read especially, in connection with his agricultural studies, much about apiculture. In one of the note-books which he left he had laid a plan for a yearly review of the most striking paragraphs, taken from the most prominent writers of all lands, and which he designed to publish in several languages, in order to further a union of the beekeepers of all lands. But he was not permitted to carry out this project.

His fifty stands of Carniolan bees in Langstroth hives have been taken over by myself; and I will do my best to carry on the work he began. I enclose a picture of Paul, so that you can use it in your journal if you so desire.

Alberga, Finland, Dec. 14.

THE JUNGE-PIERCE HIVE-VENTILATOR AND NON-SWARMER

BY EDMUND W. PEIRCE

Wanted—a solution of the swarming problem—a problem that hitherto has baffled solution except by time-consuming manipulation or the use of complicated, cumbersome, expensive devices. Even these expedients, in the hands of an average professional apiarists, have been productive of very indifferent results. Indeed it may safely be affirmed that neither manipulation nor machinery can of itself ever prove entirely effective. The most that can be hoped for, when the complexity of this problem is considered, is the perfection of a simple and inexpensive appliance that with minimum manipulation will, in a majority of cases, prevent swarming; and, when it does not actually prevent, will at least measurably control or retard it. This I believe has been accomplished.

A few years ago there appeared in GLEANINGS a description by Mr. Walter S. Pouder of a non-swarmers invented by Mr.

H. Junge, of Cumberland, Indiana, which had been used by him with considerable success, and on which he had obtained a patent. It consisted essentially of a deep super or shallow hive-body fitted with slats or fences suitably spaced, and with removable cleats for ventilation, designed to be placed on the hive between the bottom-board and the brood-chamber.

It is common knowledge among bee-men that room and ventilation are two most important factors in the prevention of swarming. How to afford these essentials without the incidental disadvantages of surplus comb-building, propolization, or drafts through the hive, has been the subject of much thought and experiment. Mr. Junge and I, each working independently and without the knowledge of the other, arrived at practically the same solution of the problem. A comparison of conclusions and modification and adjustment of ideas has resulted in what is known as the Junge-Pierce hive-ventilator and non-swarmers.

The illustrations will make clear the principal details of its construction. A deep super is fitted with a series of fences so spaced as to insure maximum ventilation to the exclusion of comb-building. From each side of the super a section is cut out, and the opening fitted with a door hinged at the top, and opening to various widths determined by turnbuckles at its ends. This opening is covered with screen wire tacked on the inside. The meshes, three to the inch, are large enough to afford free venti-

lation, and easy egress and ingress to the bees, yet small enough to exclude robbers, spiders, and moths. A removable cleat in the end of the super affords additional ventilation when desired.

The non-swarmers is left on the hive all the year round, and colonies so equipped seem to winter better than those without the appliance. It is understood, of course, that in cold weather the contracted entrance

is used, and the ventilators closed down tight. During the working season, or when the weather is very warm, the larger entrance is given and the ventilators opened wide. The ventilation is under perfect control, and can be adjusted to conform to varying weather conditions. It is very essential that abundant super room be given to prevent the crowded condition so conducive to swarming.

The principles embodied in this invention will be readily understood. The construction is such that there is free circulation of air under the frames, but absolutely no draft through the brood-nest. Surplus heat is carried off without danger of chilling the brood, and the bees are saved the greater part of the labor of fanning. Thus workers that otherwise would be so employed are rendered available for service in the fields or within the hive, to the obvious profit of the beekeeper. In order to enter or leave the hive, the bees must traverse at least a part of the non-swarmers. They are thus given the impression that they have abundant room, though in fact they are cheated out of it, so far as storage is concerned, the internal arrangement being such that the space is not available for comb-building. Furthermore, a convenient clustering place is afforded the nurse-bees, and this, by relieving the internal congestion,

tends to prevent the development of the swarming impulse.

As has been indicated, it is not claimed that this invention will at all times and under all conditions prevent swarming. It has been pretty clearly demonstrated, however, that, with intelligent use, it will prevent swarming in a great majority of cases; and when it does not actually prevent it, it will so retard it that days and possibly weeks of honey-storing will intervene. Moreover, swarms, when they do issue under these conditions, are apt to be unusually large and valuable.

While making no extraordinary claims for their simple device, the inventors feel that therein are involved principles that are vital factors in a satisfactory solution of this hitherto unsolved problem.

Zanesville, Ohio.

USING A STRAIN OF BEES ADAPTED TO ONE'S SYSTEM OF MANAGEMENT

BY E. S. MILES

The amount of prevention desired must depend largely on one's location and the time of the main crop, as well as on one's knowledge and ability to make increase by other methods.

Where the main crop comes early and the flow is short, and one must get the most possible surplus from it, it has been my experience that the colonies that do not swarm at all, and that have no desire to, either as a result of manipulation or because of breeding, are the most profitable ones.

My main crop is basswood, which lasts from three days to two weeks, sometimes helped out a little with clover, catnip, and buckbrush.

It does not come so early but that with a favorable spring a colony *might* swarm; and with proper feeding, both the swarm and the parent colony be in condition for the flow. But our Iowa springs are so variable and uncertain that I find it safer to count on getting only enough from the best

colonies to bring up the weaklings so that, if I can reach the flow with all the colonies of that winter in good condition, I feel satisfied. Then, as mentioned before, I expect more honey if they do not swarm during our short flow.

I feel sure there are several practices the beekeeper can follow that tend to increase the number of colonies, and that may prevent swarming. I will try to give them in the order of their importance as they appear to me:

1. Breed all queens from colonies that have shown the least inclination to swarm, using queenless and broodless bees to build the cells, or at least to start them.

2. See that no colony is crowded for room up to the middle of the flow at least.

3. See that each colony is blocked from the bottom-board from $\frac{3}{4}$ to one inch in front, just before weather hot enough to crowd them out begins.

4. See that every colony is protected from the direct rays of the sun from about 10 A. M. till about 4 P. M.

5. See that every colony has comb built in readiness for the first surplus that comes.

It will not be necessary to dwell much on any of these points except the first.

The question of the *strain of bees*, as related to one's system of management has not, in my opinion, yet had the consideration its importance deserves. It is well known, and acknowledged by a great many practical honey-producers that almost all manipulation has to be varied to suit the characteristics of different colonies. Now, if we want a certain plan of manipulation to apply to all colonies we must have less variation in our colonies; and in order to handle the most colonies possible with a given amount of labor we *must* apply one manipulation or plan of treatment to all—manipulation here being considered only in its relation to swarming. If there were no variation in bees in regard to swarming, a manipulation that would give us the desired result with one colony would with all.

It might be said that a manipulation such as "shook swarming" or any process that cripples a colony or keeps it weak enough to prevent swarming proves that that manipulation answers the purpose.

But for the locality I have in mind it is not the purpose to have a part of a colony. We want a full colony, all the bees one queen will produce, and we want them to stay in one hive clear through the flow. It may now be asked how large a colony we may expect to have in this way, considering the nature of the bees.

It has been my observation that a colony is most likely to swarm about the time, or very soon after, the bees have reached their maximum breeding capacity, every thing else being favorable. If this is right, a colony or strain that reached the maximum breeding early in the season would be that much sooner past the swarming period; and if this earlier part of the season were less favorable for swarming, owing to certain weather conditions, then there would be less tendency to swarm on the part of this kind of strain.

Then, again, many think that an over-supply of young bees in proportion to the brood and honey to be cared for is likely to be a prolific source of swarming. If a strain reaches its maximum breeding early, say about the time of fruit bloom, then the dearth after fruit bloom discourages swarming, and so cuts down breeding that, when the main flow begins, there are plenty of old bees or fielders, yet no surplus of young, nor can there be for a month. Such a colony is just right for gathering and storing the most surplus, and is *not* in a condition to swarm. Is it not evident that, if one breeds a strain best suited to his "locality," other "manipulations" will be more effective, and the variation in all colonies be less marked? Of course, one should always take note of the variations of the seasons. If, at fruit bloom, conditions should be very favorable, increase might have to be made in order to prevent swarming. But the gain would come from the labor saved at the time of the main crop, and this saving could be applied in "keeping more bees" as well as in more surplus per hive.

Dunlap, Iowa.

DOOLITTLE METHOD OF SWARM CONTROL NOT A SUCCESS IN IDAHO

BY E. F. ATWATER

As soon as the essential features of the Doolittle method of swarm control in the production of comb honey had been published the writer gave the method a test in several yards, and that test has been repeated each season, although on a smaller number of colonies. We have no hesitation in saying that, if the method would give the results in this locality that it gives Mr. Doolittle in his own location, then it would be, in many ways, the ideal plan for out-yards and comb-honey production. But we find that far too many of the colonies shaken on the combs which had been above the excluder will swarm again in less than three weeks, resulting in poor super work,

and adding to the labor of swarm control. Only rarely does a colony treated by the Doolittle method prove superior to the average; and never, so far as the writer can remember, has such a colony proved the best in any yard. We even procured a breeding queen from Mr. Doolittle and requeened a number of colonies with her daughters, especially to test his method of swarm control; but even then the Doolittle system, with bees from Doolittle queens, has not been successful. The only favorable report that the writer has heard is from Mr. H. M. Weidner, of Payette, Idaho. We regret that the method has not fulfilled its promise, for we had hoped much from it.

We find that any system (natural or forced) of hiving swarms on combs does not give best results for the production of comb honey—owing, apparently, to the fact that the swarm is not satisfied. When we hive on foundation more energy is displayed, and a far smaller number of colonies will again attempt to swarm. We have tested some modifications of the Doolittle method—for instance, tubing the bees from the old brood-combs, as they hatch, into the new colony, desirable for a week at least to reinforce the colony with more bees.

Another difficulty is that in most parts of the arid West there is a marked reluctance on the part of the bees to carry up, into the combs above the excluder, any excess of honey in the brood-nest, until too late to give the queen sufficient room to lay. Even the Carniolans, least of all inclined to crowd the brood-nest, show this tendency to a marked degree if the excluder is used; while without the excluder there is no disposition to crowd out the queen in May or early June, before time for shaking. The Doolittle method does not give brood-room sufficient to prevent all colonies from getting the desire to swarm before the honey-flow unless an extra story of combs be given to the best colonies in May, so that the queen has access to the combs in more than one hive-body.

We have tried giving the queen the liberty of two hives of comb instead of confining her to one. Then when the proper time arrives we sort out the combs with little or no brood, and shake on them, which is more work, but which gives stronger swarms on the average, and with less danger of swarming before the flow. As before, however, too many seem not to realize that they have been swarmed, and must try it again. There is no question that, in nine cases out of ten, where we have used the Doolittle method, we could have secured

more profitable results if the bees had been shaken on foundation, and the combs above the excluder had been extracted. We therefore have no further use for the Doolittle method unless with a few colonies as an illustration to our students, and we await with interest the publication of a method which does not involve much uncertainty and the expenditure of a very large amount of labor.

Many of the former advocates of shaken swarming are now doing little or no shaking except of diseased colonies. They merely destroy cells, etc.; then if a colony persists in swarming they kill the queen, cut out cells, and, about nine days later, give them or leave them one cell. To tell the truth, there is as yet no method publicly known for controlling swarming in out-yards run for comb honey that is really satisfactory and adapted to a large business.

We have a plan which we use very largely, which gives good results; but it is quite laborious when several yards must be handled. Upon the opening of the flow, which is the signal for most of the swarming here, we shake into a new hive, with full sheets of wired foundation in the frames, three-fourths of the bees from two colonies. This plan gives powerful colonies, good for some fine work, and secures comb honey if there is a flow. But for the past few seasons, with large yards of 200 upward, too many such swarms will come out again once or twice, before settling down to work; and if a comb of brood is given when shaking, the bees will start unnumbered queen-cells upon it, and refuse to stay until the brood is removed, as described by L. Stachelhausen several years ago. It is possible that this disinclination to stay hived may be due to the use of full sheets of foundation, as this has been spoken of by several writers; but the condition was not so apparent when our yards were smaller. If the dividing of the cluster by the full sheets of foundation be the reason for the discontent, we can obviate it by giving an empty body below the swarm for two or three days. We will test the matter thoroughly this coming season.

If increase is desired we may give a queen or a cell to the shaken colony (one of the old brood-nest), or pile several such bodies of comb above the excluder on some weak colony, and use for increase when the brood is sealed, or leave them to be filled with honey for extracting. The writer has several times had hundreds of such hives of sealed brood piled above excluders, awaiting the arrival of queens from the South,

only to lose the opportunity to get a large increase by the failure of the queens to arrive until too late.

Here, if we can get a layer into a hive of brood or on a few frames of brood, in early June, we have a colony as good as the best for our second flow. If, on the other hand, we must wait and allow them to mate a queen, then they will be so much weaker when the second flow comes than they would have been if they had had a layer at the proper time, that they will often store little or no surplus from that flow.

Where are the queen-breeders who will give a bond to send queens at the time they have agreed to do so?

Meridian, Idaho.

MAKING INCREASE BY SHAKING BEES FROM STRONG COLONIES INTO SWARM BOXES

BY I. B. ELLIS

Assuming, first, that there are at least two bee-yards two or more miles apart, and that you want to double your number of colonies, you should first go to a tinner and have a funnel made about eighteen inches across the top, with a two-inch hole at the bottom. Next make about twenty swarm-boxes. I make mine by taking new red-wood shakes and cutting them in two in the middle for the sides; and for the ends I use blocks $\frac{7}{8}$ thick by 6 inches square, nailing all together. Cutting out nearly all of one side, I tack on a screen, and bore a two-inch hole in one end of the swarm-box to hold the funnel.

You are now ready to go to your apiaries and make the increase. It is necessary to build up the yards early in the spring by artificial feeding until the yield of honey begins from the early flowers. At yard No. 1, first go to a strong colony and find the queen; then set aside the comb containing her. Have the helper hold the funnel in the swarm-box while you shake two combs with adhering bees down into the funnel. Give them a quick shake, and the bees will go rattling down into the swarm-box. Shut the hive and go to the next strong colony, and take out two combs of bees as before, being careful not to get the queen. Shake the bees into the funnel as before. When visiting the next colony take out only one frame of bees (it does not need to be quite as strong), and shake them into the funnel. I like to take out five frames of bees and confine them in a swarm-box, as it makes a nice little colony. Now take out the funnel and slip the slide. Proceed in the same way until the twenty swarm-boxes are filled.

If you are quick and have good luck in finding queens, and work fast, you should have the twenty boxes of bees in five or six hours, or about 3 P. M.

Now take a laying queen and drop her right down in among the bees, one for every swarm-box. Give the queen-cage a little shake, and out she goes. It is better to buy your queens if you can get them; but if not, the queens already raised which you have on hand may be used.

Going to yard No. 2 we arrive by 4 P. M., taking the boxes of bees. Put them in the shade, and then arrange twenty hives. Set them where you want them to remain, and go to the supers of the old colonies, and take out four frames of honey and comb, selecting combs about half full of honey, and one sheet of foundation, putting the sheet of foundation next to the outside comb. When the hives are all set, and ready for the swarms, slip the slides of the swarm-boxes, and shake the bees in front of the hives (one box for each hive). It is just about sundown by the time you are busy shaking the bees out of the boxes in front of the hives and seeing that the bees go in.

The next morning go through the same process at yard No. 2 that you did at No. 1, taking the funnel and swarming-boxes and shaking the bees in till the twenty boxes are full. Drop in twenty laying queens, and return to yard No. 1, and fix the hives in the positions in which they are to remain. Take four sheets of honey, partly full, from the super of the old colony, and one sheet of foundation for each hive, putting the sheet of foundation next to the outside comb.

Now it is getting late, and we run the twenty swarms into our twenty hives the same as we did the evening before. We keep this up until we get all the supers of honey used up, or as much increase as we want.

The old colonies will stand a draw of a couple of sheets of bees again in seven or eight days, and possibly more. It all depends on the condition of the weather, and how fast the brood is hatching. One has to judge by the looks of things. Draw from the old colonies for the purpose of swarm prevention till the honey flow is on in earnest, and supply foundation for both the *old colonies* and the *new swarms*.

The third week the swarms are storing more honey than the old colonies that we drew from. Last year I started with 88 colonies in the sage district of California, having also 200 supers of combs from which the bees died the year before. I in-

creased to 210 colonies, and took 20,750 pounds of extracted honey.

St. David, Ariz.

PROPER PACKING AND GRADING

BY LOUIS SCHOLL

There is at present no other matter of so much importance to the Texas beekeeper, and the entire South, for that matter. There exist, at the present time, no definite rules that govern the packing and weight of the various packages of the honey of the South, as regards what might be termed a standard by which to go absolutely, both as to the manner in which the various sizes of cans and pails used shall be filled, and as to the weight of honey they should hold.

There seems to be quite a diversity of opinion among even our leading beekeepers; and as long as this continues we may expect trouble from time to time with the buyers of our products. While some claim we ought to let the weight include container with the contents in the selling weight, others furnish a full net-weight package. The latter seems far the better way, and one that can be easily arranged, and at the same time will be more in conformity with the present regulations of the pure-food laws. But if some of us are doing this, all should do likewise; for it makes quite a difference with a large crop whether we are *compelled* to furnish full net weight of honey as against those who include the containers as part of the weight.

Another most important item, and one that needs a lot of "clubbing," is that of packing dark off-grade honey in with fine white comb honey. Often such stuff is so far "off" that it is unfit to eat, and hence the practice should not be permitted to go on.

The matter of the proper amount of comb honey in proportion to extracted honey in packing "bulk comb honey" needs some adjustment before our next packing season rolls around. While some beekeepers, to be honest, put a large amount of comb honey in the cans, and less extracted, others vary these amounts to a great extent, and just as honestly. The trouble is, we have no real standard to go by, and such should be provided.

We have a great deal of trouble also when it comes to the prices of honey. There are quite a number of beekeepers who believe in keeping the price up in proportion to the supply and demand, and in relation to other commodity prices, so far as practicable. But this often—yea, very often indeed—works against them in the prompt dispos-

al of their products. This is because there is such a difference in the price at which various beekeepers sell their honey that the lower prices prevent others selling their honey.

A better organization of the beekeepers, or even a simple "getting together" and discussing these various questions, would bring about an improvement over the present-day situation.

New Braunfels, Texas.

A FURTHER NOTE OF WARNING AGAINST SPRAYING WHILE IN BLOOM

BY PROF. N. E. SHAW,
State Entomologist of Ohio.

The time of year is now at hand when the spraying campaign is started against the many pests affecting our fruit-trees. A word of caution should be given for the benefit of those who disregard the advice of authorities and spray their trees while in full bloom. There is nothing to gain by the application of spray at this time, but, on the other hand, positive injury is sure to result to the vital parts of the flower, and likewise to bees and other insects which are so necessary to the proper development of the fruit.

For a time the correctness of reports from correspondents (that many orchardists sprayed their trees while they were in full bloom) was doubted. During the past year reports of this kind were investigated by inspectors, and it was found that the practice was being followed to a considerable extent. A few of the offenders, strange to say, are some of our largest fruit-growers whose spraying equipment is not sufficient for their orchard acreage; and in order to spray all of their trees before the closing of the blossom end of the apple, they commence operations while the trees are in full bloom.

Another class of offenders is composed of those who do commercial spraying for small orchardists. Their object, of course, is to extend their work over as long a period as possible, and many of them spray right through the blooming period, regardless of the condition of the blossoms. Their employers are usually ignorant of the harm done by the practice, and make no stipulation as to the time during which the work must be performed.

This Department will make every effort possible to discourage this harmful practice, and asks the co-operation of beekeepers in reporting all instances of this kind that come under their observation.

Ohio Department of Agriculture.

Heads of Grain from Different Fields

A Bottom-board that Does Away with Sulking Bees

I can not remember now whether it was Dr. Miller or Mr. Doolittle who advocated putting blocks under the hive in summer to give bottom ventilation. I am quite sure that it is Dr. Miller who uses the bottom-board with the deep space under the frames, with the idea of giving more ventilation than can be secured by means of the ordinary bottom-board. That two such successful beekeepers find it necessary to have more ventilation is pretty sure evidence that there is something lacking in the standard make of bottom-boards. In my own experience as a beekeeper I have found that, when using the regular make of bottom-boards, it is almost impossible to crowd the bees sufficiently to get results in comb honey without their sulking and hanging out on the front of the hive. Abundant bottom ventilation has always been in accordance with my idea, but I do not like the plan of the blocks very well for more reasons than one. The chief reason was that, when the hive was set on these blocks, it gave the bees an entrance from every side of the hive, and I can't say that I enjoy opening a hive when the bees in about every third hive are going to pile out and sting a row all around my ankles.

This bottom-board is made just like the ordinary reversible bottom-board, except that, instead of the deep entrance being only $\frac{3}{8}$ or one inch deep, mine is two inches deep. Then an opening is made on each side and at the back, one inch deep, extending each way to within three inches of the corner. This opening is covered with wire cloth, which compels the bees to go to the regular entrance, and keeps them away from my feet and legs. At the same time they have a free ventilation from all sides; and after using this bottom two years (last year on fifty colonies) I have yet to see a single colony hanging out over one of them. This certainly must have a decided influence on the swarming problem.

These bottoms are ideal for moving bees, for all you have to do is nail up the entrance tight, and the wire-cloth-covered holes will give abundant ventilation. Then, again, when wintering in the cellar the bottoms can be left on, and still there will be almost as free a ventilation as if there were no bottom at all. When the weather is too cool for the wide entrance the reverse side is just the same as the shallow entrance on the regular bottom-boards. The drawings will illustrate the construction.

Barryton, Mich.

LEON C. WHEELER.

A Modification of the Alexander Method of Increase

Will you be kind enough to state objections to the following modified plan of Alexander for increase and prevention of swarming? Select a strong colony with a quantity of brood in all stages of development, before the clover flow starts, or, preferably, about one month before the clover flow. Look through the colony carefully, and remove every queen-cell. Have a new hive ready with frames of foundation, but with one place left for a frame of brood. Place the new hive on a stand near the first, and then remove a nice frame of brood from the old

hive and place it in the center of the new hive. Find the queen, and introduce her into the new hive (if possible, select the frame on which the queen is found). Now remove the old hive to a new stand some distance away, and place the new hive on the old stand. A queen may now be introduced into the old hive; or would it be better to leave one queen-cell if one is present? Would the delay of 16 days, caused by raising a queen, be a serious handicap to the colony for handling the honeyflow?

Decatur, Ga.

H. B. ARBUCKLE.

[As many of our readers have, perhaps, forgotten the original Alexander plan, we are giving it here.—ED.]

When your colonies are nearly full enough to swarm naturally, and you wish to divide them so as to make two from one, go to the colony you wish to divide; lift it from its stand and put in its place a hive containing frames of comb or foundation, the same as you would put the swarm in, providing it had just swarmed. Now remove the center comb from this new hive, and put in its place a frame of brood from the old hive, and be sure to find the queen and put her on this frame of brood in the new hive; also look it over very carefully to see that it contains no eggs nor larvæ in any queen-cells. If it does, destroy them. Now put a queen-excluding honey-board on top of this new hive that contains the queen and frame of brood with their empty combs, then set the full queenless colony over the excluder; next put in the empty comb or frame of foundation taken from the new hive, and close the upper hive except the entrance they have through the excluder into the hive below. Leave them in this way about five days, then look over the combs carefully, and destroy any larvæ you may find in the queen-cells unless they are of a good strain of bees that you care to breed from, for they frequently start the rearing of queens above the excluder very soon after their queen was placed below the excluder. If so, you had better separate them at once; but if they have not started any queen-cells above, then leave them together ten or eleven days, during which time the queen will get a fine lot of brood started in the lower hive, and every egg and particle of larva that was in the old hive on top will have matured, so it will be capped over and saved; then separate them, putting the old hive on a new stand. It will then be full of young bees mostly, and capped brood, and in about twenty-four hours they will accept a ripe cell, a virgin, or laying queen, as they will then realize that they are hopelessly queenless. I would advise you to give them a laying queen, as I never like to keep my full colonies for even a day longer without a laying queen than I can help.

In this way you secure two strong colonies from one, without losing a particle of brood or checking the laying of this queen; and with me it almost wholly prevents swarming. This is the way we have made our increase for several years, and we like it much better than any other method we ever tried. In doing so we keep all our colonies strong during the whole summer, and it is the strong colonies that count in giving us our surplus.

The mere fact of having a large number of colonies does not amount to much unless they are strong in bees and are well cared for at all times. This is a fact that many have sadly overlooked; and when the season comes to a close, giving them a small surplus, they feel disappointed and lay the fault on many things that have had but little to do with their failure.

[Your modification of the Alexander method of increase is not as good as the original Alexander plan, for this reason: You remove the old hive to the new stand at the time you make the division of the colony, while Mr. Alexander puts the old hive

over the new one with perforated zinc between. The object of this is to save the young brood that is unsealed. In five days, as Mr. Alexander directs, all the brood will have been sealed up, and quite a number of young bees will have hatched out. At that time the upper story with its young bees with nothing but sealed brood can be put on another stand much more safely than it can be done at the very beginning when there is unsealed brood and less of young bees.—ED.]

Feeding During a Time of Making Increase

Dr. C. C. Miller:—Please let me know whether the method of applying the Alexander feeder at the time of making increase, as per your article in *GLEANINGS*, May 1, 1912, p. 266, and feeding a pint of syrup every night for 14 nights, so that the increase will rush things for the basswood flow and buckwheat would apply to conditions similar to those given on p. 279, May 1, 1912. Do you approve of the use of the Alexander feed in cases of this kind, as the cost of syrup will be only about 30 cts. per colony? Will it pay to spend this much in the above cases?

Canastota, N. Y.

WM. P. FRITZ.

If I should feed in the way you suggest, I don't believe it would make enough difference to pay for the trouble, if, indeed, it would make any difference at all; for at the time the increase would be made the bees would be gathering enough and more than enough to supply the brood, and extra feeding would not increase the laying of the queen. There are, however, a few localities where it might pay well. There may be particular seasons in almost any locality where feeding would pay big. In the first half of June I expect my bees to be doing a land-office business if the crop is to amount to anything that year; and it would be foolish for me to feed at that time. But one year there was a dearth in June, and before I realized the situation the bees were carrying out the white skins of larvae from which they had sucked the juices. I could well have afforded a dollar a pound for sugar to feed at that time. Now, suppose a locality where the weather is favorable during the time you would want increase, but there was nothing from which stores could be gathered, while a heavy flow might occur later on. In that case it would pay well to feed, so as not to have any break in brood-rearing.

The gist of the whole matter is this: If bees are already having all the brood they can cover, feeding will not increase it. If they are already gathering abundance of stores for brood-rearing, feeding will not hasten the building-up; but if bees are not gathering enough to keep up brood-rearing, then feeding may pay well.

Marengo, Ill.

C. C. MILLER.

Spring Uniting

In May of last year my bees were near the point of starvation; and as I did not see any prospect ahead for honey I united a part of my 55 colonies so that there were only 38. I intended to keep on uniting until I had only 25, as I did not want to have to feed so many; but about May 15 the colonies seemed to be so strong that I thought I would wait a few days and then unite more of them if I desired. About the 20th they began bringing in some honey, and they kept at work. Up to that time I had had three or four swarms. That is all I had that season. I stacked up supers, three or four to each colony, and when the season was over I found I had sold \$121 worth of comb honey near home, and I had besides 22 hive-bodies full, and many unfinished sections.

I will describe my way of uniting. If A and B are to be united, A being the stronger of the two, I lift A from its stand; set B in place of it; then

remove the cover from B, blow in a little smoke, and finally I smoke a little at the entrance of A. Then I loosen the bottom-board of A and set it on top of B. I do this when the bees are flying freely. If there is any choice in the queens, I kill the undesirable one; but if not, I let them alone. Sometimes the two remain together; but I have never known more than two instances when the queens lived together all winter.

Late in the fall the bees will usually be in the upper hive; and if the colony is not too strong I separate the two hives and give the best set of combs to the colony.

Fremont, Mo.

MRS. ALMEDA ELLIS.

Transferring without Drumming Bees

I notice in *GLEANINGS* for March 1, pages 154 and 155, illustrations of transferring which seem to me to be altogether out of date; for, in the first place, drumming out bees is quite an unnecessary waste of time. The quickest and easiest way of transferring is to turn the hive upside down, fasten a box in a slanting position over the bottom, of course having used your smoker first. Then with a hammer and hatchet split off the side that has fewest combs attached. Smoke back the bees; cut out the first comb; put the dry comb into one hive, and comb with honey into another; smoke the bees off the second comb, and repeat, cutting out any comb containing brood, and so on. By the time the last comb is out the bees will be in the top box, and the queen either found in cutting out combs or remaining in the old gum.

Having transferred hundreds of gums in this way, I have found it to be the quickest and easiest way. Before I fasten on the small box I note particularly how the combs are fastened to the gum, and choose the side having the fewer fastened to it; for the side to be opened, there would not, in nine cases out of ten, be a quarter of the flying and loose bees as there are shown in the illustration. Turned upside down, the combs are often found attached to the sides of the hives.

I don't say any thing about the crossway sticks, as they are very easily gotten rid of.

Allenville, Ala., March 10.

H. F. HART.

[An expert can transfer from a box hive quicker by the method described by our correspondent than by the process of first drumming the bees out of the hive. The average beginner, or, rather, the person who tries transferring from a box hive the first time, will succeed better—that is, he will have less fear of stings if he drums the bees out first. Years ago, when the writer was learning his A B C's he found it more practicable to transfer as described by Mr. Hart; but at that time we had bought some 25 or 30 box hives, and we transferred them all in two days.—ED.]

Giving Room Beneath Instead of on Top

When the bees need room in the spring, having been wintered in two 5%-inch bodies, would it not be a good plan to put the third one under the other two and allow the top one to become an extracting-super, when it could be thoroughly cleaned, as well as the frames, of all propolis, and repaired if necessary? In this way one half of the hive would be cleaned every year. The bees, I believe, would be inclined to store the honey above, and allow the brood-nest to be extended downward; and, furthermore, the loss of heat would not be so great with the empty body below as it would be if placed above the brood.

H. C. DUNN.

East McKeessport, Pa., March 19.

[The proposed plan of putting the third shallow brood-chamber under the other two is an excellent idea, especially at the beginning of the season. It is

better to give room at certain seasons of the year in this way than to put it at the top. The only objection to it is that there will be considerable brood reared in the top story; and, later on in the season, you would have to reverse the process by putting the empties on top and the perforated zinc between the brood-nest proper, whether there would be one brood section or two, and the extracting-super above.—ED.]

Apigrams from the Southeast; Stop! Read! Remember!

Give all colonies and every comb a thorough examination this spring.

Notice (and make a note of) the condition of every brood-nest, and make a second examination with equal attention, in two or three weeks, so that every queen whose work is inferior may be replaced, for a poor queen means a profitless colony.

Remove all combs that contain more than a dozen or so drone-cells, and melt up for wax; for many unnecessary drones are a heavy tax on the profits.

Remove all combs that have dry mold in the wax. If you don't, the bees will, and they will put drone comb in its place. If you remove it first, you profit in two ways—you save it for wax and you save their labor, which labor consumes honey and bee life.

Permanent enthusiasm is maintained mainly by profits, and profits are secured mainly by hard work and head work suitably mixed; so if you wish to retain the joy of enthusiasm in your beekeeping, get busy on the mixture.

Get two kinds of wax-extractors in your apiary, if you have not already done so—a sun wax-extractor for scraps, and a wax-press of some good kind; for in warm regions it pays much better to melt all defective comb than to patch it, for wax is “quick money.”

When you walk through your apiary, have seeing eyes and hearing ears; for by entrance appearances may the inward condition of your colonies be known, and much hard labor be saved thereby.

It is not the bees that buzz the loudest that make the most honey.

Good seasons come both singly and in flocks; ditto with poor ones; so if you get a succession of good crops don't felicitate yourself on your cleverness. The lean flock may be even now at your door, to tax your prudence and endurance to the limit.

Rejoice in the bountiful years, and let the bees teach you to lay by for the poor years, when you shall need to step softly over the graves of “blasted hopes.”

Mt. Dora, Fla.

G. J. V.

The Capriciousness of Swarms

Hiving swarms was a difficult matter for us last summer. The bees seemed undecided as to what they wanted to do, and would come out, settle, and then either move to another place or do some other queer stunt. Only one swarm, the first, was reasonable in its actions. It settled on a thornbush. I bent the bush down, gave it a blow, and the bees crawled into their new hive as calmly as the animals walked into Noah's ark.

The next swarm settled on the top of a tall young maple. I climbed up a ladder and cut off the limb while the hired men caught it on a forked pole and let it down in front of the new hive. The bees went in. But after that our troubles began.

A fine big swarm came off when I was away from home. It settled all right, and then the hired men sat down to dinner, intending to hive it after dinner. But meanwhile it soared away through the sky, and was lost to sight, though to memory dear.

The next time a swarm came off I was at home; but I might as well have been away. It alighted on

a low walnut; but while I was putting the hive in position, there was a rumble of thunder. The bees became frightened, and fled back to their hive. Then if I had only had a queen-trap I could at least have saved the bees. They issued the next day with their queen, and took refuge in the tall timber, and were lost.

I keep bees for the purpose of pollinating my orchards, and to them, in part, I owe my immense crop of 8000 bushels of red juicy apples which I gathered last year.

New Wilmington, Pa.

J. C. M. JOHNSTON.

Dropping a Swarm from a Tree into a Hive

I had a swarm cluster in the top of a large elm-tree. As I could not reach the limb I climbed the tree, and, with a cutter on the end of a long pole, cut off the branch and let it fall to the ground, bees and all, having placed the hive at about the place where I thought the bees would fall. The limb struck the ground within three feet of the hive, and the bees all ran in.

Long Neck Sta., L. I.

E. GRISWOLD.

[This plan you mention would, undoubtedly, be a good expedient in the emergency you mention; but ordinarily, if it is possible to reach the limb it is a little safer to let it down with a light rope after it is cut off. If you missed your calculation as to where the limb would strike the ground so that you did not get the hive near enough; or if the limb struck any thing else on the way to the ground the bees would probably get away from you.—ED.]

An Easy Way to Fill Combs

Last spring I had to feed my bees, and desired to do so by giving them sugar-water in combs. I filled my fountain-syringe bag, and the thin stream directed at the cells caused hardly any drip. The air was driven from the cells, and had plenty of room to escape. It was far beyond the dipper method or the immersion way.

Iowa.

J. GAUS.

[The plan described is perfectly feasible. While we have not tried it, we know that one can secure filled combs in the manner described, with a good deal less spatter and daub.—ED.]

Cells Filled with Pollen in Aspinwall Hive

I have tried two Aspinwall hives this season; but with my management they were not especially successful. There was no swarming, but I had some bulged sections, a few thin ones, and nearly a third of the sections next to the brood-chamber contained one or more cells of pollen. The queens also went above, and a number of sections contained brood. In our regular hives, pollen is never found, and brood is rare in comb-honey supers. These hives may work better under other conditions and management. I shall continue the trial, and hope for better results.

Fair Oaks, Cal.

E. L. SECHRIST.

416 Pounds from a 24-Year-old Colony

Our last exploit was to get 416 lbs. of honey from the only colony of bees we had, and then have the colony live 24 years in the same hive. The hive actually rotted away from the bees.

Galva, Ill., March 13.

LLOYD Z. JONES.

\$17 Worth of Comb Honey from One Colony

With reference to keeping down increase and running for comb honey, I would say that I have one colony that produced \$17.20 worth of section honey, and cast one swarm.

Sunbury, Pa.

Our Homes

A. I. ROOT

Behold the fowls of the air; for they sow not, neither do they reap, nor gather into barns; yet your heavenly Father feedeth them. Are ye not much better than they? Which of you by taking thought can add one cubit unto his stature? And why take ye thought for raiment? Consider the lilies of the field, how they grow: they toil not, neither do they spin; and yet I say unto you that even Solomon in all his glory was not arrayed like one of these. Wherefore, if God so clothe the grass of the field, which to-day is, and to-morrow is cast into the oven, shall he not much more clothe you, O ye of little faith? Therefore take no thought saying, What shall we eat? or, What shall we drink? or, Wherewithal shall we be clothed? For after all these things do the Gentiles seek; for your heavenly Father knoweth that ye have need of all these things.—MATTHEW 6:26-32.

Mrs. Root and I have now been here in our Florida home close on to six months. Neither of us has had a sick day, and I myself have scarcely had a pain or ache. Neither of us has had any thing worth mentioning in the way of a cold, and nothing at all like grip that has again been so prevalent throughout the cold North. Other winters we have had more or less of cold and grip, and similar troubles along that line. Now, then, can I give any of you any suggestions in the way of *getting* well and *keeping* well—especially in the winter time or in cold damp weather? T. B. Terry has lately been having a good deal to say in regard to having open airy rooms, and getting oneself *hardened* or acclimated to cool weather without being excessively bundled up. Mrs. Root has also been for years past urging that I should get rid of my fur cap and the unusual amount of clothing that I felt that I must wear in order to avoid "taking cold." She has over and over again urged that, if I would take proper care and precautions, I could get tough so that I could stand a little exposure without having neuralgia, rheumatic pains and aches, and things of that sort. Well, early in November I began getting rid of my fur cap, endeavoring to keep warm by vigorous exercise in the open air without so much clothing. In place of wearing an overcoat when it was cold, by Ernest's advice I got me a woolen sweater that could be easily thrown off or put on as circumstances or the weather seemed to demand; and right here I want to say that that woolen sweater has been one of the greatest helps and comforts of any thing I ever got hold of. Well, now, let us go back a little.

The first time I took off my coat and went to work in my shirtsleeves, even down here in Florida, the consequence was a stiff neck. Most of you know what that is with-

out my explaining. I began to say that I couldn't stand it—that I was too old, and that my circulation was too poor; but Mrs. Root urged that, if I would keep trying, pretty soon I would get toughened to it so I could get along without a coat or without a sweater. Well, the next day I tried taking off my coat again; but, as before, the consequence was a stiff neck, but I was obliged to admit that it wasn't quite as bad as the day before. The third day there was very little of it; and after that the stiff neck disappeared entirely. I went on with my experiments along that line, and not only discarded my coat, but after a time my vest, then put on lighter union underwear than I had been in the habit of using, and finally I went out and worked hour after hour with my coat and vest off and my sleeves rolled up, my underwear turned back, and not only my neck but my chest exposed to the sun and air and the weather. I also laid off my woolen stockings, and put on gradually some of the thinnest cotton; and of late, during February and March, I have been going barefooted through the middle of the day; and, to tell the truth, while I dictate this to the dictaphone I am sitting down here barefooted, bareheaded, with my collar turned back just as I have been describing. The fact that I could get along and be comfortable and happy with so little clothing has really given me a new lease of life. I enjoy my work and my meals, and I enjoy reading my books and papers after I have been out working in the ground or out with the ducks and the chickens. I firmly believe that we as a people have been wearing more heavy clothing, both men and women, than God intended we should. Aye, further, I am satisfied that many of us might live many years longer, and in more comfort, if we could only convince ourselves that it is possible to wear *less clothing*, and clothing that permits the air to circulate all over our bodies. I believe history tells us that in one of the islands in the seas they discovered a race of people that went entirely naked: but when these people were civilized and Christianized, and taught to wear clothing like other people, the race gradually lost in vitality, and threatened to become extinct unless they could be allowed to go back to their old ways and habits of being out in the open air with scarcely a rag of clothing to protect them or to look decent and civilized. Furthermore, it has lately been discovered that roop and a host

of other diseases that afflict chickens come about just because they are shut up too close and do not have enough air. "Killed with kindness" expresses it exactly. I am inclined to think that many human beings, the precious little babies included, *have* been killed with too much kindness and too much care to protect them from this beautiful, bright, invigorating outdoor air. In saying this, however, I do not want it to be understood that I mean to ignore the effects of draft or sudden exposure to weather without proper protection. I can't understand why it is myself; but I know this—that, if I sit down inside of the house with the doors and windows all open, there is danger of a draft that may give me a cold; whereas if I were to go right out in the open air, right in the very breeze that seemed to hurt me before, the wind causes little or no inconvenience. There is something peculiar about the draft of air that comes in and out through openings, such as doors and windows.

I read of a hunter who said that, while he was out camping in the woods, he was perfectly well—hadn't an ache or pain, no touch of rheumatism nor any thing of that sort. When he got back to civilization, and slept in the house, his old troubles all came back. Why is it?

Let me now go back to the matter of clothing. For years past—in fact, I can hardly remember the time when I didn't wear a starched shirt with white bosom and starched collar to match. I think that, while up in the "cabin in the woods," in Northern Michigan, I did for a time adopt what they called then a calico shirt. Late years it has been that starched front, so impervious to wear winter and summer—as long, in fact, as I can remember. During the past winter, however, I have ceased patronizing the laundry. Our oldest daughter paid us a visit, and she and Mrs. Root decided that it was too bad that I should go up town looking as I did, and they finally found some light summer shirts, so very thin that I scarcely knew I had any on at all, and which made me look a little more decent and like other people. And, besides, if I find this obstructing the air and breeze and sun too much I can unbutton it and throw it back without very much trouble. One of the most beautiful pieces of modern statuary I ever saw in my life—at least one that I have looked at and admired as much as or more than any other—is in our Medina cemetery. It pictures one of the old pioneer wood-choppers who cut down the great trees in Ohio, and established homes and colonies. This wood-chopper stands on a log, ax in one hand, with his hat off and

head thrown back, collar unbuttoned and turned back so that he exposes fully to view the muscles of his neck and chest. This athletic wood-chopper is in the full prime of life, and I should say from the looks of the picture that he is also enjoying such a life as God intended he should have out in the open woods, and taking the best exercise that every one of God's children should take to enjoy fully the gift of a human life to live. Before sitting down to my dictaphone I had been out in the lot with my colored man, Wesley, spading up the mellow sandy soil in order to make place for more of that five bushels of dash-eens that I have told you about. Of course I perspired freely; and after working an hour or two I enjoyed a good drink of water more than I can tell you. During the past winter, especially along toward spring, there has been more complaint around here of the "redbug" than usual, and I myself have had some of the "biggest doses" of "redbug poison," I think, that I ever had before since I have been wintering in Florida. Well, one day I asked Wesley if the redbug didn't trouble him. His reply was, "Mr. Root, the redbug never troubled anybody—at least, they don't trouble anybody very much when he sweats profusely. The sweating drowns them out." Since I have been helping Wesley spade up the ground so as to get into a brisk profuse perspiration the redbug poison seems to have let up almost completely. "By the sweat of thy brow shalt thou eat thy bread." The women-folks of our land seem to have caught on to what I am suggesting pretty well, to the full; but if I understand it, it is because of the fashion and not because it gives them health, strength, or vigor. Well, I am very glad to see them get along with lighter and thinner clothing, and clothing of less weight; but it keeps occurring to me that, since this new style of dress was adopted, if it were worn more at home instead of out on the streets it might be better, all things considered, especially for the growing boys and men who do not always look on women in the new attire as they would have *all men* look at their own wives, sisters, and mothers. If I am correct, Terry says that he wears no underclothing except when he goes away from home. When we are outdoors in the field in the tropic or semi-tropic climate I would let the underclothing be pretty much *all* the clothing that is worn. When we go to town, of course we ought to get fixed up a little more decent and a little more presentable. When we go to church on God's holy sabbath, of course we want to look at least respectable. Even *then* I do not believe, however, that

it is incumbent on us to wear the old style of stiff starched shirt fronts. In our present church we have a Bible class of elderly people who sometimes number as many as fifty or sixty. Last Sunday I took pains to notice, and scarcely a man wore a shirt with a stiff starched front.

Now I want to say a word along the same line in regard to the care of the feet. For years I have been troubled with corns, and it has taken a great amount of my time to apply corn remedies, or to provide myself with a keen sharp knife and cut away the troublesome accumulation; and especially during hot weather my feet get hot and uncomfortable. Last summer I told Mrs. Root that I should have to go barefooted or wear some very light women's cloth shoes. But she vigorously objects to this, especially when genteel people want to see A. I. Root; and, by the way, that reminds me that one day down in Florida when I had discarded my shirt, cap, and every thing but my light union underwear and pants, I was out barefooted hoeing my potatoes, when a whole load of ladies and gentlemen who took or read GLEANINGS called to see me. These were people of wealth and culture. When I undertook to apologize, the leader of the party said that was just the way he did at home himself; and I found out afterward that he was a man of large means. Well, when Mrs. Root scolded about my going barefooted, even in the presence of company, I tried at the shoestores in Bradentown to get some of the thin-cloth ladies' shoes. Among the dealers one who came from the North explained that there was no call for any thing of that kind in the South; and when I told him about the troubles with my feet he brought out some Florida shoes. A pair of these shoes are now on my feet as I dictate these lines. There are 21 oblong openings in the upper part of the shoe. In fact, one can look right through the shoe and see the stocking feet. Some of the openings come right above where my most troublesome corns used to be located. Let me digress a little.

Years ago one of my feet became so sore that I was pretty nearly crippled. I went to our family doctor; he said the trouble arose from a *lack of ventilation*. He told me to get an old shoe, and cut some slits through the upper part so as to let plenty of air get in clear around the sore spot, and then Nature would perform a cure without any drugs or medicines; and I used to go to church with that same mutilated shoe. Well, these shoes I found in Florida were made that way, and the openings I have mentioned are disposed so as to be ornamental rather than otherwise. I do not

know whether this sort of shoe is for sale here in the North or not; but it certainly ought to be in hot weather.

Let us now consider our text, or string of texts, a little in closing. The dear Savior exhorted us to beware of thinking too much about what we should "put on;" and I am sure he would not approve for one moment the expensive clothing that is now worn by both men and women who *think* they can afford it. I am not posted in regard to women's dress; but I am told that single garments frequently cost more than a hundred dollars. On our trip home a lady who sat next to us told about a woman in Florida who paid \$600 a week for board and lodging—almost \$100 a day. Her attire was after the same fashion. Our text admonishes us in these words:

"Why take ye thought for raiment?" And, again, "If God so clothe the grass of the field . . . shall he not much more clothe you, O ye of little faith?" We as a people have not only been "overfed," as Terry tells us, but we have many of us been *overclothed*. In fact, I have been overclothed; and until the present time I scarcely knew it. As nearly as I can gather from the Bible, among Oriental peoples in ancient times the clothing not only cost but little, but it gave access to an abundance of air over every part of the body; and not only air but sunshine as well.

I forgot to mention in the proper place that, when I let the Florida sun strike directly on my bare neck, shoulders, and breast, I at first got sunburnt; but in a little time my flesh got tanned and hardened, and it was just delicious to feel the sun and air where I had been having neuralgic pains. Many times when we had cold nights I found it necessary to put on my sweater, and bundle up pretty well. But I would often get busy and forget to dispense with this extra clothing when it was no longer needed. Then I would begin to have my old feelings of lassitude and bad circulation, accompanied with a lack of energy and enthusiasm; but when I got rid of the heavy clothing, and got hold of my hoe and went out in the garden, I felt a new lease of life. I was ready to sing praises, and give an old-fashioned Methodist shout over my "showers of blessings." At my age, when I begin to feel chilly toward sundown, or when the weather changes, of course the proper thing to do is to hunt up the discarded garments until I feel comfortable. The shoes I have mentioned, which I call my "cornerib" shoes, have very thick soles. This keeps the feet dry. Of course you must not get into the mud and water with such shoes, for that would soon result in

wet feet; but the soles are so thick that the feet are kept pretty well up out of the wet. Here is another point:

As we grow older we find our strength failing. Even a fair-sized Bible I sometimes feel to be quite a burden when I have to walk any distance. Well, now, many old people will find it a relief to get rid of every pound of clothing that can be dispensed with—yes, I might say every ounce. When I am going to take a considerable walk, I take my heaviest pocketknife out of my pocket; and if I have any silver dollars I lay them aside—at least as many of them as I shall not need. Young people, full of muscle and strength, may not need these suggestions. There is a beautiful text which I feel will come in well here:

Let us lay aside every weight, and the sin which doth so easily beset us, and let us run with patience the race that is set before us.—HEB. 12:1.

I do not know much about the raiment the Savior wore; but from the pictures and other suggestions we gather, I conclude it was very simple, light in weight, not ex-

pensive, and gave him the full benefit of the air and sun, as I have mentioned. Just one word more about starched clothing:

It is certainly the wrong thing for me; and I hope to see the time when the fashion of making the clothing with starching and ironing will go out of fashion. With the attention that is now being given to this matter of health, there certainly ought to be a reform in clothing as well as in the food we eat. I am sure a style of raiment can be devised so that both men and women may look neat and tidy, and at the same time get the full benefit of both sun and air in the way I have described, especially in hot weather. May God help us to break away from foolish fashions when those same fashions interfere with our securing the best and most robust health. Therefore "take no thought, saying, What shall we eat? or, Wherewithal shall we be clothed?"

But seek ye first the kingdom of God and his righteousness, and all these things shall be added unto you."

Poultry Department

TREADING IN THE FOOTSTEPS WHERE GOD HAS TROD.

Some scientist has said he greatly enjoyed treading in the footsteps where God has trod, or thinking God's thoughts over after him, or something to that effect. If I have not got it exactly right, will some one please straighten me out? Well, lately I have greatly enjoyed treading in the footsteps where God has trod. Let me explain:

I told you last fall that I had prepared to have an electric incubator to run during the winter down here in Florida. Well, when I got here I found they hadn't got ready to give us a current for the whole twenty-four hours. They thought, however, that by the first of January they would be all ready; then it was put off until the first of February. Well, just a little before the first of February we had some cold, rainy, and dark days. The demand for light all day was so much that they finally put it on without giving me notice, as they had promised. When I found out that the current was on I hurried up and fixed the incubator. In order to get eggs enough, I put in part of them one day and part another. I know incubator manufacturers have, almost without exception, declared against such a course. I thought that, under the circumstances, I would risk doing so once more; but just mark right here—I am never going to try any more experi-

ments of *that* kind. They should all go in at the very same hour, and the temperature shall be kept right up from the start to 103 as nearly as I can make it. I want the incubator warmed up and adjusted before the eggs are put in, and then, as I have said, every egg shall go in at just such an hour. The reason is this: I want the chickens all hatched out at one time. If some of them are dragging twenty-four hours or more, there is sure to be trouble—at least that is my experience.

Well, every thing went along 'all right until the eggs began to pip, and one Sunday morning I got a telephone notice that the current would be cut off (in about an hour) all day Sunday. Had they given me notice long enough beforehand, so I could have lighted the lamp and warmed up my Buckeye incubator I wouldn't have cared so much about it; but just imagine the condition—chickens already beginning to pip the shell, the incubator perfectly cold, and a pretty cool morning at that, and on Sunday morning. I lighted my lamp and did every thing I could to warm up the Buckeye incubator quickly; but by the time I got it up to 95 the electric incubator was also just 95, and going down rapidly. The Buckeye, however, got up to 100, and the electric was down to 90, and I decided to make the change. Now, you know every incubator manufacturer, at least nearly all

of them, declare that the incubator *must not* be opened nor the eggs disturbed after they begin to hatch. Another thing, my electric incubator had 60 fertile eggs in it (I have explained before how I manage to keep my incubator full of fertile eggs), and the Buckeye held only 50. What should I do with the extra ten? Let me digress a little.

I have been all winter wanting some sitting hens; but my cross between Buttercups and white Leghorns have never offered to sit. I don't think I even heard a clucking hen until the first of February. Well, about January 1 I asked neighbor Rood if he didn't have a sitting hen he could spare me. He said he had two or three, and I was quite welcome to them. They were Rhode Island Red pullets; but he said he didn't believe I could make them sit after they were removed from their home across the way to our place. It turned out just as he said. I purchased at \$1.00 each three of these great big beautiful pullets that wanted to sit. He said he guessed 75 cents would be about the right price, but I remonstrated. I told him I couldn't think of taking his young pullets, just commencing to lay, at less than \$1.00. Well, true enough, when I got them over to my place, in spite of all the care I could take, not one of the three would sit. He said I might bring them back; but I told him they would want to sit again pretty soon, and so I preferred to keep them. Well, in about a week one after another began to lay, and gave us a goodly number of eggs; some of them every day, and some of them two eggs out of three days, until about the middle of February. Well, one of those Rhode Island Reds (a great big healthy motherly-looking hen) that very Sunday morning, just a little before brother Rood came over, this big fluffy hen was around "clucking." Just as I began to wonder what I should do with the extra eggs that wouldn't go in any kind of shape in the Buckeye incubator, I remembered this clucking Rhode Island Red; and on going over to the poultry-house, sure enough she was on her nest, and fighting furiously when I attempted to interfere with her. So I just took fifteen of those eggs that were ready to hatch and put them under her. I have so frequently taken eggs from sitting hens and put them in the incubator, and *vice versa*, that I didn't anticipate any trouble; and there wasn't any trouble here so far as the *hen* was concerned. The only trouble was this: She seemed to know (or God had told her) that, when she commenced to sit, the eggs should be rolled and turned; and not knowing, evidently, that these eggs were almost ready

to hatch, she kept on rolling and turning them when they should not have been rolled or turned at all. You know all of the incubator-makers say that we should stop turning the eggs on the eighteenth day. In times past, because I couldn't see any particular need of this, I had kept on turning them. You may know the result. Many of the eggs began to hatch when the opening the chick made was on the under side, and the liquid inside of the egg ran down and closed it up, and the chick suffocated. And now a great and wonderful truth began dawning upon my mind. The reason the manufacturers of incubators say we must not turn the eggs after the eighteenth day is because the sitting hen, after about the eighteenth day, entirely ceases from rolling and turning the eggs, and leaves them quiet the same side up until they hatch out. I ought to have remembered this, because once in times past I took some duck eggs that were nearly ready to hatch and put them under a hen that had been sitting only about a week. The consequence was, she rolled and tumbled those poor little ducklings when they were just getting their noses out of the shells until she killed nearly all of them.

Well, these three Rhode Island Red pullets have given me faith in the Rhode Island Reds. Before, I had never fancied them very much; but the sight of this hen that was clucking around preparing to sit Sunday morning, and had some chicks hatching out just twenty-four hours later, gave me faith. After this, when she took the chickens just hatched out in the incubator as soon as they could be safely removed without any objection, it gave me still more faith in the Rhode Island Reds. A cold rainy spell came on, perhaps the coldest we have had in Florida this winter, just about the time of my incubator trouble. Of the forty-eight that hatched, out of the forty-nine eggs that I have already told you about, there are something like half a dozen that might have died had it not been for this motherly sitting hen that was so perfectly willing to take any thing and brood it under her capacious wings, without any objection whatever. Let me explain.

We had two or three inches of rain during twenty-four or (possibly) forty-eight hours, during the middle of February. This is very unusual here in Florida, and almost unprecedented. Well, as all of my poultry-houses had perfectly dry sand inside on the floor, I hadn't as yet paid much attention to drainage. However, such a flood of water wet the floors of not only nearly all of my poultry-houses, but there

was quite a puddle of water in the brooder-house, right close up to the fireless brooder. They stood it pretty well until morning, when the strong and healthy ones were outside on a run, and the weaker ones had no warm place to stay. This is one of the troubles with the fireless brooder. The big motherly hen, in addition to about thirty chicks of her own, spread her big wings and feathers, and mothered every one of these that found it hard to keep warm in the fireless brooder. I tell you, a good motherly sitting hen that won't quarrel with her chickens, no matter whether they are white, black, or yellow, is a good thing to have. I feel just now like saying that the best brooder in the whole world (especially for the poultry-keeper who keeps chickens on only a small scale) is a good motherly sitting hen. When a chick that is not as strong as the rest begins to feel the need of warming up, the great natural brooder (the brooder that God made) is ready to welcome the poor little sufferer and warm up his back and ears and toes. Underneath her warm fluffy feathers he can stick out his little head and rejoice, and thank God for the haven of rest when it is so sorely needed. Yes, for it is a rest and a "refuge" indeed.

Another thing in favor of this kind of brooder is that chickens hatched in an incubator have to be not only taught to drink but they have to be taught to eat. Several times I have found it quite a little trouble to get brooder-hatched chicks to eat bread and milk. When the bread and milk was set down before them, they only looked at it and smelled of it; but after a motherly hen had taken a mouthful in her bill and held it out to them with the accompanying assurance of her voice, the chicks all gathered around, and the most greedy took it from her lips(?) and then when she picked up some more and offered it to them the same way, they began to catch on and began looking for something on the ground, or on the little wooden trough or dish used for their regular food. After she has had the little chicks for a week or ten days, *then* the fireless brooder is all right, especially if you are down here in Florida. The temperature, the coldest we have had this winter so far, is just an even 40 degrees here on our place.

SOMETHING ABOUT INDIAN RUNNER DUCKS.

Ever so many inquiries have come in regarding Indian Runner ducks and rearing ducklings. The most of these are answered in an article already sent in. Just now somebody wants to know what *kind* of Indian Runners I would recommend of the

three that are advertised and talked about. Now, perhaps I am not competent to answer such questions. This is what I think about it. I don't think it makes a bit of difference whether the ducks are black or white or yellow. It does, however, make a little difference in regard to the color of the *eggs*. It is an easy matter to select ducks that will lay white eggs from any of these three different kinds. Somebody recently asked the editor of the *Rural New-Yorker* if, in his opinion, the chickens that cost so much money at the chicken shows would lay any more eggs than other chickens. The good editor, or one of his correspondents, said that, so far as they could learn, it made very little if any difference at all. Poultry shows and the great crowds that gathered there were simply to show chickens that are good to *look* at. Now, friends, especially those of you who are beekeepers, you well know how many years and how much time and money were wasted in growing *bees* that "looked good." When we found bees that were handsome to look at, and were lighter colored than any we had had before, everybody was wanting them; but when we got right down to the facts of the case I discovered (and I think perhaps hundreds of others did) that the good-looking bees, as a rule, did not gather as much honey as some that were not so handsome. Leather-colored Italians, or the hybrids, gave the honey. In almost every neighborhood just now you will find somebody who has been foolish enough (I think that is the right kind of word) to pay \$1.00 apiece for eggs of chickens or ducks, and even more than that, when these high-priced eggs won't produce chickens that are any more valuable for eggs or for table use than those that can be bought at the ordinary price. The question is, what are you after—beauty or utility? If you want to do something for the world about the high cost of living, you don't want to pay 25 or 50 cents or \$1.00 apiece for day-old chickens. Without question, if you want to pay \$5.00 (or perhaps more) for a rooster that has been reared from a hen that has produced *pullets* that give a high record on eggs, it is good sense and real science. In this way you might also pay several dollars for a *pullet* from such a mother.

COUNTING CHICKENS "AFTER" THEY ARE HATCHED.

Our readers will remember that I have said a good deal about fireless brooders here in our Florida climate, saying no artificial heat is needed, even when you take chicks right out of the hot incubator and put them immediately into the fireless

brooder out in the open air. But in the past ten days I have had an experience that has made me think I ought to take back some things I have said. Right during the last week or two of the month of February we have been having a great lot of rain—very much such continued rains as we have here along in the summer; but although I have taken three hatchets out of the incubator this winter, and lost scarcely a chicken, when my forty-eight had to take their first two weeks during this rainy season, there was, I shall have to admit, a *need* of some kind of heat, either artificial or natural. It rained so hard, in fact, that the whole ground was flooded. Every poultry-house on the premises, including the brooder-house, had a puddle, more or less, on the floor. We put ditches around the outside, but the ditches seemed inadequate, for we hadn't fall sufficient to take it away. The chickens stood up bravely for two or three days, then there began to be drooping wings and evident signs of a lack of warmth. I suppose I might have used hot bricks or jugs of hot water; but this was considerable trouble; and I supposed, naturally, that the sun would be out in a little while, and that they would fetch up. The consequence is that I lost six or eight out of that nice hatch of forty-eight chicks from forty-nine eggs.

A week later the big fluffy Rhode Island Red sitting hen was given from another incubator twenty-eight chicks. The floor of her house was a little better drained than the other houses. The drain tiles were laid right under her, and underdrained down to a depth of about 20 or 24 inches, so the ground was comparatively free from dampness—that is, compared with the other houses. Well, this big motherly hen, when her chicks felt chilly or out of sorts, and made that peculiar peep, instantly sat down and invited them under her capacious wings. When we had the coldest night, so that one night there was just a little trace of frost on the roofs of buildings, she kept the whole twenty-eight quite comfortable. During the day she brooded them more or less at intervals, so that no chick felt any inconvenience from getting "cold feet" and feeling chilly. The trouble with the fireless brooder is, in the morning, after strong sturdy chicks have gone out to forage in the open, the feeble ones that are unable to follow them can't get up sufficient heat themselves without their comrades, unless there is some kind of heat like the mother hen, or perhaps artificial heat, and are bound to suffer almost in spite of us. Now, I believe I would rather have a great big

Rhode Island Red hen, or a large fluffy hen of some other kind, in place of any kind of brooder, fireless or with a lamp. Where chickens are raised by hundreds of thousands, of course we have to resort to artificial heat. But, as I have proved several times, one of these big motherly hens will take care of fifty and even seventy-five chickens very comfortably—that is, during such weather as we have here in Florida.

ANOTHER BIG DISCOVERY.

My ducklings are now eight weeks old, and it is quite desirable that they should have a wider range; but there are several reasons why I can't give them this wide range without building more expensive fences. You see the ducks are easily fenced with a two-foot netting, which you can easily step over. The chickens have to have about a four-foot fence which can not be easily stepped over. If we go through into their yard, or out of it, we have got to have gates. Now, I didn't want any more gates or fences, but I did want my ducklings to get through a yard where there were some half-grown chickens, and get a wider range and down to the water. Was it possible to make any opening through the fence that would allow the ducks to pass back and forth freely, and wouldn't admit the chickens? As the ducks and chickens were of about the same size, you would naturally say you don't see how it could be managed. Well, now, just listen. Right close to the dividing fence between the ducks and chickens was one of our underdrains to carry off the water. We dug a hole under the fence and then allowed the water from the underdrain to run over and fill this cavity. The cavity was deep enough so that, although the ducks went in and out without a bit of trouble, not a chicken dared to venture to go down into that mud-hole to get under the fence. Thus you see we had it. The ducks go back and forth as often as they please, but not a chick dares venture through to follow them to get into their yard and eat up their feed and jump over their two-foot fence. Do you say that this mud-hole under the fence will soon get to be very foul? Not so, for we have arranged so that water from the underdrain that goes in at this little pond comes out at the other side and keeps the water constantly changing. As the underdrain didn't carry sufficient water to keep things tidy and sanitary, we carried it up further on to higher ground, so as to get it down where we have a steady stream of running water.*

* About a year ago I told how we make an "artificial spring" by running tiles almost on a level up sloping ground, thus draining the land and getting running water at the same time.

Thus the ducks are not only watered, but they have water to wash off and swim in, and at the same time they have an open gateway where they pass at pleasure, but not a *chicken* can follow.

Later.—Since the above was dictated, the chickens learned, after all, to wade in pretty deep water; but the ducks had also learned the trick of diving, and we have lowered the fence until it almost touches the water; this, while quite agreeable to the ducks, proves a “dead open and shut” on the chickens.

GREASING THE ROOSTS, FLOORS, ETC., TO KEEP OUT VERMIN.

O. W. Mapes, “the hen man,” says in *American Poultry World* that if roost poles are saturated with hot tallow, and the places also where roosts are attached to the building, no lice or mites will ever get on the fowls. Where wood floors are used, say in a brooder house, saturate the floor also with tallow or other cheap grease. Of course, kerosene will do it; but it must be soon renewed, while the hot tallow penetrates the wood and stands for years. Mapes should know about this after his years of experience. Here is what the *Farm and Fireside* has to say in regard to the matter:

BESTING THE MITES AT LAST.

The fight of generations of poultrymen against external poultry parasites seems about to be won if the claims of “Mapes, the hen man,” prove to be borne out. Mr. O. W. Mapes is a poultryman of many years' experience, whose operations have been conducted on a considerable scale and with a good degree of success. His unique ideas for housing and handling poultry have become known to poultrymen in many sections of the country, and for that reason his recent utterances on the complete control of external poultry parasites deserve to have full and fair consideration.

Mr. Mapes now affirms that the long-continued fussing and fighting to keep poultry free from blood-sucking insects is needless. The only treatment necessary is to paint the perches once a year with beef or mutton tallow, covering top, bottom, sides, ends, and roost supports with the melted tallow, leaving no space, crack, or crevice untreated. This is absolutely all that is required to win the fight except to compel every bird to roost on the greased perches. Simple! Easy? Yes. The mite or other brood-sucker that gets a smear of grease gets a dose that ends his career.

We have contended against these minute foes that cause an aggregate loss of millions of dollars annually to the poultry industry long enough. Is Mr. Mapes to be the deliverer?

“EGG SECRETS.”

The *Farm Journal* people not only have a knack of getting out the most attractive-looking poultry books, but their books are “chock full” of valuable information and the finest pictures the world can produce. These books, at the low price of 25 cts., ought to be a rebuke to the authors of some

of the cheaply gotten up “chicken books” advertised in the poultry journals. I am pleased to see the book endorses my plan of placing the eggs on the small end for the first three days in the incubator, or until the unfertile can be tested out to make more room. Now, if this egg-farm of 20,000 laying hens were conducted solely for supplying fresh eggs for table use, there could be no ground for supposing the beautiful book was in any sense an advertisement of their business. We learn, however, on several pages, that “day-old chicks” and eggs for hatching is at least *now* (like the Corning egg-farm) a considerable part of their business. Notwithstanding, I think you want this book. See outside cover page of March 15th GLEANINGS.

MILLENNIUM COMING.

When our great railways begin teaching Christianity (and perhaps to *church members*), are we not justified in believing the millennium is “on the way,” at least? Read the following, which I clip from that excellent little Sunday-school paper called *Forward*, from the Presbyterian church:

THE CLAIM AGENT'S LETTER.

One of the largest railroads in America has a general claim agent who believes in the Golden Rule. He sent a New Year's letter, last year, to every staff officer in his department, and every claim agent employed by the whole big railroad system. This letter embodied a code of ethics, so to speak, for the guidance of his department in its dealings with the public, and it is worth reading and thinking about. Some of its paragraphs are as follows:

“Be polite and kind to the poor. Remember that many an honest heart beats beneath the ragged coat, and a kind word during life is worth the best sermon ever preached after death.

“Do not be deceitful. Tell the truth and take your medicine; it is better for your conscience, the company, and your fellow-men.

“Do not be a colossal knocker. Life is but a flash at best. We should help instead of knock.

“Be honest. Because a claimant is poor, do not take advantage of him nor of his condition. Fate may lead you his way some day.

“Be frank in all things. If a claimant asks your advice, give it openly and freely. If your advice is not taken, your duty has still been done.

“Be courteous. In dealing with the public, do not endeavor to create the impression that you own the road. Remember that the railroad is but the servant of the people.

“Be ever patient. Patience is a virtue which few men possess. If a claimant vilifies you and says all manner of things against you, treat him with all the politeness and kindness you possess; and ere the day has passed he will bemoan the fact that he has made an ass of himself.”

Good Christian rules these, as well as good business counsel. In reading them, it may be interesting to remember that the claim agent of a railroad has not a very easy job. All sorts of claimants, many of them unreasonable, attack him daily.

Now will some one tell us the name of the “great railroad” sending out the above?

Editorial

OUR COVER PICTURE.

OUR cover picture for this issue is the work of our Colorado correspondent, Mr. Wesley Foster, as mentioned in his article on another page. The picture shows weak colonies placed over strong colonies so that the former may share some of the latter's strength, according to the Alexander plan.

MICHIGAN'S NEW FOUL-BROOD LAW.

MICHIGAN has at last an up-to-date foul-brood law. Some years ago it had a county law that was practically ineffective, as such laws usually are, and then, later on, a State-wide law; but this law carried with it a very limited appropriation, and was otherwise defective in many respects.

Two years ago the late George E. Hilton, Mr. E. M. Hunt, and others, exerted themselves to get through a modern foul-brood bill, but were unsuccessful. The beekeepers of the State, however, did not despair. They renewed their efforts again this year, and were finally successful in securing an effective law having an appropriation of \$1500.

The administration of this new law has been placed in the hands of the State Board of Agriculture, and the latter has in turn placed it under the direct charge and control of the State Entomologist, where it should be, Professor Pettit, of the Michigan Agricultural College at Lansing. A competent inspector has already been appointed in the person of Mr. McMillen, of Guelph, Ontario, College.

Later.—Minnesota has just passed one of the best foul-brood laws we have. Particulars in next issue.

IMPORTANCE OF PROTECTING APIARIES FROM THE NORTH WIND.

As spoken of elsewhere in this department we have at the present time, May 9, eight different out-apiaries. As we have more yards this year than usual, several new locations had to be secured. As soon as the roads and weather conditions permitted we took a machine and drove out over our stone roads, seeking possible locations for bees. One spot about five miles out im-

pressed us as being very favorable for a yard. A steep bluff facing the south had at the bottom a nice grassy plot and a stream of running water. As the location was pastured with cattle we tried the experiment of putting the bees on the steep bluff or side hill. The hive-stands were fixed up in such a way that the backs rested on the ground while the front was supported by means of two stakes two or three feet long. In this way the hives were arranged in rows along the bank.

When our State foul-brood inspector in his annual rounds came here to look over our bees he remarked, "By jingo, Mr. Root, I guess I shall have to saw off one of my legs and splice it on to the other, if I stand up in front of those hives." It is a fact that, in order to work the hives, one must stand on one knee and a straight leg on the other. While this is inconvenient, the hives are away from cattle, and right where the sun can strike them nicely, and, most important of all, they are entirely screened from a north wind.

On the 7th of May, right in the midst of fruit-bloom, a sudden cold spell with a north wind came on. This stopped all bees working at all the yards except at this one on the bluff or steep side hill. Here the bees seemed to be working almost as well as at the other yards when the weather was warm. While a chilly wind was blowing strong from the north, the bees from this sidehill apiary were in a perfect roar. They would circle around in front of the hives, and, meeting no cold, would start off for the fields. When once started, they would not go back, but go to the fields, and so they roared all day. Whether they were gathering nectar we do not know; but busy they were.

Our State foul-brood inspector worked here all the afternoon in comfort for the bees and himself also, and he didn't saw off his leg either.

It is proper to remark that he found no foul brood at any of the yards except at one of the outyards, and that was a mild case. That colony was promptly burned.

•THAT AUTOMOBILE TRUCK FOR OUT-APIARY
WORK A GREAT SUCCESS.

The little machine has been kept busy in hauling bees and equipment to eight different outyards. It is capable of a maximum speed of 22 miles an hour when running light, and carrying a maximum load of over 1000 lbs. We can take easily 25 colonies at a load; and as it requires only a very short time to make the round trip, we can take another load of 25 and make up a whole apiary in the forenoon.

Our policy last winter was to haul bees home on a sled when snow was on the ground, winter them in our mammoth cellars, and then in the spring, after the roads hardened up, put the bees back again in their several yards with the auto truck before mentioned. The scheme is working out to our fullest expectations. Never before have we been able to secure any considerable amount of honey from fruit bloom; but the little auto truck has enabled us to scatter our bees early in the season, and carry them long distances to where the fruit-trees are located. In one case we had only ten colonies in a cherry-orchard; and in another case we had 40 colonies in a fifty-acre apple-orchard. After we began locating bees in the fruit regions, the farmers all around us began to ask to have bees put on their places, and next year we propose working for fruit-blossom honey as we never have done before.

While we shall not get any honey in supers to speak of, it is worth something to have the brood-nests filled with fresh honey, and brood-rearing in all stages of development. It is worth something to have fruit-men ask to have bees put on their places, because this saves the cost of rental.

As soon as the fruit-bloom season is over we shall move some bees from fruit-yards where clover is scarce to localities where it is abundant. This can easily be done with a light truck at comparatively small expense. It does not make any difference whether the entrances are perfectly tight all around. When the bees are once on the road, the fighting qualities are taken out of them; and even if they do get out, as they sometimes do, there are no horses to be stung. The truck we have is called the Commerce, and was made in Detroit by The Commerce Motor Car Co. Ours cost \$875, equipped with top, lamps, and all complete.

On one occasion our boys went out to a distant yard prepared to stay over night and sleep in the truck (which is covered), get up early, close the entrances, and drive back. But the bees fortunately went to bed early. We closed them up and came back that night.

To show you the possibilities of the truck, our yard-man who operates it and works with the bees at the same time went off on a trip yesterday to a place 60 miles distant. He left here at 6:30, loaded up, got his dinner, and was back here by 4 o'clock. The truck is used daily to carry the boys to the outyards; but when they go they always carry something with them. One crew of three men are now running seven yards. These will be operated for the raising of bees for nuclei and pound packages, for the production of honey, and the rearing of some queens.

SCHOOL FOR BEEKEEPERS IN MASSACHUSETTS.

PERHAPS the most complete—certainly the best equipped—school for instruction in apiculture is the one located at Amherst, Mass., at the Agricultural College. While there are regular students taking a course in apiculture under Dr. Burton N. Gates, the Agricultural College announces a special two-weeks' school for beekeepers to begin May 28, followed by a convention on June 11 and 12, at which time a number of prominent beekeepers from all over the United States will be present to give addresses. The following is the announcement that has been sent out:

The faculty and the courses which they will give are as follows: Practical Phases of Beekeeping, Dr. Burton N. Gates; Crops for Honeybees, Prof. S. B. Haskell; The Relation of Bees to the Pollination of Plants, Dr. George E. Stone; Structure of Bees, Mr. I. W. Davis; Bees and Beekeepers' Supplies, Dr. James B. Paige.

Students will have the use of the regular apicultural equipment of the college, consisting of about two acres with fifty colonies of bees and a modern building constructed especially for the teaching of practical apiculture. Practically every device used in American apiculture will be shown, it being the aim of the department to procure new inventions as fast as they appear, for the purpose of study and comparison. A library of over 700 volumes and papers of apicultural literature will also be available to students.

It has been found necessary to limit the registration to fifteen, and applications will be accepted in the order received. A registration fee of \$2.00 will be charged, and will constitute the laboratory expenses.

For bulletins or other information address Prof. W. D. Hurd, Amherst, Mass.

Besides the lectures there will be field-day work, showing how to take honey out of the hives, how to extract—in fact, do a hundred and one things connected with the general work of handling bees. The College has erected a modern bee-building for wax-rendering, extracting—in fact, for doing any kind of work connected with a modern beeyard. It is equipped with the latest machinery, including a power extracting-outfit, with a honey-pump.

The field day will be an exceptional op-

portunity for many of the veterans, and certainly for all beginners, to learn the very latest that there is doing in the way of taking honey from the bees. Particulars can be secured from Dr. Burton N. Gates, Amherst, Mass. When we say that, in our opinion, there is no other school of apiculture that will compare with this one, perhaps we should except the one located at Guelph, Canada, under the direction of Mr. Morley Pettit. Both are doing splendid work; but the school at Amherst has never been better equipped than now. In a recent letter received from Dr. Gates he writes:

This course, the spring work for the layman, is one of six courses in beekeeping scheduled in the institution. They are: Two courses for the regular college students, the four-year men; a ten-weeks' winter course for the winter students; the spring course for the layman; a two-weeks' summer school; besides the correspondence course. This outline, I believe, exceeds apicultural instruction given elsewhere. Moreover, you know that our equipment is by far the most complete, especially our collections.

THE HANDBOOK OF APICULTURE.

DR. ENOCH ZANDER, of Erlangen, Germany, has written a book with the above title.* It is in three parts, each part to be had separately. No. 1 is devoted to foul brood and its treatment. It is a practical condensation of all that is now known on that subject, and fully illustrated with pictures enlarged by micro-photography, whereby germs invisible to the eye are enlarged to half an inch in length; but it must not be inferred from this that the photos are better than any drawings.

Dr. Zander is one of the men most able to speak on the subject of foul brood, and he has covered the ground in this book of 31 pages and 16 illustrations. In speaking of the rapid multiplication of the germs which cause foul brood, he says one bacterium will throw off a shoot or bud every twenty minutes, so that in 24 hours it will have multiplied to 16,500,000, and in 48 hours to 281,500 millions of millions.

Dr. Zander divides brood disease into sour brood, the germ of which, as the doctor claims, is *Streptococcus apis*, basing this claim on Maasen; foul brood, due to *Bacillus alvei*; brood pest, due to *Bacillus larvae*, or *Brandenburgiensis*. The peculiarities are described minutely.

But Dr. Zander does recognize *Bacillus larvae*, discovered by Dr. White, as the cause of American foul brood, or what he calls "brood pest." At the time his book was published, or written, rather, he, of course, did not and could not know of Dr.

White's further discovery of the cause of the other brood disease, or what we call European foul brood—*Bacillus pluton*. As we understand it, Dr. White has proved that *Bacillus alvei* is non-pathogenic—that is, not disease-forming; and although for many years it has been supposed to be the cause of foul brood, the evidence is pretty clear now that it has nothing to do with either of these diseases, although present with *Bacillus pluton*, and sometimes found with *Bacillus larvae*.

Immediately following the work referred to above comes another from the busy pen of Dr. Zander, entitled "The Structure of the Bee." As its name indicates, it is devoted entirely to a description of the various organs of the bee; and if any thing has been omitted we do not know what it is.

This work contains 182 pages, including 149 illustrations. After this we have twenty full-page plates, showing in all 75 enlarged views of bee anatomy, photographed in almost every instance from the organ itself.

THE CALIFORNIA HONEY CROP A FAILURE.

THE following telegram, received just as we were looking up this last form, will explain itself:

Season is practically closed, with no honey in sight; orange almost a complete failure; sage not yielding; will be the lightest crop since 1904, and may be for twenty years. Same report from all sage and orange districts, no crop. Further particulars to follow for June 15th issue.

Redlands, Cal., May 12.

P. C. CHADWICK.

We may add that we have asked our correspondent, Mr. Chadwick, to send us telegraphic reports just as we go to press, so that we may give our readers the very latest regarding the honey-crop conditions on the western coast. The foregoing is the first of a series of night telegrams.

The prospects for a white-clover honey-flow in the eastern States were never better than now. It is beginning to get a little dry, but a rain would set every thing booming. Fruit bloom generally has been good.

MR. TYRRELL RESIGNS THE EDITORIAL MANAGEMENT OF THE REVIEW.

JUST as we go to press news has come that Mr. Tyrrell, Secretary of the National Beekeepers' Association, has resigned his position as editorial manager of the *Beekeepers' Review*, the Association organ. Mr. E. D. Townsend, one of the directors, takes his place, and the publication will be continued hereafter from Northstar, Mich. Overwork has compelled Mr. Tyrrell to take this action, and he will now devote his energies to the work of the National.

* Zander, E., Erlangen, 1911. *Handbuch der Bienenkunde*, in Einzeldarstellung. Eugen Ulmer, pub., Stuttgart. In three parts, of about 30 pages each.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

THOSE BRICK records, p. 233, are ahead of book records in one way—you can see at a glance the whole apiary without turning leaves. But you must be in the apiary to see the bricks, and you can see the book miles away from the apiary, and plan accordingly. Besides, you often want to consult the records weeks or years afterward.

G. M. DOOLITTLE, there's much in what you say, p. 252. The beekeeper cusses the commission man; but when the beekeeper gets in a tight corner it's might convenient to have the commission man help him out. Allee samee, if some of the middle business can be cut out, it will be just so much to be divided between the producer and consumer.

A GREAT honor has come to me. I've been notified that I'm eligible to become a member of the Burbank Society, which admits only choice specimens of humanity like myself. And it costs only \$150. Could one of you kindly loan me \$150?

Later.—I've just learned that a man as common as A. I. Root is allowed to be a member. Also that, instead of \$150, it costs \$151—a dollar more than I can afford. I think I'll not "jine."

You think, Mr. Editor, p. 284, that with immense buckwheat crops one might get more honey by dividing before the early harvest. Exactly what I tried to express. But when you hint that stimulative feeding might make early division all right for me, we part company. I've some question whether stimulative feeding would make my bees build up sooner; at any rate, you've got to "show me" before I believe that any amount of stimulative feeding will allow me to divide before clover-bloom without cutting down my honey crop. [We did not mean that stimulation would make early division all right for you. We really do not see how it could unless you can postpone your honey-flow a month or six weeks.—Ed.]

YE editor, p. 284, threatens me with having the whole fraternity down on me if I insist that "Al honey is superior, irrespective of quantity, to sugar syrup" for wintering bees. I don't like to be squashed that way, but I guess I'll have to stand it, for that's exactly what I believe. [That is right, doctor—stand by your guns; but we hope you will not be shot to pieces. Joking aside, possibly you are right; but we believe we are entirely within the truth when we say that it is and has been within the line of orthodoxy to recommend sugar syrup in place of honey as a winter food; that when either is

sealed in the combs the syrup is not only cheaper but better. Now, if we are going to be shot to pieces by this bit of orthodoxy, blaze away. GLEANINGS will furnish the battlefield.—Ed.]

My reason for not painting hives is economy, according to p. 232. That's a minor reason; and if it were the only one my hives would all be painted. My first reason was that Doolittle approved it. My main reason is the same as his—it's better for the bees. As one little item tending in that direction, I may say that one winter I had moldy combs in only one hive, and that was the only painted hive. [It is hard for us to believe that the paint on that one hive made all the difference between mold and no mold. We suspect that if you would try the same experiment on a larger scale you would not be able to detect any difference. Are you *sure* there is real economy in not using paint? Is it not a fact that an unpainted hive will gap at the joints more quickly than one that has been painted, and that an unpainted cover will twist and check so that it will not fit? Is it economy to let robbers get through these cracks? If it is economy to let our hives go unpainted, would it not be economy to let our houses go the same way? Say, doctor, here is such a good chance to "jab" you and Mr. Doolittle that we could not resist.—Ed.]

COMB-HONEY quotations have an unusual aspect. As is usual, the price toward spring dropped perhaps two cents. The unusual thing is that now, before any thought of new honey coming in, the price has gone up again where it was. I wonder just why this year should differ from other years, when it stayed dropped, no matter how scarce. [The markets have been more thoroughly cleaned up of *good* comb honey than ever before. There is a plenty of odds and ends and No. 2 and candied comb honey, but there is a great scarcity of No. 1 and fancy. Furthermore, intelligent and persistent advertising is now being carried on more extensively than ever to push the sale of both comb and extracted honey. If you will take a trip going through some of the large cities of the United States you will see that both comb and extracted honey are being put up more attractively than ever before. The packages, both of glass and tin, have the same professional appearance as other food products in glass and tin. Heretofore that has not been true. The day of cheap labels on cheap amateur-looking packages has gone by.—Ed.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

Mr. H. G. Quirin, p. 115, Feb. 15, is quite right in his statements that the prolificness of a queen does not depend on her size. I, too, have sometimes had a very small queen prove one of the most prolific in the yard. * * *

Mr. J. L. Byer inquires, page 76, Feb. 1, if foul brood is more virulent at times than others. I will say that this refers to European foul brood only. American foul brood in all localities seems to move on in the same slow sure way to the end. * * *

Notice of the death of D. H. Coggsball, Feb. 15, recalls to mind the pleasant day that I spent with him in his Florida home a year ago. I almost envied him his delightful home, surrounded with fruit trees and every thing to make life desirable. But he has been called away, and we are reminded again that this beautiful world with all its charms is not our permanent home. * * *

That picture, page 83, Feb. 1, of an orange tree bearing a crop of icicles instead of oranges is indeed a queer sight. In much of California as in Florida and other parts of the extreme South, frost is the weather condition most dreaded, while in the North a winter free from snow or ice is equally to be feared, as it will be almost sure to work mischief to the clover and fruit crops later. * * *

The editor says, page 73, Feb. 1, that the only thing fit to use during winter for closing entrances of hives when moving them is a light snow. May be in Ohio; but in Vermont we have moved a good many yards of bees in winter on sleds and found cotton wool to work perfectly. It is not always we have the light fluffy snow to use, and we always use cloth over frames somewhat porous. * * *

Mr. Chadwick says, page 75, Feb. 1, that in California they have a law compelling the use of movable frames. So far so good; but does such a law make the owners use them in a sensible way? Of what advantage is a movable-frame hive when the frames are two inches wide, or combs built crosswise of the frames, or a honey-board and bottom-board both nailed securely to the brood-chamber? * * *

On page 115, Feb. 15, Mr. David Roberts gives some facts in regard to the value of shelter in wintering bees. One thing he

seems to have overlooked; and that is, to give plenty of ventilation above the packing. If this is given, there will be little trouble from excessive moisture in the packing above the bees, no matter how carefully sheltered or protected. But do not shelter so much as to induce the bees to fly in weather so that they will get chilled and never return. * * *

Dr. Miller seems to think, page 74, Feb. 1, that there is no more enthusiasm among the young beekeepers of to-day than among the beekeepers of fifty years ago. I guess he is right; but I have been wondering if we have as many young beekeepers to be enthusiastic as forty or fifty years ago. In the pictures of the conventions we see in bee journals, most of those represented appear to be old or elderly men—very few young men. I sometimes wonder if the old men attend the conventions and leave the boys at home to look after the "chores." * * *

Mr. Chadwick, page 110, Feb. 15, speaks of the viciousness of bees in California; and I have noticed here in Florida they seem in most of the yards I have visited much crosser than in the North. I wonder if this is generally true; or is it because the bees I have seen handled were handled out of season or in the colder part of the year? Bees in Florida appear to be more sensitive to weather conditions than in the North. Bees in the North seem willing to work when the temperature is cooler than they will work here; and, again, they will stop during the hottest part of the day here, apparently on account of the heat, when they would not think of stopping in the North. * * *

I am under obligation to Mr. Wesley Foster, page 128, Feb. 15, for correcting me in regard to the rapid granulation of alfalfa comb honey. As I have seen the statement in print many times, and so far have never before heard it contradicted, I supposed it was a fact. I also passed through Colorado some years ago; and while stopping at a hotel over night I called for some honey at the breakfast table; and after considerable urging I secured a little granulated comb honey. This was early in November, and tended to confirm my views of the granulation of alfalfa honey. So, then, it is sweet clover, alfalfa, cleome, and wild flowers mixed that makes the trouble. Glad to know it.

Beekkeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

As the season advances and the trees and the grasses and weeds begin to turn green, and we keep time to the hum of the bees, we find many a beautiful picture before us that is worth taking. In this day of easy picture-taking, much pleasure can be derived from snapping the numerous things that have helped us to make certain work much more easy. Who will take pictures of interesting things this season, and send proofs to us for publication, together with a few notes to accompany them?

OLD COMBS AND BULK COMB HONEY.

The following question was sent by a western subscriber for our reply:

I have 200 shallow extracting-supers filled with drawn comb made from full sheets of medium brood foundation, having been worked above excluders. These are all wired. What I want to know is whether they will make good bulk comb honey by putting them on the hives this spring and letting the bees fill and cap them. So far as the wires are concerned I think I can pull them out when the combs are finished. But I am not aware whether or not these old combs will be tender enough to make a merchantable grade of comb. They have been used only two seasons, and are clean and in good condition.

I note also in GLEANINGS, Nov. 15, your remarks as to sizes of containers of bulk comb honey. As to the 12 and 6 pounds cans, will you kindly advise me where to buy them, and whether or not you get the cases for these *with* the cans, or do you buy the cases elsewhere? The factories from which I have quotations quote the cans alone, and make no reference to cases.

Extracting combs several seasons old should not be used under any circumstances for bulk comb honey, even if they are nice and clean, and especially not if they are built from medium brood foundation. For bulk comb honey nothing should be used that is not strictly newly built comb honey, and in all respects as nice and tender as your section comb honey that you are now producing. Nothing inferior to this should be put up as bulk comb honey. It is strange that the idea prevails in the minds of some beekeepers that almost any thing can be used for bulk comb honey; but it should be understood that bulk comb honey as produced in Texas, where this product as it is put up here originated, is nothing but what strictly section comb honey would be, produced in shallow frames, cut out and packed in nice clean cans, etc., of regular or standard size packages.

In our methods of manipulating the colonies for best results in comb-honey production we make use of shallow extracting-supers on all our colonies for producing bulk comb honey. These are left on the hives during the winter, and provide extra breeding room in the early spring in addition to the brood-chamber below. This in-

sure extraordinarily rousing colonies of bees for the honey-flows later. As the first flow comes on, these extracting-supers are already partly full of honey from the scattered sources during the spring, and all the honey that was not used during the early breeding season. As the flow begins, these are raised; and the new supers, filled with *full sheets of thin surplus foundation* in the frames, are slipped in between them and the brood-chambers. The bees go to work at once, and seem to try to fill the empty space with a vim that can not otherwise be obtained. After this the usual method of tiering up supers is practiced as needed during the honey-flows, exactly the same as in section-honey production. You will find, therefore, that the 200 supers with combs are a valuable investment, ready to be put on the hives in the spring to catch the early scattering honey. The extracted honey will be needed, and more than you will be able to produce in these supers.

These same supers will come in handy at the end of the honey-flows, to catch the scattering honey as the flows close. By having the honey extracted from these supers they are ready to go in the hives as soon as it is too late to give any more supers with foundation. Much honey is gained by this practice, both in the early spring and after the honey-flows, and the colonies are in better condition to give larger yields than when the old methods are practiced. Besides, we need much extracted honey, and we produce some of it at a time when it would not be profitable to produce bulk comb honey. The 200 shallow supers with combs are worth a great deal more, therefore, if used as suggested, than if they could have been used for bulk comb honey; and if shallow supers are used in this way on all colonies (especially if our number of colonies is large), the extra profit obtained amounts to an enormous item.

We have not bought any of our honey-cans without the cases, more because it has been more convenient to buy them with the cases; and then because we have not had the time nor the facilities to make our own cases. We understand that some beekeepers buy the cans in bulk, and gain by making their own cases. Here in Texas there are a number of dealers in honey-cans from whom we get our supply usually. Many car lots of these honey-cans are used in this State each year. Arrangements can be made direct with some of the can companies, especially if a carload of cans can be used at one place.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

TREATING PARALYTIC COLONY BY CHANGING HIVES AND COMBS.

Two cases of paralysis developed in my home yard of 16 colonies. They were the worst I ever saw. I waited day after day, hoping to see the bees improve, for as a rule this trouble is overcome by the bees themselves after a time. No improvement came, however, and they continued to leave the hive until early in the morning when there would be dozens and sometimes hundreds crawling and quivering on the ground. In one colony the force of bees dwindled until they were barely able to cover their seven frames of brood. I secured a clean new hive in which I placed one clean empty comb and some full sheets of foundation. The entire colony was shaken into this hive, and the brood was given to another colony, the result being that I have since seen no sign of the disease, and the bees of that colony are drawing their foundation rapidly. Just what was responsible for the cure I am not able to say, for I had little idea that a cure could be completed so quickly; yet here is the colony before me without any sign of the disease, while the other one still has the trouble badly, with no sign of improvement. I intend to let them alone for a time in order to see whether they continue to dwindle. The cure may be due to changing to a clean hive, or it is possible that being driven to comb-building and the use of much fresh nectar may be the cause of their recovery.

CHANGE IN INSPECTORS.

"Bob" Heron, the much-complained-of inspector of San Bernardino Co., has at last been removed by the County Board of Supervisors, and thus the curtain falls on the last scene of a ten-years' fight for his removal. And, strange as it may seem, the man who led the winning charge with the hope of getting the place has fallen in the battle. Mr. M. Segers, Jr., who circulated a petition for the place, and had the backing of the County Association as well as most of the beekeepers of the county, fell, as nearly as I am able to learn, a victim to his own thoroughness. He made the statement before the supervisors that he would take no man's word for the condition of his bees. When questioned about his father's he said the same. The young man was right; but that was too thorough for our supervisors, for it would cost some money. But how about the inspectors for scale? Do they go to the orange-rancher and ask

him if he has any scale? No! "Not on your life!" They just walk in and inspect. If they find scale, the orchard is fumigated without question, and that is the only sane way to go at it. Mr. M. J. Meeker is our new inspector, and we doff our hats to his authority. I will do so with the best of grace, though I fought him in favor of Mr. Charles Trout last fall, for I believed Mr. Trout was the best man in the county at the time for the place; but Charley was too young and ambitious to take the place, and is now making his way creditably through medical school.

A DISCOURAGING OUTLOOK IN CALIFORNIA.

Conditions in this part of California seem to me to be about as perplexing, disappointing, and discouraging as any time during the past ten years. The sage was frozen and badly damaged, the wild alfalfa was also nearly all killed (and this is a source that, while not at all appreciated when coloring our lighter grades of honey, in ordinary seasons it would be a great help in a season like this). We had hopes of a fair amount from the sage in case of late rains, but they did not come. We still had the orange. Though it too was badly damaged, the buds began to appear and to show signs of a good bloom; but they dropped rapidly before they opened, and nearly one-half of them never opened. It now develops that those that are blooming do not contain the usual quantity of nectar, and are passing out of bloom rapidly.

My scale colony showed a gain of 10 pounds to-day, April 26; but under old-time conditions they should have reached the 15-pound mark. Conditions are not so bad in some localities. Much of the orange toward the coast is in fine shape, due to the trees not being so badly frozen that they lost their foliage. On such trees the bloom is about normal, and should produce the usual quantity of nectar. More rain has fallen in the counties of Los Angeles, Ventura, and Santa Barbara as well as further up the coast than in the inland district, and some sage honey may be secured in those counties. But our chances inland are about as poor as one could imagine. One poor season is not so bad; but when they come in pairs and even three in succession, it makes us wonder if the bee business is really worth while. But old conditions will return to those who hang on, and then we shall be glad we persevered until a better day dawned.

Conversations with Doolittle

At Borodino, New York.

IMPROVING THE BEES.

"Mr. Doolittle, the ideas you advanced in regard to longevity of bees, and selecting stock along that line, are well worth studying and putting into practice. But are there not other lines of improvement which should be worked out as well as this one? Be kind enough to tell about some of the other things which go toward making *better bees*, and how you were led to your present standard of excellence."

"Without question, the prime idea of all who keep bees is the profit they will give. I think I should be quite safe in saying that, if they cease to yield a profit to their owner for several years in succession they would cease to have owners. That there is a vast difference in the profits from the different colonies in the same apiary was something I found out fully forty years ago when I had nothing but the old black bees to work with. One colony, or a majority of the colonies in the same apiary, would often give satisfactory returns at the end of the honey season, while others just as favorably situated, and in equally good condition in the spring, so far as I could see, gave little or no profit. This trouble was laid at the door of the German or black bees when the high praise of the Italians was first being sung in the sixties and early seventies. But a careful trial of the Italians showed that, while they were a more profitable bee than the blacks, yet they were no less subject to this variability in yield at the end of the season.

"A similar difference in stock is also noted by our dairymen. Certain cows in their herd can not be bought at any price, while others are an absolute bill of expense to their owners unless their carcasses can be turned into beef. Hence an effort is constantly made to propagate the good qualities and eliminate the bad. Now, this is just what every apiarist should do with the bee. And it is something which the majority of beekeepers have sadly neglected, although much more thought and effort have been put forth along this line in the last few years.

"We should start with the *best* race of bees. The Italian I take as the best domesticated honeybee yet brought to public notice, which I think is the verdict of the world's best apiaries of the present time. They are quite largely proof against the wax-moth and its larva, and very successfully hold out against the ravages of European foul brood. They rarely desert their

hives in early spring, no matter how moldy or foul their hives may have become through a disastrous winter. In one case, some 35 years ago, when colonies of black bees were deserting their hives by the score, not an Italian colony did this. I had a colony of these which numbered just 82 bees and the queen, by actual count, on May 15, and yet they held their hive with filthy combs, and protected their stores from robbers, building up so as to give quite a surplus of comb honey from buckwheat, while fairly strong colonies of black bees deserted combs and hives which were comparatively sweet and clean, or suffered their stores to be carried off by robbers.

"However, the main point of excellence in the Italian bees lies in the fact that, whenever a small amount of honey is obtainable, they are up and at it, often making a gain in stores while other races of bees require feeding to keep them alive. And as the profit side of beekeeping must come largely by way of the *stores* gained, after experimenting for years with all other races of bees, and proving that, for this locality, none others were equal to the Italians, I have decided that they are the *best* bees to use in carrying out any improvement.

"And now we come to 'the different lines of improvement' you ask about. In my late article I put *longevity* at the head, and above prolificness of queen, which was considered during the past to be the highest point to be worked for. Having the longevity part established, then efforts toward an extra prolificness of such queens will be in order. Then I would prune out every colony showing traces of black or other inferior blood. Next I would kill all queens which produce vicious bees. I consider the keeping of vicious bees only on a par with keeping a vicious cow or horse. Any of them are a danger, and a constant nuisance.

"Another class of colonies to be disposed of is that which fails to winter well or to give satisfactory results along the lines we are working, though in appearance and temper the bees may be faultless. These should have their queens replaced by others which we have reason to believe will be more to our advantage. In a large apiary it is often hard to account for the failure of some colonies in coming up to the standard we have set. But with such cases it is always safe to abolish the queen, providing one instead which was bred from the mother of the colony which has given the best results in all points under consideration."

General Correspondence

SWARMING CONTROLLED BY REVERSING THE ORDER OF THE BROOD-FRAMES AND REMOVING THE QUEEN

BY H. D. MURRY

When I began running out-apiaries in 1906 I had a plan for controlling swarming that had only one fault—it failed to control. It had been a good plan in another locality, but it failed to work here. I saw that I had to do one of two things—find a plan that would succeed here or quit running out-yards.

Just at this time Mr. G. M. Doolittle was telling through GLEANINGS how he built up an outyard and divided it just at the beginning of the surplus crop, and got a crop of honey from both divisions, prevented swarming, and made 100 per cent increase. I was favorably impressed with the plan, but it bore some resemblance to the plan that I had been following, and I knew that it would not work here, if followed just as Mr. Doolittle practiced it.

The same year, Mr. J. L. Stachelhausen, of Cibolo, Texas, told, in the *American Bee Journal*, what causes swarming. According to Mr. Stachelhausen it is a congestion of the brood-nest and a surplus of nurse-bees. He explained that, by splitting the brood-nest in the middle, and turning it wrong side out, the congestion could be broken. Every apiarist knows that the bees build their brood-nest in a spherical form. The combs in the middle of the nest contain the most brood, while those in the outer part contain the least. To perform the operation we reverse the order, placing those with the least brood in the center, and those with the most brood on the outside of the brood-nest, just as if we were to split an apple open and turn the convex sides together. In doing this we do not place any combs without brood in them between combs containing brood. The bees go to work at once to re-establish the spherical form of the brood-nest, and in doing so they fill out the center comb and extend the brood into the adjacent combs outside the brood-nest. By this plan, reversing brood every ten days or so, we can delay swarming till we get the brood-chamber full of brood. Then, unless we do something to prevent, there will begin to be a surplus of nurse-bees—that is, there will be more chyle accumulating in the stomachs of the nurse-bees than the brood can consume. Mr. Stachelhausen maintained that these nurse-bees with their overloaded stomachs grow restless and bring on what is known as the swarming fever. To

prevent this, as soon as the brood-chamber is full of brood, excepting the two outside frames, he advised that we remove two frames of sealed brood, putting in their place empty combs or full sheets of foundation.

Well, all that seemed plausible to me, but it was not complete, according to my ideas. So I turned to Dr. Miller's "Forty Years Among the Bees." I found that, in order to prevent swarming, he caged the queen for seven days. The idea occurred to me, "Why not remove the queen and start a nucleus with her and let her be laying during that seven days?" So from these three plans I evolved the one following, which has been a complete success so far as I am concerned:

As soon in the spring as the bees begin to build up I go over them; and where they have brood in four frames or more, I reverse the order of the brood-frames, as explained above. I do this every ten days until the brood-chamber is full of brood, excepting the two outside frames, which should be full of honey and pollen. Then I remove the queen with two frames of sealed brood, and start a nucleus with her. Twenty-four hours later I give the parent hive a ripe queen-cell. In ten days or so there is a vigorous young queen laying in the hive, and all inclination to swarm is over for that honey-flow.

When I remove the queen I replace the two frames, taken with her, with empty combs or full sheets of foundation, placing them near the center of the hive with two frames of brood between them. The nucleus may be built up later by adding brood taken from other hives that have become full of brood; but a queen removed early in the season will usually build up strong enough to winter without any assistance except the addition of empty combs or full sheets of foundation. This plan of removing brood will just as effectually retard swarming as the famous(?) Jones plan of shaving the heads off the brood. The principle in both plans is the prevention of a surplus of nurse-bees. Any thing that breaks the continuity of egg-laying in the hive for several days will retard swarming.

At each operation, reversing brood or removing the queen, I destroy all queen-cells in the hive. I hardly ever remove the queen and start a nucleus unless the colony gives indication of wanting to swarm by starting queen-cells.

Some will want to know where I get the queen-cells to requeen. If I am visiting the

yard every ten days. I can remove the queen from a strong colony, such as I want to breed from, and there will be cells there on my return ten days later, or the eleventh day when I want to requeen. However, I prefer to introduce the cell at once, upon the removal of the queen, by placing it in a cell-protector and placing that on one of the combs in the usual way. This saves an extra trip to this yard. Another way to get the cells is to have a queen-rearing yard, and carry the cells to the yard for all the increase one wishes to make.

By following this plan there is no let-up of work in the supers as there is by the shaking plan or any other plan that I ever tried, but work goes right along as if nothing had happened. In testing this plan in 1907 I tried it in two yards, with the result that there was no swarming in those yards. I made 100 per cent increase, and got more honey per colony than in any other yards. We thus have the matter of increase in our own hands. If we wish no increase, we may kill the queen and requeen as described above, or we may cage the queen as per Dr. Miller's plan.

Mathis, Texas.

MODIFICATION OF THE BALDRIDGE PLAN FOR CURING FOUL BROOD

Running the Bees from the Diseased Colony into a Healthy Colony

BY CHAS. M. MUSGROVE

The foul-brood situation in this part of Berkshire Co. is discouraging. Since the inspection in 1911, nothing has been done except by individual beekeepers; and in many cases where disease was found in 1911 nothing has been done in the line of treatment. The consequence is, we are surrounded with diseased colonies to such an extent that I, for one, made up my mind that I would go out of the bee business unless some way could be found whereby I could control matters in my own yard independently of the surroundings.

In the fall of 1911 Dr. Stockwell, of Stockbridge, Mass., at our beekeepers' meeting read a paper in which he argued from a medical standpoint that it is possible, by constant selection, to develop a race of bees that will be practically immune to the disease.

With every method of treating foul brood, so far given to the public, there is constant danger of spreading the disease through opening the hive and shaking out honey as well as bees. With the Baldrige plan the shaking is eliminated; but even then in opening the hive and catching the queen

there is danger that healthy bees will get some of the honey. Perhaps with experts there is no danger; but we are not all experts. In any case, if we wait according to directions until the beginning of the honey-flow, and then treat by either plan, our harvest is over before the bees have time to build up strong enough to take advantage of it.

In my experiment I have used the Baldrige plan as part of the treatment, and Dr. Miller's plan for requeening comes in also.

Early in May, 1912, when I found colonies with European foul brood I immediately closed the hives as they were before, and placed by the side of each an empty hive. This, I think, is an important step in the treatment.

Instead of doing any thing more with the diseased colonies, which we will number 1, 2, 3, 4, and 5, I proceeded to treat a colony which did *not* have the disease.

In 1911 I had one colony located between two diseased colonies which did not contract the disease, and which produced more comb honey than any other which I had. I went to this colony, which we will call No. 6, and commenced feeding for the purpose of forcing a swarm. The result was, that on May 18, which is very early for this location, I had a large swarm. This was hived in the usual way. Parent colony No. 6 was removed, and the new swarm put in its place. So far there is nothing new.

I then went to colony No. 1, removed the empty hive before mentioned, and put No. 1 in its place. Then I put No. 6 (which had just cast a swarm) where the diseased colony had been. The result, of course, was that most of the flying bees from No. 1 went into No. 6. Then in the evening I placed over the entrance of No. 1 a hollow tube extending to about the center of the entrance of No. 6, and ending with a Porter bee-escape, so that, as bees from colony No. 1 came out they were *forced* to enter No. 6.

No. 6, being reinforced with the bees from No. 1, became so strong that, as soon as the young queen could fly, they cast a larger swarm than the prime swarm headed by a young queen. This swarm gave me more honey than any other I had. Colony 6 swarmed the second time; was removed, and the new swarm put in its place without removing the bee-escape tube from No. 1. The remaining bees and hatching brood reinforced this new colony, and, for a time, two queens were working for the benefit of this colony.

Colony No. 6 was then taken to No. 2, and the same process repeated. In this way I treated five diseased colonies from hive No. 6—getting, in place of five diseased

colonies, five strong ones ready for the harvest. From four of these I had more surplus than from any other four colonies I had; and up to the time for final packing for the winter I had no trace of foul brood.

After all the bees had left these five hives I waited for a rainy day, removed the hives, and melted the combs.* This was the last of July. I think there was not one pound of honey in all the hives. It had all been converted into bees.

There are many advantages in this method of treatment; and, so far as my experience goes, no disadvantages.

1. No loss of brood or honey.
2. No chance to spread the disease.
3. Ease of operating (a box hive can be treated as easily as any).
4. Improving the stock, and working toward immunity.
- Automatic requeening.
6. Strong colonies ready for harvest.

Of course, more than one healthy colony could be used in this treatment; but I wanted to give it as severe a test as possible. It would seem as if bees from diseased colonies carry the disease with them when they leave the hive. In other words, if the Baldridge plan is not safe, then the hive through which five colonies had passed would show some sign of the disease before fall. It did not.

Pittsfield, Mass., Jan. 7.

REMOVING THE QUEEN AND TWO COMBS OF BROOD TO PREVENT SWARMING

BY A. C. GILBERT

Last year spring dwindling did not trouble our bees. They had a large amount of brood, but as they were mostly in air-spaced hives (chaff removed) none chilled during several weeks of cold weather. They built up into powerful colonies early, while other beekeepers around told of their bees dwindling.

Our bees were protected on the north by buildings, and on the west by a high fence. Had that something to do with it? As early in the season as the weather permits, all colonies are looked over in order to ascertain the strength and amount of stores. If any are found light in bees, some of the combs are removed, and the division-board moved up in accordance with the size of the colony. All needed stores are supplied, after which empty combs and combs of honey are added from time to time.

As swarming time comes, a number of the first swarms are hived on empty combs or foundation. If it is very early, and increase is desired, the swarm can be hived in

a new hive on the old stand and the old colony removed to a new location at once, or seven days later. This is a very common way, but all right at a certain time in the season. The right time in this locality is when the new colony will store well, as in the early part of the clover season. The old colony will be just right with a new queen laying for the last of the clover and bass-wood.

If no increase is desired we sometimes remove, for fourteen days, two combs of brood and some bees with the queen. If no cells were started at the time of removing the queen, removing the two combs once is all that will be required before returning the queen and brood. If two combs and a queen are set back of the division-board with a small piece of zinc on it the queen and brood can be returned with perfect safety to the queen on the fourteenth day.

MAKING STRONG COLONIES THAT SHOW SIGNS OF SWARMING DRAW OUT FOUNDATION FOR BAITS TO BE USED BY WEAKER COLONIES.

When very populous colonies show signs of swarming, shaken swarming can be practiced, which might save some confusion by preventing too many swarms coming out together.

I have often read how colonies not very populous store comb honey in the bait sections only, and leave the foundation untouched. I struck on a way to get foundation drawn for such colonies. During a time when the bees are gathering nectar rapidly, place a super of sections with foundation on top of the super or supers already on a very populous colony. In from 24 to 36 hours the foundation will be drawn out beautifully and white—far enough so that a moderate-sized colony will begin to store at once. I think there is a gain of one or more supers from such colonies some seasons. During the time the bees are drawing the foundation there seems to be no let-up in storing honey.

Honeoye Falls, N. Y.

PROTECTING BEES FROM INJURY WHEN SHAKING THEM FROM COMBS

BY M. G. DERVISHIAN

When shaking bees from combs with a sudden jerk on the entrance-board or on the ground, the bees are injured more or less, and become angry. To avoid this, and in order to save the queen from any injury, I make use of a soft quilt half an inch thick and about two feet square. I spread this before the entrance, and over it a soft nap-

kin extending very close to the entrance. The reason why I make use of the napkin is that often the light nectar is thrown out by the sudden jerk and falls on the napkin. The quilt is then saved from being soiled, as it can not be washed as easily as the napkin; and when the very young bees remain in heaps on the napkin I tilt it and shake then toward the entrance. In this way I help them to go into their hive very easily, so it takes only a few minutes to make all of the bees enter the hive. I shake the bees in the same manner as explained and illustrated on pages 19-21 in "A Year's Work in an Out-apiary," by Mr. G. M. Doolittle.

PROTECTING BEES FROM BEING CRUSHED BETWEEN THE WALL OF THE HIVE AND THE SIDE-BARS OF FRAMES.

The shape of my frames resembles that of the Hoffman, but they are only eight inches deep. For end spacing I make use of a small headless wire nail on the under side of the top-bar in place of the end-spacing staple used on the Hoffman frame.

To prevent the bees from being crushed or hurt between the side-bars and the wall of the hive I drive a small wire nail at the outside of the lower extremities of the side-bars of the frames. This nail furnishes a bee-space when lifting upward the first one or two frames from the hive. Of course, when one or two frames are removed the others are taken out by moving laterally. In this way no bees get hurt or killed, and so my pets do not hate me.

ATTRACTING NATURAL SWARMS BY THE SMELL OF ORANGE LEAVES.

When I see that the bees are swarming I cut from an orange or a lemon tree a small branch with a few leaves. I bruise some of these leaves so as greatly to diffuse the smell. The bees are very fond of this refreshing odor, and they go and cluster on the branch. Sometimes when the bees are not flying high in the air I put the lemon or orange leaves in an open hive in which I intend to keep them; and when I move the hive near, the swarm descends and takes possession.

Nicosia, Island of Cyprus.

DECIMAL SYSTEM OF HIVE NUMBERING

BY THOS. BOLTON

In your July and August issues of last year, different writers point out the mistake of numbering *hives*, and say that the *stand* or position is what should be numbered. This is a correct conclusion, and step No. 1 in advance. But they still seem to adhere to some affixing of numbers to the stand;

and this has so many drawbacks, and involves so much extra walking about to view the numbers, as well as a "fixing" of some kind to each position, that if we can devise a means to do away with these evils we shall have taken step No. 2 toward an ideal system and a big step, too, for the oft-times hurried apiary worker.

There is a simple plan whereby we may accomplish this, and upon which I have worked my home and out apiaries for the past 20 years or more. It begins with the arranging of the apiary in rows of ten stands, preferably at regular intervals, or it may be of ten groups of stands. We then place at the beginning of each row, *after the first*, a numbered board about 9 x 7 inches, painted white, with figures in black, and as large as convenient. These head-numbers, as we call them, are nailed to stakes about 42 or 48 inches high, and it is sufficient, we find, to place one at the head of every alternate row instead of one to each row. The first board will be (as stated) at the head or beginning of the second row, and fourth and sixth rows, and so on. As there are ten stands in the first (and every) row, it will be seen that the first stand in row 2 will be 11; in row 3 it will be 21; in row 4 it will be 31, and so on, each ten in advance of the preceding row. In actual practice we omit the unit 1, and so the head numbers above read 1, 2, 3, the operator mentally adding the requisite figure as he makes his record or gives his instructions to an assistant, indicating any particular colony. This required figure will be known by a simple glance along the row.

Let us suppose he is at the sixth stand in any row. A glance, as he straightens himself preparatory to moving on, shows that the head number is 1; consequently the hive is 16; or if the head number were 5, say, or 12, or 20, you simply place 6 beside it, and your hive is known, without any loss of time, as 56, 126, or 206, as the case may be. There is, therefore, no need of numbering every stand—no need to walk about to sight a figure possibly on the end of a hive that is furthest from you; and the veriest novice can be sent with certainty to any hive. Then, again, if one is at, say, stand 75, on either side are stands in neighboring rows that perforce are 65 or 85—no count needed. Compare the plan of alphabetical letters or other schemes with this decimal system of hive-numbering, and they are as a farm wagon to a motor car.

Lambenk, Victoria, Australia.

[This is very similar to the plan suggested by Arthur C. Miller, p. 665, Oct. 15, 1912.—Ed.]

Apiary of John Wallace, Grand Junction, Colo., where bees were poisoned by spray falling on clover under the trees.

SPRAY FALLING ON CLOVER KILLED BEES

BY WESLEY FOSTER

Early last fall I was called to the vicinity of Grand Junction to investigate the cause of so many colonies dying during the height of the season. I reached Grand Valley about the first of September. Mr. John Wallace, a fruit-grower and beekeeper, met me at the hotel and took me out to his place, a mile and a half east of Grand Junction. We passed the now abandoned Indian school, surrounding which is some of the typical seepage land of the western slope country. Alkali shows in many places, and the orchards have either died out or are dying.

Mr. Wallace had lost upward of one hundred colonies of bees, so that was the principal topic of conversation. The only thing that was very apparent was that the trouble was caused by spraying. But spraying has been done for years, and little trouble such as befell the bees had been experienced before.

A few points regarding the methods of spraying may not be amiss. Most of the fruit-growers are alert and up-to-date, and do not spray during full blooming time, although there are some blossoms that get the spray before the petals fall, as all trees do not bloom evenly. But from five to seven later sprays are applied; and the spray falling upon the clover, alfalfa, or other

blossoms beneath, would doubtless poison the bees. "Cover" cropping has been practiced more and more each year—alsike, red clover, alfalfa, and sweet clover being grown. The amount of cover crops in comparison to the fruit acreage is small, and this has led some to think that the spray could not cause the trouble.

Arsenate of lead is the spray material that has been used largely; but because of its expense a considerable number of fruit-growers have been trying arsenide of zinc. I understand the arsenide of zinc has not given the results secured from using arsenate of lead. The trouble from poisoning bees began about the same time as the use of arsenide of zinc, so that this seemed the cause in some minds.

The spray which fell on the clover poisoned some cattle and horses that were pastured in the orchards.

Some died and others recovered. Mr. Wallace had a cow that sickened and dried up, but she finally recovered. A flock of sheep pastured on the alfalfa in the orchard shown above were not affected by the poison on the leaves at all. The sheep are shown back of the row of hives. These colonies were purchased to help make up the losses caused by the spraying. Mr. Wallace told me early in March this year that he had only about 35 colonies left, so his losses have been considerably above one hundred colonies.

Partial view of P. Mereconchini's "Virginia" apiary, located near Manzanillo, Cuba.

The losses were confined to the fruit districts. As soon as I got two miles away from any orchards no more losses were found among the apiaries, and good crops and plenty of increase was the rule.

Boulder, Col.

AN AMERICAN APIARY IN CUBA

BY P. MERCONCHINI

I take pleasure in sending a partial view of my little beeyard, located about 300 yards from the last house in this city, and near to the Cuba Railroad water-tank. I am now running 50 colonies, as I have no time to attend to more. The bees are all Italians, of an American strain.

In this vicinity there are about 2500 colonies. My assistants are my two boys—Rodrigo, 11 years old, and Luis Maria, eight. They are good assistants but better honeyeaters.

Manzanillo, Cuba.

THE LATEST FORM OF THE FERGUSON UNCAPPING MACHINE

A Light Model that Can be Pushed Down Over the Top-bar while the Frame is Still in the Super

BY L. R. FERGUSON

Since the appearance of the article, July, 1909, describing my uncapper, I have been devoting most of my spare time to develop-

ing a machine especially adapted to use with the Hoffman frame. As the character of the end-bars is such that the frames can not be pushed through the machine endwise, as in the former machine, it occurred to me that there would be a decided advantage in making the machine light enough to be easily handled and pushed down over the frames as they hang in the super, and then leaving them in the super to drip, thus eliminating one handling.

To obtain the best results, the capping tank should be set low down and provided with slides or rails so arranged that the supers as taken from the hives can be put on at one end, and easily slid along toward the extractor at the other end after the combs are uncapped. In this way the handling or moving of the combs is all done by the superful instead of singly, thus saving a great deal of time. When the supers are set on the slides the frame next to the operator should be removed to give room for the machine to enter the supers. These removed frames should be put in another super; and, when the right number have accumulated, put on the slides with the others.

In the act of uncapping, the operator grasps the handles of the machine and enters the points of the end plates, one end at a time, just inside the end-bars of the frame as shown in Fig. 1; then he pushes the machine straight down over the frame, removing the cappings from both sides of the

comb, the cappings dropping into the tank below.

If it is desired to leave the comb in the super the machine is then withdrawn, and the operation repeated on the other combs in their respective turn; but if it is desired to remove the comb, the operator grasps the handles at the center, which causes a couple of dogs, or catches, to engage the top-bar of the frame, and the comb is withdrawn with the machine as shown in Fig. 2, and may be deposited in any desired place; but in either case it is not necessary for the operator to touch with his hands a single frame until they are lifted to put in the extractor.

Nearly every one to whom I mention this feature of leaving the combs in the super after uncapping doubts there being any advantage in it; but let us see. After the machine is pushed down over the comb it is nearly as quick and easy to withdraw the comb as to leave it; but after it is withdrawn it takes fully as much time to swing the comb over to any kind of rack, deposit and release the comb, and bring the machine back to position as it would take to uncap another comb; or, in other words, two combs can be uncapped and left in the super in the time required to uncup one and deposit it in some other place, or the simple expedient of leaving them in the super will double the capacity of the machine.

Considering the great variation in styles of frames, and in the degree of care or carelessness bestowed on the building or securing of combs, I believe I am safe in saying that there will never be built a practical machine which will work equally well with all makes or styles of frames, so it follows that the machine which will work well with the class of frames in most general use will be the most practical machine, and that is just what I believe I have produced. But, as with all other improvements, it will be necessary for the beekeeper to meet it part way by making such changes in his management and equipment as will favor the successful use of the machine, and this means a little extra care to secure reasonably straight combs, and wide enough spacing to insure as much as a $\frac{1}{8}$ -inch bulge on each

P. Merconchini's two boys who will be extensive beekeepers some day.

side of the top-bar. This will insure a gain or saving of two frames in ten, or 20 per cent in frame equipment, and anywhere from 50 to 75 per cent in the cost of uncapping; and this saving surely makes it worth while to take some extra pains in securing the right kind of combs.

Mr. J. J. Wilder, of Cordele, Ga., who has used two of my experimental machines, writes me in part as follows regarding his impressions of the last one:

Your 1912 model uncapper came to hand in due time, and we set it to work at once, and have done a lot of uncapping with it. I uncapped lots of old tough combs containing thick sticky honey, and we are pleased with it, with only one exception. We can't get close enough to the top-bar with it. It leaves from two to five rows of cells near the top-bar on straight smooth combs built out just even with the top-bar; but it runs over them nicely when they are bulged a little. * * *

This is the only suggestion I have to offer, for it certainly uncaps the honey in shallow and deep frames except a few rows of cells at the top, and this is so easily overcome that a suggestion is not

P. Merconchini and his extracting force ready for work.

FIG. 1.—Latest form of the Ferguson uncapping machine. Entering the points of the knives at one end of the frame.

necessary. * * * We must have one of our own next season. It works well and fast, and leaves the combs in ideal shape. * * * I did not sharpen the knives while here. I thought several times I would; but upon examination I found them as keen as they were when they arrived. * * *

We put up in all, while your machine was here, 24,000 lbs., and the uncapper was run over every comb that it would uncap, even a portion of the combs, so you can tell about the amount of service it gave us.

The above amount refers to "bulk comb," so the amount uncapped would be the amount necessary to put up that quantity of "bulk comb."

Another beekeeper who had the machine wrote me in part as follows, and his criticisms are those most frequently raised:

There are many thin combs with irregular surfaces that the machine will not get at. Another thing, one could not use the machine on combs containing any sealed brood.

If I understand the above, it means extracting combs thinner than those of sealed brood; and I am free to admit that satisfactory results could not be obtained under such conditions. The facts of the case are that neither of these men had made any special effort to secure thick combs for use

with the machine; and Mr. Wilder especially, I understand, uses eight frames in an eight-frame super, securing a slight increase in thickness by leaving out the division-board, so it is easily seen that the results are not such as would be obtained where the proper preparation had been made.

The one element of uncertainty is whether or not beekeepers can and will produce combs that bulge $\frac{1}{8}$ inch or more beyond the top-bar for about two inches down. The form of the knives will not admit of their cutting in abruptly under the top-bar; but they must pass straight down for about $1\frac{1}{2}$ or 2 inches, or until their heels have passed the top-bar, and then they are automatically forced in toward each other until they are just far enough apart to pass the bottom-bar so they will take care of any ordinary irregularities in the central and lower parts of the combs where they are most apt to occur. This style of knife has now been used long enough to prove beyond doubt that it is successful and practical.

I will admit that bulged comb can not be secured without some special care; but I do know that I can produce such combs, and uncap them easily, at the rate of ten frames per minute; and a speed of twelve to fifteen frames per minute would not be hard to attain, I am sure, after one becomes somewhat expert in handling the machine.

I find that eight frames in a ten-frame super are about right for good results; and after the combs have once been built out and uncapped, each later filling and capping is bound to build them out enough to insure a good clean job of uncapping.

Harvey, Ill.

BEEKEEPING IN THE SEMI-ARID REGIONS OF OKLAHOMA, KANSAS, AND NEBRASKA

How Sweet Clover is Being Developed

BY E. R. ROOT

Business and other reasons called me into Oklahoma and Kansas along the latter part of January; and in our Feb. 15th issue I promised to write up the beekeeping conditions in those States, saying I thought there were exceptional opportunities for the development of new bee territory alongside of those immense acreages of alfalfa in the valleys. In accordance with the promise then made, I present a few observations, with particular reference to Oklahoma, where I spent most of my time, in the vicinity of Stillwater. Here resides Mr. F. W. Van de Mark, Secretary of the Oklahoma Beekeepers' Association, and Prof. San-

FIG. 2.—Withdrawing the uncapped frame from the super.

born, Entomologist at the Oklahoma Agricultural College.

I do not know of any State in the Union that offers greater promises in an industrial way than Oklahoma. Its cities and towns are growing by leaps and bounds. Immense beds of asphalt and coal have been discovered there. Gas and oil wells are being put down in many places throughout the State. Agriculture is developing at a rapid rate, and beekeeping is one of the industries that has a future. The trains are loaded with home-seekers and butchers and bakers and candlestick-makers, suckers and fakirs rushing to the land of gold and sunshine. I said "suckers." I do not know any other term that adequately expresses the large class of people who buy land out in that western country, some of which is worthless, and buy with their eyes shut.

Let me say as I have said concerning Florida and every other new State that is being rapidly developed. There are fakirs and suckers by the hundreds; but having said this, there are some excellent opportunities for men of brain and caution to invest in land that will bring some splendid returns. But there are other lands that will take a lifetime before they will bring the price that has been paid for them. Not until the population of Oklahoma becomes congested and elbows touch will this land not so good be developed. In this connection let me say that there is a great deal of

difference in the productiveness of land in Oklahoma and Kansas. Some of it will yield immense crops, and some of it poor crops. Pictures showing some fabulous yields, accompanied with photos or half-tone engravings, are sent out broadcast over the country. They catch the eye of the get-rich-quick fellows, who, of course, swallow the bait, hook, bob, and sinker. They leave a good job in the East, sell out, and move their families. There are hundreds of such families who have been robbed of their hard-earned money. It makes one's heart bleed to see them stranded on poor or worthless land, and no money to go elsewhere. The land shark got it all. And while GLEANINGS is willing to show that there are splendid opportunities in some of this western country, it also enjoins caution. Do not take the statement of the man who has the land for sale. Spend a little time in the country, and gather all the information you can. There are thousands of honest men who will tell you the truth if you will take pains to look for it. This is not only true of Florida and Oklahoma, but other States in the Union.

Now, then, how about beekeeping in Oklahoma, and I might also class with it Kansas, for the climate and soil of the two States are much the same? Alfalfa is being grown in both States as it never was before. The Kansas farmer once supposed that the only thing he could raise was corn;

One of J. J. Wilder's apiaries, made up of Caucasian and also Italian colonies, run for the purpose of proving which are superior.

but he is now discovering that alfalfa will grow along the creeks and rivers—that is to say, in the valleys where it will yield immense crops, of sometimes three or four cuttings in a season. What is more, this semi-arid country does not have to depend on irrigation, which sometimes fails further west. Its own creeks and rivers water the valleys on both sides, and the dwellers in these valleys are becoming prosperous, and largely on account of alfalfa which enables them to produce meat. With the present

a home-seeker's ticket with the privilege of stopping off, taking in the territory of both Oklahoma and Kansas. Let him stop a few days at a number of hotels. Let him inquire carefully where alfalfa is grown. Go over the whole territory, and then after returning home let him fix on some location, and make a start in bees where no one else is located.

Another promising thing in both States is that farmers are beginning to find that sweet clover will grow on the uplands, and furnish a fine hay and pasturage for sheep,

hogs, and cattle. In fact, sweet clover will grow on these uplands where it was supposed that nothing but prairie grass would thrive. But sweet-clover pasture I am told will support a much larger number of hogs and sheep than even alfalfa, because it can be cropped down closer without killing. There is bound to be immense development in this legume, in these semi-arid regions, in the next ten or fifteen years; and the early bird if he looks before he leaps will be the one that gets the worm.

In Oklahoma we find that cotton can be

J. J. Wilder, the late Mr. Herlong, and Mr. English.

L. E. Thoen's apiary in apple-blossom time.

grown in a large portion of the State; and cotton is an important honey-plant. It works in very nicely with alfalfa; and while the honey is not the best, it is very much better in color and flavor than has been commonly supposed. Professor Sanborn, before mentioned, has discovered that cotton yields not only honey but honey-dew. But I will not say more about this, because he has made some discoveries that he will make public later on. Permit me to say that Professor Sanborn, Entomologist of the State, is one of the most progressive men in his profession. He is a beekeeper by birth and training, and an entomologist. He is doing every thing he can to foster the general bee business within the State. He has a small State apiary for demonstration purposes, and apiculture is one of the courses taught at the institution.

THE INDIAN QUESTION.

Once or twice at the hotels I ventured to talk about the Indian question in Oklahoma. Finally one man across the table, observing that I was a tenderfoot, said to me, "Young man" (I am nearly 51), "the less you say about the Indian question, the better for you." Then dropping his voice down to a whisper that I could just catch, added, "It is a *redhot* question, stranger—much hotter than the negro question in the South. Believe me, no matter which side you take, you will get into hot water."

I put out several "feelers," and found that he was right. I may say, however, at

this distance, that the Indians own valuable lands in the western part of Oklahoma—lands that have immense deposits of asphalt and coal. Some of the Indians are immensely wealthy. They have no conception of the value of a dollar. The white man is fleecing them right and left with all kinds of devices. Uncle Sam's agents are trying to protect them, and it was hinted that *some* of them *might* be open to bribes. Certain it is, the Indians are losing their lands, and the white men are getting possession. From the standpoint of industrial development this is, no doubt, a good thing; but from the standpoint of equity and right it is wrong—that is, providing the white man cheats his copper-skinned brother out of his just rights.

Why is the Indian question a "hot one?" Because it is mixed up in politics, both State and national. Honest men have different opinions, and some men not so honest are biased by selfish schemes.

There will doubtless be considerable inquiry concerning Oklahoma and Kansas, and so I take pleasure in referring to two men who are not interested in the sale of land who may be able to give some information; but perhaps they will not thank me for giving them this kind of publicity. However, I will take the risk: F. W. Van de Mark, of Stillwater, Oklahoma, and Carl F. Buck, of Augusta, Kansas.

Shortly after the Feb. 15th issue of GLEANINGS was out, I received a couple of

Scholl's handy apiary wagon.

letters from subscribers in Kansas, who, fearing I would make too rosy a description of the semi-arid West, wrote, suggesting caution; but I am happy to state that the article above was written before the letters came, and so I think no one will accuse me of booming new territory if he reads all I have written, especially what I have said above. There are good and bad lands, and there are sharks and honest men. The wise man will use his own judgment as he thinks best. Here are the letters:

In GLEANINGS for Feb. 15, page 106, you refer to alfalfa yielding honey in Kansas. This is true of a good many localities in the State, but not all. In the country immediately surrounding Topeka it is only occasionally that bees will work on alfalfa bloom.

At our State beekeepers' convention this year the honey reports ran anywhere from ten to one hundred pounds per colony. Most of the heavy yields came from localities where alfalfa is grown for seed. It seems to be a fact that, where seed-growing is profitable, conditions are such that the plant secretes considerable nectar.

A man who has a favorable alfalfa location in one of our western river bottoms said that, in his locality, alfalfa could be depended upon to yield nearly all season if it was on land where water could be reached at a depth of ten feet or less, while alfalfa on higher ground could be depended upon to yield only after a refreshing rain.

Alfalfa is particularly susceptible to atmospheric conditions; and any one not familiar with the peculiarities of this plant would be apt to go astray.

North Topeka, Kan., Feb. 24. A. V. SMALL.

The following is a private note to the editor, not for publication, but as it states the "other side" I give it here without the name and address.

I believe it wise to go very slow about advertising Kansas as being great for bees. There is no class so easily stampeded as beekeepers, on account of being able to move what they have. The sight of alfalfa does not imply bee locations by any means. I have alfalfa on my farm. My neighbor has fields 18 years old; but I never saw a bee on it, nor have I even seen a pound of alfalfa honey produced in the eastern part of Kansas, and I have lived here 35 years.

Where alfalfa is grown for hay it is not much of a success for bees. Where irrigated, which is very little in Kansas, and where grown for seed, there is not much of any flora to build up with; and then in these last-mentioned districts, the winds!

Sunflowers and cottonwood along the streams, and wheat and corn districts are nothing to start a stampede on. Kansas is a great State agriculturally, but a mighty poor place for people of moderate means to make a start, as our farms are large and the land valuable. I am of the opinion that a matter of location is one to approach with care. I am of the opinion, also, that any thing of extensive transitory or non-resident beekeeping would be a flat failure in Kansas or Oklahoma; besides, such beekeeping would be conducive to disease.

SUBSCRIBER.

I know of places in your State where alfalfa does yield honey.—E. R. Root.

WINTER CASES MADE OF OLD BOXES

BY L. E. THOEN

I am sending a photograph showing part of my apiary on the 28th of April, 1910. Most of the hives, as shown, still had the winter cases on. Those cases were not very sightly, as they were made of all kinds of lumber. There was a space of two or three inches between the hive and the case on all sides except the front, and also a few inches on top, to be filled with packing, a tight cover completing the case. The bees wintered as well with these boxes around the hives as they do in the more expensive outside cases that I am using at present, which are built of inch lumber, with a telescope gable top of the same material, the latter covered with galvanized iron acting as a roof.

Spearfish, S. D.

MORE ABOUT CAUCASIAN BEES

BY J. J. WILDER

Owing to the great variation in conditions which season and location bring about in the beekeeping industry it is possible to advocate too strongly some particular feature, such as stock, methods, or conveniences. It may be that I have advocated Caucasian bees too strongly; yet, on the other hand, possibly not enough has been said about them in our bee publications. Many have tried them, and very few have condemned them. In the majority of cases where they have been thoroughly tested they have been found superior to any other race of bees. In some instances they have even revolutionized beekeeping, so they must have a high commercial value, and must be here to stay.

Each season for a number of years, except this spring, I have been rearing and selling queens of this race of bees. This season I could have sold more than 1000 queens, and most of these to the same old customers; but since I have decided to go into very extensive beekeeping I will not offer any more queens for sale, but will use all I can possibly raise in my own apiaries. Since they have met with the approval of so many, are fast coming to their own, and have so completely changed beekeeping for the better in my own experience, I can not withhold my pen. I have tested these bees very extensively, and from time to time I have made known what I have found about them, good or bad.

I want to emphasize again two of their superior qualities—viz., that for honey-gathering and of rearing large quantities of

bees throughout the season. I will do this through the testimony of another beekeeper whose experience exactly coincides with mine.

Mr. J. J. Wilder:—How are your Caucasian bees holding up? Are they still leading the Italians in real business? Mine have, and in this location of no honey they average me 50 lbs. surplus while my neighbor's eight colonies of Italians stored no surplus at all, and, besides, dwindled to only four colonies.

Another beekeeper near by had 108 colonies of Italians, and they decreased to 47, and he had to resort to feeding nearly all summer. It is plain that the Caucasians gathered honey from some source while these two lots of Italians were perishing.

Then, too, they kept their brood-nest chock full of brood all through the season, and I doubled the number of colonies and got an extra set of combs built in the supers. It would have done you good to see the great stream of bees going and coming from each hive while the honey-flow lasted.

I imported some queens this season direct from the Caucasus, and the workers are uniform in color, and not a trace of yellow about them, nor are they dark in color, but a dull gray, and are as striped as zebras. They are hustlers too. I am going to make a specialty of Caucasians, for I believe that they are the coming race of bees. My friends in the North say that they winter well and do not dwindle in the spring as do the Italians or their crosses; and, besides, they are gentler, and will stand more abuse and neglect. I have always found them good, even under the most adverse conditions.

CHARLES W. QUINN.

Houston Heights, Texas, Nov. 11.

One of the illustrations is a snapshot of our first Caucasian yard along with some other races and strains of bees which we had under test side by side. The result of the test was that the Caucasians had more to their credit for our purpose.

The other view shows the corner of the same apiary and three beekeepers who had just finished examining all of the colonies in the yard for the purpose of ascertaining which strain of bees was giving the best results. The Caucasians scored the highest number of merits.

The man standing on the right is Mr. English; and the man in the middle is the late Mr. Herlong, both extensive beekeepers of Florida who also adopted the Caucasian bees and found them superior. The writer is standing at the left.

Cordele, Ga.

A MOST HANDY APIARY WAGON

BY LOUIS SCHOLL

After having used a handy wagon that is well suited for almost all purposes in an apiary, it is hard to understand how a beekeeper can really get along with any other kind of wagon with which to do his hauling. Planning to haul bees or hives, supers, or cans, on a farm wagon or with only a small spring wagon, caused many a hes-

itation before the hauling was finally done. With our big handy wagon, all there is to do is to hitch up to it and then load and do the hauling, no matter where and when.

The group of pictures shows a full platform spring wagon with a capacity of from 2000 to 3000 pounds at a load. The bed is entirely flat, like that of a large float, 14 feet long and 48 inches wide. It is provided with removable stakes which can be put on in a few minutes. The wagon runs so easily that there is hardly any jarring of the load, and it is not necessary to do any tying to keep the load from falling off. This makes the wagon especially well adapted for hauling bees, and also for hauling large loads of supers with the foundation already in the frames. The bed is long enough to accommodate two rows of ten-frame hives, making 20 in a tier. A double-deck load of forty colonies can be hauled with ease with a team of two animals, and the entire load hauled on a trot on good roads. This enables one to make quick moves of an entire apiary in short order and without the usual disagreeable troubles about packing and joggling with unsuited wagons. All that is necessary in the case of moving bees is to set the hives on, placing them back to back, with the entrances out, preferably, so that these can be watched and be easily accessible in case of leaks. It is very easy to unload from such a wagon also.

For hauling our bulk comb honey from the yards, this wagon has proven very valuable. In the pictures the wagon is shown right beside the apiary fence in two places, with the wagon-bed entirely empty in one case and a wagon-cover on another. The supers are loaded right over the fence on to the wagon from the apiary as soon as these are taken off the hives and freed of bees. By loading them three tiers high, 60 supers are loaded on, making a load of about 2400 pounds. The whole is covered over with the wagon cover or sheet as soon as the honey is loaded on, and tied at each end as shown in the two lower pictures. In the two upper pictures the unloading is shown right from the wagon into the honey-house. In one the large screen-door is wide open; but in the other only a small opening is left (because of robbers), through which the honey is passed to a man inside.

In another picture the wagon is shown with the stakes in place for hauling covers and bottoms and other bulky things without having to tie any thing with long ropes. By going from one yard to another, any thing that is needed at any particular one can be taken out as needed, without useless untying of ropes, etc.

It will be noticed in all the above pictures

that the horses are not attached to the wagon, except in one instance. In this one the driver has just arrived at an apiary and is unhitching to take the team aside to a safe hitching-place. Always do this, since there is no telling when the bees might sting the team and cause considerable trouble and disaster. Especially should this be watched in time when bees are robbing badly.

To get the load away from the apiary when bees are robbing, and it is not safe to hitch direct to the wagon, a long stout rope is used to which the horses are hitched. This has a large hook at the other end, which is hooked to the end of the wagon-tongue, and the load is pulled to a safe distance from the apiary, where the team is then hitched to the wagon.

New Braunfels, Texas.

SHIPPING FRAGILE ARTICLES

Some Advice from One who has had Experience

BY JAY W. GEE

Inasmuch as the writer's first knowledge of GLEANINGS, and a subsequent interest in the bee industry, was a direct result of a broken case of bee supplies it may not be amiss to repay the debt to the fraternity by giving my experience in the transportation business, covering about ten years. Some years ago I was agent for a railway at a point where a heavy transfer business was done, from five to twenty cars being handled daily. There was a white foreman who checked the freight, and had the general supervision of the platform; but all the trucking and actual handling of the shipments was done by a gang of negroes, all of whom were illiterate. It was not possible for me to be on the platform every day; but I would make an inspection as often as possible. One day while looking over the situation I found quite a pile of curiously sawed little sticks lying by themselves around a post, with no case near, no mark on any of them, and no possible way to connect the sticks or make any thing out of them.

I called one of the boys, "Tom, what's this you have here?"

"Fo' God, Cap, I dunno. Yistiddy when us wuz unloadin' the St. Looie cah, Pete, he dun drap a box frum the flatfom an hit bust wide open, an all them sticks come out. Us wuz goin' to put 'em back, but the boss lowed 'twont no use, fur some feller had jess put em in dat air box fur trash to get rid of, an Pete say dey sho would make good kindlin', an' dun bunn bout haff ob 'em dis mawnin'."

There was a little magazine lying near which I put in my pocket for future reference; for I am like the ancient Athenians in one respect at least—always on the alert to learn some new thing. The little sticks found their way to the stove; and a few months later, after I had perused the little magazine—GLEANINGS—and some other bee literature, the mystery of the little sticks was solved. The railway company had unintentionally used a nice lot of frames and other fixtures for stove kindling, and in due course paid the claim, I suppose. The shipment went beyond me for final delivery, so I can not say as to that. If there is a moral to this particular incident, I suppose it is that the various railways of the country should have all their employees take a course in bee culture, and so reduce the amount of their annual claim budget by avoiding a recurrence of such mistakes in the future.

Now, you old-time beekeepers need not be amazed at such gross ignorance outside of your ranks. The biggest part of the losses that the railroads and the public sustain is caused by the ignorance of one party of the methods and working tools and parts of the other. This is not any disparagement to any one, either, for in one short life it is impossible to master all the details of every calling, trade, or profession.

The purpose of this article is not to urge the use of any system in behalf of such system by reason of any interest of mine in it; but it is purely a matter of information that may be of help to some of the many readers of GLEANINGS.

Before I began working for the railroad I spent two years in a postoffice of the third class on the main line of one of the trans-continental railroads in Oklahoma. The biggest part of our mail was put off from the through trains. There was a grade just beyond our little town; and in order that the heavy trains might cross it without stalling they had to go at full speed by the station. When the sacks were kicked from the mail-car they would sometimes fly thirty or more feet away, and it was not safe to be in their path. It was a sickening sight, sometimes, to go through these sacks and to see the condition the contents were in. I remember one Christmas morning in particular, when the sacks were dumped on our work-table, there was not a single package intact, the whole being an indiscriminate mass of doll limbs, scalps, dresses, tin soldiers, wrecked cars, and the like. Whether the practice yet obtains, I am unable to say. Of late I have received several fragile packages by mail from long distances without damage; but the outer packing had not been

crushed. I have noticed several reports in the papers since the parcel post has been in operation, where eggs have been sent through the post and have been broken.

The cause is not hard to find. The post-office officials have not yet made sufficient arrangements for the handling of this business; and until the Department is fully prepared to take care of all kinds of business it would be better for the public to use a safer method than the open mail for fragile matter. To label a package "With Care," or "This Side Up," is absolutely useless, as few ever see it, and fewer pay any attention to it when they do see it. A swift glance at the address, and flop it goes into the sack it belongs in, whether a foot away or ten. Registered matter receives better treatment, being handled personally from one clerk to another. In a few years, when the express business is owned by the government or supplanted by parcel post, all parcels will be handled with the care that they deserve, and that they now get from the private express companies.

Handling fragile matter by freight, whether by carload or less, is still more unsatisfactory. Of late years the railroads have been burning their candle at both ends—through no intent of their own, be it said, but because it has been forced upon them by federal and State laws. Rates have been reduced, and no prospect of any advance, while every item of railway operation has steadily advanced in cost, especially material and labor; consequently every manager, every superintendent, and every boss of every kind, to hold his job has to exert eternal caution to keep expenses down. The usual devices are to cut labor, hours, materials, and improvements. Where special knowledge is not required, the very cheapest labor is used. In the South that means negroes; in the Southwest, Mexicans; in the East, Italians or other foreigners. Now, what is the result when your case of honey is marked "Glass"? The inscription is never read; and if it should by accident be read it receives absolutely no attention. A car holds just so much. In time of a car famine every available piece of freight is put in, and seldom with regard to any consideration except to fill space. Of late some of the systems have been making an effort to remedy the careless loading of freight in an effort to cut down the enormous amounts being paid for claims, but the progress is slow.

But suppose that the case is properly loaded, or that there is a carload shipment. Dynamite used to be handled indiscriminately with other freight, and the loss of life was so great that the federal government

had to step in and regulate it, with the result that last year there was not a single death from this cause in the whole United States, so a federal inspector recently told me. Every case of dynamite or other explosive now has a big red label on it. It is braced in the car so that it can not move, even if the car is wrecked and turns over. Nothing that can easily catch fire or explode is allowed in the same car. Furthermore, the car is inspected, large tags are put on every side, and the car placed in the safest part of the train.

Now, if all this can be done for dynamite, why can not something similar be done for honey? It is worth taking up in the next national convention. Suppose that a certain color, whether painted on or pasted it makes little difference, be used on the tops of all honey-packages, a regular system of bracing be agreed upon, and, in the case of carloads, placards be put on the outside of the car to let switching crews know the fragile nature of the lading. Too much should not be asked of the roads, as a raise in rates would follow; and whatever is agreed upon should be with the understanding that the shipper be required to furnish every thing, and perform all the extra labor incident thereto. I add this because it will be useless to ask any railway management at this time for any thing that will add any expense to their burdens, which are already too heavy.

To be continued.

Drones from Drone-layers; Are They any Good?

I have some fine Golden queens that I raised from a breeding queen last fall, and they did not mate. Now they are laying drone eggs. Will those drones reared in drone comb be all right to breed queens to? Kendallville, Ind., March 31. O. P. ELDRIDGE.

[Drones from drone-laying queens are not generally regarded as the equal of drones reared from ordinary normal queens. A good many doubt whether they have any potency at all; but it is generally believed that they are better than no drones. If a virgin queen were fertilized by one of these drones the probabilities are that the result of that mating would not last as long as though she had been mated with a drone from a normal queen.]

Drones from queens that have formerly laid worker eggs, and yet later lay only drone eggs, are good. We have used them extensively, and have reason to believe they are all right.

However, we are frank to say to you that no scientific experiments have thus far been conducted to prove whether drones from drone-laying queens are the equal of those from the ordinary average queen. Possibly the Bureau of Entomology, Washington, D. C., may find its way clear to give this matter investigation. Microscopic examination of the seminal sacs of the drones from drone-laying queens and drones from the ordinary normal queen would doubtless show whether the former had as many spermatozoa as would be found in the other drone. Ed.]

Heads of Grain from Different Fields

Extracting Close and Feeding; the Price of Beeyard Labor

With our plan of producing extracted honey, the bees and brood are kept together throughout the season. At the last manipulation the queen with a small patch of brood is put into the lower story with an excluder over it; and all the surplus chambers, filled with the brood and empty combs, are put on over the excluder. With this plan the brood-chamber never becomes clogged with honey; and the question is, What is the best method to employ in getting winter stores to a colony? Whenever we believe the last honey gathered from basswood to be ripe, we begin the work of extracting. When the supers are taken off, the brood-chambers have all the way from a very little to about twenty pounds of honey in them. In this locality the flows following the basswood run barely supply the daily consumption of a colony.

Our object in writing is to learn if our method of carrying a colony over into the next season, to a time when the bees can gather what they consume every day, is as practical and efficient as any that could be employed, so far as feeding is concerned. By exchanging combs with the bees we aim to supply our lightest colonies with at least ten pounds of honey at the time of extracting, and two full combs of honey are set aside for next spring's feeding. Early in September we begin the work of feeding up for winter, with a feed made up of the following proportions: boiling water, 1 part; cane sugar, 2 parts; 1-3 as much honey as water. We are well equipped with large feeders that hold more than any colony will ever need for winter stores. The wagon, used for transporting the feeding outfit, is arranged to carry 100 feeders, the necessary sugar, honey, and a water-heater of 160-gallon capacity. The capacity of the heater allows the heating of sufficient water to make feed enough for an apiary, and still leave room for a rack which can be set at varying heights from the bottom of the boiler, and on which the five-gallon cans containing the honey for feeding can be set and heated. By means of a large gate, boiling water is drawn from the heater into a large mixing-tank, and the honey and sugar added. The feed from the mixing-tank is also drawn, by means of a large gate, into large graduated pails having large snouts to facilitate pouring the feed. The water is put on to heat, and is ready for use by the time the feeders are on the hives; and, with two men working with a vim, a large number of colonies can be fed up in short time.

Colonies run for extracted honey are always in more or less need of winter stores; and to supply this want by giving them combs of honey in the fall seems impractical to us, therefore we adopted the plan outlined above. Then, too, we can buy sugar of excellent quality for feeding purposes at \$1.50 below retail prices. We use powdered cane sugar that is swept up on the floors of the sugar-mills. This sugar is free from dirt, but contains about one per cent of starch.

We are great believers in an abundance of stores; and your candid opinion, on our method of supplying winter and spring stores, will be cheerfully received. We could have given you a great deal of detail, but did not think it necessary. This will be the first season when we shall have to employ outside help; and as we are not posted on the wages beekeepers have to pay, we should like to ask you in regard to this also. What wages could an intelligent, trustworthy man who works steadily with the speed of an average person, and who can do very satisfactory work of all kinds in the workshop, and carry out any kind of orders in the beeyard, but who has not had sufficient training to take the initiative, be paid

per month, including good home, board, and washing, in a locality where farm hands receive \$30.00 and dairymen from \$35.00 to \$40.00 per month? Again, how much more per month can a beekeeper demand than a farm hand, other things being equal?

E. L. HOFMANN.

Janesville, Minn., March 25, 1913.

[The plan outlined seems to be correct so far as we can see. There are only two ways by which you can supply a colony with stores after extracting. One is to equalize stores by changing combs, and the other is to feed. But in your particular case it would be more practicable to extract close and then feed.]

Your method of feeding seems to be all right; but did you ever try the plan of making up the feed at home, and pouring it into 60-lb. square cans? A wagon is necessary to carry your melting-apparatus, sugar, and honey. You can carry all the syrup you need in square cans unless the yard is very large. By so doing you will need to carry only one-third more of the actual bulk in water. It sometimes transpires that it is inconvenient to get water at an outyard. If there is a dearth of honey it is impracticable to make the feed at the outyard, any way. However, we employ both methods, making the syrup at the yard; but more often we find it convenient to carry the syrup, and then it can be given to the colonies while hot.

The question of beeyard labor depends somewhat in outside labor, as you suggest. A competent man in the yard, one capable of going ahead alone, who knows how to put colonies in condition for a harvest as well as extracting and taking off comb honey, will command about double the price of ordinary labor. In some cases you may have to pay three times as much. A thoroughly competent man who can manage a series of yards so as to make money for his employer is hard to find, for the reason that, if he can earn money for the other fellow, he will prefer to be his own boss, and make the profit for himself.—ED.]

Uniting by the Alexander Plan Not Always a Success; Mating Queens from an Upper Story Generally a Failure

Is the Alexander plan of placing weak colonies over strong ones in the spring for the purpose of building up, a recognized success? Is anybody getting virgin queens mated in the second story over a queen-excluder? With me, both schemes are failures. Last summer I got lots of queens hatched in the upper story (over queen-excluders), but not one fertilized. In less than a week they disappeared.

This spring I put weak colonies over strong ones—i. e., Alexander's plan. Four days later I found queens of weak colonies all right, with a big force of bees. Two weeks later I found no eggs, no unsealed brood, no queen, except in one instance, where the queen of a weak colony was doing fine work; but the queen below the excluder had been killed.

Dixon, Cal., March 17.

J. T. BOWEN.

[The Alexander plan of uniting is not a success in the hands of every one. Some have succeeded very nicely with it, while others have met with failure. In some instances, at least, this failure is due to the fact that the directions given by Mr. Alexander have not been strictly followed. For example, he specifies that the two lots of bees—the weak and the strong colonies—should be put together, one on top of the other, very gently, so as not to disturb them. If too much smoke is used, or if the bees are disturbed, the queen in the upper hive will be destroyed. It is also very important to have a little brood in the upper story. If the nucleus is so weak

that it has only a few bees and the queen with no brood, the plan can not be made to work unless another frame of brood and bees is added to it. For full particulars on this plan of uniting see "Uniting," in our A B C and X Y Z of Bee Culture.

The plan of having virgin queens mated from the upper story of a strong colony generally results in failure. It sometimes works, however, during a light honey-flow. Even Mr. Doolittle himself does not advocate it now except under certain conditions. In any case the average beginner will succeed very much better by having his virgins placed in separate hives by themselves.—Ed.]

How to Know Honey-dew

Some are inquiring how to know honey-dew. If honey-dew is heated, there will be a scum about two inches thick. Skim this off and continue heating, and it will keep on throwing up froth indefinitely. If boiled, I fancy it will all go to froth.

If bees can have a flight once a month they will winter on honey-dew. When one-third of my bees died with it in the cellar, a few years ago, I uncapped the combs in the spring and gave them to the bees, and they built up finely on the "bug-juice." It is dangerous only when bees can not have a flight. If any beekeepers find that their hives contain honey-dew, and they are in the cellar I would advise them to carry the bees out the first day they can fly, and again in not more than one month's time.

Islington, Ont.

J. D. EVANS.

[We might suggest that there is some honey that will throw up froth after boiling, as well as honey-dew. We do not, therefore, believe that the rule suggested by our correspondent is infallible. The best test is the one of taste and color. While there are some honey-dews of fair quality, the most of them are very inferior, not to say nauseating, having a dark color, or purplish black. Nearly all honey-dew honeys have a sort of flavor that is common to all, although there is a honey-dew from Hawaii that does not taste like the American article; it reminds one more of New Orleans molasses. Chemically, however, it has the same qualities as the American product.

It may be true that bees can be wintered on honey-dew if they can have a flight once a month; but sometimes a winter will come when they can not have a flight for three months. For that reason we strongly advise extracting all honey-dew and feeding sugar syrup in the fall, for all localities north, we will say, of the Ohio River.—Ed.]

Best Time of Season to Requeen

I notice reports from different sections, of bees using up stores in early breeding. Not so, however, in this locality.

We look for a bumper crop of honey this year. The prospects are the brightest for it that I have ever seen. There is more white clover than there has been for a decade.

I have a few two-year-old queens that I should like to replace with young ones. What would be the best time to do this—at the beginning of the harvest or near the end of it?

Mr. DeMuth, in his article on comb honey, recommends the dequeening of colonies that are preparing to swarm, and letting them rear a queen or giving them a laying queen in ten days or two weeks. Will the bees work with as much vigor during this period of queenlessness as they would otherwise?

Weston, W. Va., March 3. ADDISON GOULD.

[Mr. DeMuth is about right in his suggestion concerning requeening. The best time to raise queens is during the swarming season, when large swarm-

ing-cells can be secured from colonies that are doing good work in the supers; for we would not use even swarming-cells unless from a colony of good workers. Removing a queen, however, in the height of the honey-flow, has a tendency to check slightly the activity of a colony; but if the colony can have a vigorous virgin coming on, it will work almost as well as if it had a laying queen. But there will be danger that it will swarm out when the virgin takes her wedding-flight. As a general thing, however, where one has to buy queens he will find the best time to requeen is along in July and August, when queens can be secured at a low price, and when the interchange of queens will cause no interruption to the colonies. Then we always like to have young queens in the hive in the fall. Such queens will lay in the fall when old ones will stop laying entirely. A lot of young bees in September and October is an important factor in good wintering.—Ed.]

A Super-rest

I am sending a drawing of a simple article which I find very convenient. I call it a super-rest. The upper drawing shows a sawhorse arrangement which is easily made by any one. The lower drawing shows a box which is about as simple to make, and will hold smoker, tools, etc. The upper one shows a super

in place. The two ends of the holder should be about 16 in. apart. I find this a great help when examining hives, as I can place this near the hive, usually in front, and set the super or supers on it. It saves crushing bees, and your super will not fall over as they will do when set on end.

Mystic, Ct.

ELMER E. WAITE.

Honey Crop Practically a Failure in Australia

The honey season in Australia can be written down as a failure so far. While there have been isolated instances of good yields, the record generally is none at all, and bees dying or doing very little. There is a great shortage of pollen; and unless this alters very materially during the next six weeks the mortality of bees during the coming winter will be very great. The whole failure has been due to drouth; and now the rain has come, and the weather prophets say we shall get wet weather for another six weeks, or until the end of March. If this proves true, the outlook is not bright, because the season will be at an end by then in all places except the northeastern portion, where a flow from ti-tree can be expected.

Some beekeepers have lost all their bees, and some a portion through what is generally known as the disappearing disease. It is a sort of dwindling disease where the hive is left often with three or four frames of brood and plenty of honey, but no bees. I have never examined any of these hives to see if they had a supply of pollen. If not, that would account for the whole trouble. I will follow this matter up if I get the opportunity, and see if it is pollen shortage.

MAJOR SHALLARD.

South Woodburn, N. S. Wales, Feb. 10.

How to Inspect Hives for Foul Brood when Robbers are Bad

Please state how to inspect an apiary of several hundred colonies of bees all in a rush by inspector, preparatory to moving to another State before the honey-flow. This you said not long ago is easily done without starting robbing. I have never found any way yet. A tent helps but little.

New Plymouth, Idaho, April 4. J. O. BAIRD.

[If you are at all troubled with robbers, or if you desire to do your inspection work at a time of year when they are hovering about the hive, you will find it very slow work, and somewhat dangerous too, because a single robber can carry the infection to its own hive. Under such conditions we do not know of any thing better that you can do than to wait until a day when it rains just lightly enough to prevent robbers from flying, and at the same time allow you to open the hives and inspect every inch of the brood in the combs. A light rain does not interfere with the work, except that the bees are a little crosser. You will have to use a little more smoke; but when there is a light rain on, you can work much better than you would naturally suppose. If you can't wait for it to rain we would suggest that you work after dark. Get a small acetylene bicycle-lamp. Start it to going, and then have an attendant hold this lamp so it will shoot its rays right on your frames of brood that you are examining. You will find that you can work at night much better than you would naturally suppose. No robbers will bother you at this time, and you can examine every inch of brood. Of course, we should very much prefer daylight, because there is nothing equal to that kind of light for inspecting suspected brood. Looking over a whole apiary to inspect foul brood is a very slow operation, for the reason that every bit of comb in the hive must be thoroughly examined if there is any brood in it to see whether the brood has any diseased cells. Even suspicious cells must be examined carefully to see whether any diseased matter is below the capping. This kind of inspection work takes a great deal of time.]

We remember once spending nearly an hour looking over a hive where we thought there must be foul brood because we could smell it. We could find nothing of the disease, and finally we saw one suspicious cell that was capped over. With a pin we raised the capping, and, sure enough, under it we found a typical case of dead larva from foul brood.—Ed.]

Mold in Double-walled Hives and None in Single-walled

I have been raising bees for several years, and, I am glad to say, at a profit. Last year I began using some double-walled hives, and upon opening one lately I was surprised to find the lower half of six of the ten frames moldy, and forsaken by bees. The upper half was filled with honey capped over. The bees were crowded to one side of the hive on four frames which were partly filled with honey and new brood, which showed the queen was all right. The hive had plenty of bees in it for this time of the year; in fact, it was the strongest colony I had examined this spring. On the bottom-board there were about a handful of dead bees lying in a certain

moisture that was too thick to be called a puddle. Now, was this moisture caused by sweat? and did it cause the comb to mold? What I want to find out is whether the moldy combs are fit to be left in the hives, or should they be destroyed and hives furnished with new frames? I found upon further investigation that all the double-walled hives I had bees in had one or two moldy frames, while several of the single-walled ten-frame hives I have looked into are free of any mold.

Baltimore, Md., April 3. MARK R. DELAHAY.

[This mold will do no harm—in fact, we are apt to find it on the combs of strong colonies just after a spell of long winter confinement. The probabilities are that the colonies in your double-walled hives were stronger than those in the single-walled. If that were the case it would be easy to account for the presence of mold in the former and not on the latter. In our climate a colony in a single-walled hive will dwindle down and become comparatively weak, while in a double-walled the colony will hold its strength and sometimes be stronger in the spring than in the fall. However, it is a fact that most colonies wintered outdoors are not quite so strong in the spring as they were the previous fall. Now, then, if your colonies in the single-walled hives were weaker than in the double-walled hives, it would be very easy to account for the presence of mold in the former rather than in the latter.]

Yes, the moisture is caused by the breath of the bees. Where there is a large powerful colony in a hive it will send out considerable dampness. This strikes the cold air at the entrance, and condenses and runs down the bottom-board. In a single-walled hive a colony will not be as strong, as a rule, and not strong enough to send out much moisture; and the consequence is, there will be none found in the hive.—Ed.]

Honey for Making Labels Stick on Tin

On page 232 you recommend dextrine for pasting labels on tin cans. By your recommendation I purchased some, but found it worthless to stick on tin. I use a flour paste mixed with equal parts of honey and water, which sticks a label on tin so it is impossible to remove it without soaking. Use a light honey, as dark honey will stain through the labels after a time.

Grosvenordale, Ct., April 5. ERNEST RYANT.

[There is a great difference in dextrine. Some will give good results and some will not. Perhaps, however, a common paste made as you describe, with honey in it, will be the equal of any thing. A good many have spoken of the value of honey as an ingredient in any kind of paste or mucilage for sticking labels on tin.—Ed.]

Antics of Pollen-laden Bees

In the spring of the year when the bees are gathering their first pollen, the pollen-laden bees will come to the entrance of a hive containing a colony with a queen, and enter the hive hurriedly, as if they had been sent for. Some of the pollen-laden bees will go to the entrance of another hive, and will almost enter. Then they will come back out again, and then take wing, doing this repeatedly—sometimes entering the hive, but always coming back out again after a time, as if they were searching for something. That colony is queenless, without a doubt.

BEES SWARM IF THEY THINK THEY ARE CROWDED.

Bees will positively never swarm if they think they are not crowded for room. The facts in the case have nothing to do with it. They might have an abundance of empty combs in the supers, and get it into their heads that they were crowded for room in the brood-chamber, and swarm.

Jonesboro, Ind., March 12.

C. A. NEAL.

Capturing Swarms from Limbs of Trees

Last Thursday, June 22, I was spraying my apple-trees. Early in the afternoon I became aware that a swarm of bees was near. I heard them some time before I saw them. As soon as they came in sight I threw my old straw hat among them three or four times, and then began to throw dirt. After following the swarm as far as the river, the bees seemed to stop for a moment in the air, as if uncertain, then swung to the right and clustered on the limb of a sycamore standing on an island in the river.

While they were settling I went after a twenty-foot ladder and a saw and smoker. The ladder was long enough to reach the first limb of the tree, but I found that the limb above it was just beyond my reach. By walking out on the first limb, however, I found that I could swing over to a small tree, and, by climbing that, I could reach the second limb of the sycamore. I then went up without any trouble. I discovered that the tree was hollow, and that the main crotch was open. The bees had settled there, and I could touch them by reaching down my hand the length of my arm.

I first tried to smoke them out, but they did not respond to this method of treatment; so I called to one of the neighbors, whose house was near, asking her to telephone to my wife, directing her to bring me a brace and bit. By making use of these new means of warfare I bored a $\frac{3}{4}$ -inch hole below them, and they began to move. I then placed a small box in the crotch of the tree; but the bees sought refuge in flight, and clustered on a good-sized elm, away out on a large limb, ten feet beyond reach.

I tied some twine around the limb and sawed it off. The bees then clustered in two places—one section in the top of a small group of maples, the other on still another large limb of the elm. I sawed the large limb off; and when it struck the ground the bees joined their companions in the top of the maple-tree. This was within reach of my ladder, so I found it an easy matter to cut off a few small limbs and hive the bees.

The next day one of our neighbors telephoned that there was a swarm of bees in their dooryard, which I could have. In the evening another neighbor reported that a swarm of bees had alighted on their cornfield fence, and that if I wanted them I could get them and pay whatever I thought they were worth. I found them on a rail. They seemed to be at work, as they were flying to and fro. After I have hived them I found a very little comb on the rail.

Union City, Mich.

JOHN L. SWAN.

[Much of the nuisance of climbing trees and chasing swarms a mile or so crosslots can be avoided by clipping the queen's wings. However, it sometimes happens that a swarm will go out with a virgin from a cell that has escaped notice, and then there is nothing to do but to go after them, whether they may be up a tree or across the fields. If any one can invent a process for getting a swarm out of an inaccessible place on a high limb, he ought to be awarded a gold medal. It is sometimes nearly worth one's life to climb a tree, to say nothing of getting the swarm and bringing it down after securing it; and some swarms, after they are captured, are very ugly. When the limb is in the right position, one can slip a bag up under and around the swarm, tie the bag around the limb, and then let the limb down. But more often the swarm is located out on the end of a branch where it is impossible for any human being to go. To saw the limb off has a strong tendency to dislodge the bees; and if the limb is a large one it can not be handled, even after it is cut off. All of this emphasizes the importance of clipping, or using drone-traps; but clipping is much to be preferred. —Ed.]

Bees Wintered Outside Have Opportunity for Early Flights when They Can Get Pollen

In GLEANINGS for April 1 some one asks why it is that bees commence brood-rearing so much earlier when wintered outdoors than when wintered in the cellar; and also asks if it is not because of difference in temperature. Allow me to suggest that it is not due so much to difference in temperature as because of other conditions. Bees wintered outside, if they have opportunity for flight, are more vigorous than when wintered in the cellar, and will be likely to commence brood-rearing sooner. And, again, with a very late winter flight or a very early spring flight, they may secure more or less pollen, which is an inciting cause of brood-rearing.

If bees are taken from the cellar in February, and given a good cleansing flight, and then returned to the cellar again, I think that brood-rearing would be started as soon as though they were wintered outdoors.

Evanston, Ill., April 3. WM. M. WHITNEY.

[It does not always happen that outdoor bees will have more brood in early spring than those that are wintered indoors. Last winter our inside bees reared brood earlier, and had more of it when set out, than the bees outdoors. Why it was so will be discussed at a later time.—Ed.]

Bees Working on Shorts as a Substitute for Pollen

I have been much interested in watching the bees gathering shorts, for, or in lieu of pollen, my bees have been foraging in the stables all over town the last few days after the ground feed. Several persons have told me that there were so many in the stable that they thought there was a swarm. To-day I placed some shorts in a pan in my beeyard, and some of the bees soon found it. They seemed to be afraid to alight on the feed—at least so I thought, but I found they would fly down into it and gather all they could in their mandibles and on their feet, using their feet to push the shorts into their mandibles and on their tongues, which latter were extended all the time. They would then rise up an inch or two, and with their feet brush off their mandibles and tongues, and pack the material on the pollen-baskets on their hind legs, repeating the operation till they had a load. They were not still an instant, wings and legs working rapidly all the time.

I have often wondered how they could pack the dry meal on their legs; but they seem to moisten it with their tongues, and then pack it on, using all their legs in doing so. I have never before had occasion to furnish my bees with artificial pollen; but we are having summer weather just now, and there are few flowers in bloom, so the bees are ravenous for some substitute for pollen.

Nederland, Texas, Jan. 23.

J. H. WEEKS.

Origin of Custom of Beating Tin Pans when a Swarm Issues

With reference to a recent statement in GLEANINGS about the practice of making a noise with pans, etc., when swarms are on the wing, and the origin of the custom, allow me to say that this is a relic of an old English law which says that any beekeeper, by giving notice to the public in this manner, has a legal right to follow a swarm wherever it may go so long as he can keep the swarm in sight. If, however, the beekeeper loses sight of his bees after giving this warning, they become the property of the person on whose land they alight.

Our Homes

A. I. ROOT

Be ye clothed with humility.—I PETER 5:5.

Blessed are the meek, for they shall inherit the earth.—MATT. 5:5.

Charity is not easily provoked . . . beareth all things, believeth all things, hopeth all things, endureth all things.—I COR. 13:7.

When I first began reading the Bible with an enlightened conscience years ago my good wife was often shocked and almost alarmed because I not only smiled but sometimes laughed outright. The good woman had been brought up to look at the Bible and every thing pertaining to it as something so sacred and solemn that one should not only look sober, but grave and serious when consulting its pages. Some of you may remember that years ago one scarcely smiled in prayer-meeting; and to laugh outright there, would have been considered a grave breach of etiquette. Things have changed. Well, I think it was when I was reading the "beatitudes" that I laughed, especially when I came to the 44th verse of the fifth chapter of Matthew, where we read, "Love ye your enemies; bless them that curse you, and do good to them that hate you," etc. The thing seemed so unnatural, and I do not know but it seemed to me then so *utterly unreasonable*, that I laughed outright at the new presentation of this wonderful truth. I soon put it in practice, or tried to do so, and the older readers will remember the victories that I achieved by following out the teachings of that chapter. One would think after these years of experience along this line that I, A. I. Root, the author of these Home papers, would not be likely to be ensnared, especially in the 73rd year of his life, after having taught the doctrine of returning good for evil for close on to forty years.

I am going to tell a story of my conflict with the enemy in two different ways; and I shall try hard to make both of them truthful. It occurs to me right here that I want to ask grace and wisdom from on high while I tell my little story. May I be clothed just now with that garb of humility mentioned in our first text, even if that garb was allowed to drop off and be trampled in the dust for a little time.

I think I have mentioned before in these pages that some of the boys in Bradentown had a fashion of hanging on behind my automobile. At first I did not mind it much; but when too many of them hung on, it hindered progress and I ordered them off. Mrs. Root asked me if I was not a little harsher in my demand than the occasion required. I replied that it was an outrage,

and that nothing but severe talk would make the boys behave. Later on, when I had a flat tire they loaded down the machine so the engine could scarcely pull it. At this I ordered the boys off the vehicle, and told them to get clear away, and in terms not very gentle. A good many times I put on speed and ran away from the boys; but after dark they would slip up unnoticed; and before I thought about the cause, I imagined there was something wrong about the machinery. Finally one night on my way to prayer-meeting, when I was obliged to slow up on account of some piles of material for repairing the road, they stopped the machine entirely. They not only got hold of the springs behind, but they grabbed hold of the wheels, stopping the machine so I had to crank it to get under way again; and as soon as my attention was taken up by running they stopped me again. I threatened to have them arrested, but they replied by shouts of merriment.

I got to meeting late. My conscience began troubling me; but I defended myself by saying that the good of the community demanded that the boys be arrested for laying hands on my property and interfering with my free passage of the street. I consulted neighbor Rood, who is a fairly expert attorney (or has been), as well as market-gardener, and he is also superintendent of the Presbyterian Sunday-school. Friend Rood declared it was an outrage. He said the only thing to do was to get the boys' names. I told him that none of them would give me the names of the ring-leaders. He said if it were himself he would get out and "chase them down." Said I, "Mr. Rood, have I the legal right to lay hands on any of these boys, even under such circumstances?"

"Mr. Root, I would chase them up, and lay hands on them without any regard to the law."

I think he added something more; but my conscience began to utter a vigorous protest. I think that the little alarm-bell I have told you about in times past began to ring out pretty vigorously, to the effect that A. I. Root, who writes these Home papers, would be sadly out of place chasing schoolboys, even if they did run out of the schoolyard to annoy him in passing along the street with his automobile.

I went home and prayed about it, and asked the dear Savior in plain words if I should chase the boys. Almost before the

words were uttered the answer came, strong and distinct, "No."

"Dear Lord, shall I complain to the sheriff about the boys?"

The answer came clear and plain as before, "No."

Once more, "Shall I scold them or threaten them with arrest?"

Again came the decided "No."

At this point I asked Bro. Rood another question:

"Mr. Rood, do you know or have you heard of the boys interrupting or annoying anybody else who drives an automobile on our streets? I suppose there are a hundred of them or more in and around Bradentown. His reply was, "Mr. Root, I have never heard of their interfering or interrupting anybody else."

I told him that this pointed out the fact that I was at least *partly* at fault if not entirely so; and I went home to consider the matter. Shortly after, I ran on to the following in the *Sunday School Times*. Read it, and see if you can catch on to where it hits your case.

TRANSLATING COMMONPLACE TRUTH.

When any truth seems commonplace to us it has lost its power for us. How can that power be restored or discovered? Coleridge gives the secret when he says: "To restore a commonplace truth to its first uncommon luster, you need only *translate it into action*." "Blessed are the meek" is one of the familiar promises that often has little appeal; but how it bristles with surprises and with power when it is turned into action! Every promise of the word may be found to contain the life-giving Spirit of God when it is translated into the uncommon language of life.

Let me now tell my little story again, relating some facts I have neglected in the above.

Years ago, when I got my first automobile, or "Oldsmobile," rather, it had a back seat; but the passengers on the back seat were obliged to ride backward. To get on this back seat there was a step not very far up from the ground. To get on to this step there were iron rods to grasp hold of on each side. Now, this back step was exceedingly handy for carrying parcels, merchandise, etc., and we liked to use it for that purpose. This back step was removable; but when we tried leaving it on all the time we soon discovered that it was a great temptation to mischievous boys. Even when going at considerable speed a boy could grasp hold of the iron rod and swing on to the seat. This sort of sport was attractive, because one could thus get aboard very much as a conductor dextrously swings on to the steps of a fast-moving train. The boys soon became very expert; and while here in Medina we left the step at home because the boys would load us down. I had

the machine shipped down to Florida. But I soon found that the boys in Florida were not particularly different from the boys in Medina. At first I wanted to be pleasant and good-natured to the boys, and permitted them to ride; but when it began to be too much of a burden for the old machine, I asked them to get off. Some of the boys heeded my request. Others did not seem disposed to move; and if they did get off, as soon as my back was turned they got on again.

In this way, and with an old machine, I educated the schoolboys to be ungentlemanly. When I got a new Sears automobile they recognized *me*, even if they did not the machine, and began climbing on behind. I finally scolded, and then threatened. I forgot my religion. My cloak of humility that I usually wore was neglected, and fell from my shoulders. Satan saw a chance, and he followed it up. There is an old adage to the effect that it takes *two* to make a quarrel. At first I defended myself by saying I was entirely right—the fault was *all* with the boys. Moses has been called, I believe, the meekest of men. Just once in his life he became angered, and forgot himself and his dignity before the people. He said to the grumbling children of Israel, "Ye rebels, must *we* now fetch you water out of this rock?" I, like poor brother(?) Moses, forgot the text I have been quoting to you for lo these forty years, and was quarreling with the boys. I think there is an old saying that goes something like this: "It not only takes two to make a bargain, but it takes two to make a quarrel." The boys were unquestionably rude and in the wrong; but I too had been rude and in the wrong or else there would not have been any quarrel. Let me digress a little.

Years ago, as our readers will remember, I was an enthusiastic truck-gardener—at least in an experimental way. One year my hobby was nice Hubbard squashes; and knowing from former experience of the fight I would have with the bugs I provided some square boxes, one for each hill. These were made by nailing four shingles together so as to make a square box. The thin end of one was tacked into the thick end of another; and these square boxes were covered with cheese-cloth, and kept in readiness one particular spring; but, lo and behold! the bugs did not trouble us that season—at least not one had been seen until a warm spell about the last of May. But one Saturday night, just about sundown, after my help had all gone home, a great swarm of bugs camped down on my precious handsome squash-plants. I rushed to the house,

and on my way I mentioned to Mrs. Root what had happened. She said something like this:

"Oh dear me! Is it not too bad that they should come Saturday night, and after your help has all gone?" But when I looked up and replied, with a smiling face, that "to tell the truth, *I was glad to see them*," she looked at me with something of the same astonishment she did when she heard me laughing, when I was reading the Bible.

"Why, dear husband, you do not mean that you are *glad* to see those swarms of bugs come here late Saturday night, do you?"

"Yes, my dear wife, I mean exactly what I say. *I am glad to see them.*"

I was anxious for an opportunity to test my proposed remedy, and it proved to be all I had hoped.

Perhaps I might tell you right here that, about the time I was having my tussle with the boys, our good pastor of the Presbyterian church asked me to lead the prayer-meeting on the following Thursday night. The subject he gave me was "Christian humility." Perhaps I startled some of the good friends on that prayer-meeting night by telling them the above story and adding that I was at that very time praying for grace to say to the next crowd of boys who came near, just as I said to the bugs, "Boys, *I am glad to see you.*" And I asked the friends to pray for me that I might have grace to say from the bottom of my heart, to say it truthfully, "Boys, I am glad to see you." I began to think, just as the time was nearing to go back to my Medina home, that no boys were going to come near. I realized that I had undertaken a big job. Just take a look at it. Suppose a gang of hooting and yelling schoolboys looking for fun somewhere should say, "Let's hold up that old gray-haired gent who wears a fur cap, and hear him scold. He does not know our names, and he can not harm us much any way."

Years ago, after kneeling with my poor friend Fred, whom I have told you about, on the cold stone floor of the Medina jail, and after poor Fred had prayed for himself, he took a look at that text I have been talking about—"Love ye your enemies; do good to them that hate you," etc. He said something like this: "Mr. Root, that may be all right. Perhaps it will work out as you say; but I tell you it goes awfully 'agin the grain.'" And Fred was right. It does go "awfully agin the grain" even to *try* to love our enemies; and I felt it when I approached the conflict. I told Mrs. Root I hoped the boys *would* test my Christianity at least once more; and I

told the honest truth. I did not want the boys to do wrong and be unceivl to the traveling public; but I did feel anxious to have an opportunity to show that I was a changed man—changed at least in *some* respects, as poor Jacob was changed after wrestling with the angel. The test came. The boys, three or four of them, with mischief in their looks, ran down and held on to the projecting springs at the back of my automobile, while two more of them grasped the wheels; but when I slowed up and looked at them pleasantly they were astonished. They had planned for harsh and severe words; but they had not planned for the soft answer that "turneth away wrath." When they saw I was pleasant, and had not a word of reproof for them, they looked at each other in perplexity. What could it all mean? They retreated a little, thinking that may be I had some firearms or something else. When they stood off a little distance at the side of the road I did not tell them in so many words that I was glad to see them. I feared they might think that it was only sarcasm; and the Holy Spirit instructed me that sarcasm has no place in the heart of one who is "clothed with humility," as in our text. I simply scraped up grace enough to say, "Boys, one of my tires is in bad shape, as you will notice. I expect to go north soon, and am trying to get along with it as it is until I go away. I do not believe you would willingly hinder me under the circumstances, would you?"

At this unexpected turn of affairs a little chap looked toward an older one who seemed to act as leader. He simply said, "Don't meddle with it, boys, any more." Then they turned and went away. Years ago I said, in considering this subject, that returning good for evil is a great *unexplored region*, and that the world had not yet even dreamed of what could be accomplished by heaping coals of fire on the heads of our enemies. I have taken a good deal of space to give full particulars of the above transaction, because it carries a tremendous moral. You see how easily I could have fanned the flame of hate. Inadvertently I had started the boys in this way of having sport at the expense of somebody else. I confess, my friends, it is a pretty hard pill to swallow, to treat such conduct as *fun*, and avoid stirring up strife. The boys had the advantage, because they could come up behind when I could not see them. They could have their fun under the cover of darkness. Having them arrested and put in jail might have aroused their bad feelings so they would have retaliated by cutting my tires or otherwise damaging my automobile. This

has happened more than once. Judge Lindsey, who has done so much for the boys in Denver, Col., by looking at things from *their* standpoint, has taught us some wonderful lessons; and these lessons are taught all over our land by great and good men who are stepping down a little, and standing beside the mischievous and fun-loving juveniles.

Just now our State of Ohio is discussing a proposition from the brewers to punish the boys found in saloons, if they are under age, instead of punishing the saloonkeeper. The latter entraps the boys, coaxes them into his place, and then these poor misguided boys would be fined and imprisoned for breaking the law while the saloon-keeper goes scot free. May God be praised that the evidence, as I now write, points to a failure of this scheme of the brewers. Now, my good friends, to come right down to practical work, how many times have *you* fanned into flame a quarrel between your-

self and your neighbors instead of quenching the flame and seeing it die out along the line I have indicated?

In making this little personal matter public, perhaps I shall expose myself to more trials. If so, may God give me grace to keep pleasant, and put up with whatever little persecution may follow. As a goodly number of our journals go to Bradentown and vicinity it would not be strange if some of those same boys would get hold of it and decide to give me a harder trial than I have had yet; and may the dear Savior give me grace and wisdom to remember that these very boys are the ones for whom he suffered on the cross that they might live. Just one thing more: I was going to say that I am one of the meekest and humblest of his followers, but I do not merit that distinction yet; perhaps I may, however, before I die. May the dear Savior give me grace to say as he said, "Father, forgive them, for they know not what they do."

Poultry Department

DUCKS AND CHICKENS IN FLORIDA—SOMETHING ON THE OTHER SIDE.

Mrs. Root is continually telling me that there is danger of my leading people into error by giving only the rosy side of most things; and she says I have not mentioned some of the difficulties with ducks and chickens in Florida, especially for those who, like ourselves, spend only the winter here. Just now, for instance, in the middle of April, when I am planning to go back to Ohio, I find it difficult to find somebody who "wants the job" of caring for my poultry until I get back here next November. One year I let a neighbor have the grown-up fowls for the eggs, and he thought he did fairly well. I paid him only for the trouble of taking the fowls home and bringing them back. The next summer, however, when there were a lot of "youngsters" also, it was a different problem. The year after, another friend kept my grown-up fowls during the summer. He said he could not tell whether the eggs paid for the feed or not; but as he was a particular friend he made no bill for the trouble or feed. Just now, however, nobody seems to want them. As I have sold off my old hens, there are only about 125 chickens, young and old. A dozen of them are about four months old. In Florida they rarely begin laying before six months of age. Well, under the circumstances I offered to furnish *all the feed* and give the neighbor the cockerels for taking care of them. There will probably be fifty

or sixty roosters that will bring, say, half a dollar each when they are large enough; so he will get from \$25 to \$30 for just seeing that they have feed in their galvanized tubs, and that the windmill keeps the water "dripping" all the time. He also has the eggs laid by 25 ducks for the work of shutting them up nights and letting them out mornings.

From the above you will probably notice that I had better sell my chickens in the spring when I go back north, and buy some more when I get back in the fall. But here is the point: I have a special strain of a cross between Buttercups and White Leghorns that I like better than any thing else. This cross not only seems to give more eggs than either before crossing, but so far there has been a smaller percentage of males than pullets. And right in here comes another difficulty with the Indian Runner ducks, especially in Manatee Co., Fla. Up in the North, growing green ducks for the market is a great industry, and people pay big prices for these green ducks ten weeks old. Not so down in Florida, for here there is a prejudice against ducks, young or old. The women folks all say it is a lot of work to get them ready for the table; and the people at the meatmarket say the same thing. In fact, nobody will give as much for a fat young duck down here as for a chicken. We do not care particularly about selling the *ducks*, *young* or *old*; but the *drakes* in every flock must be disposed of in some

way, or they will "eat their heads off." I sold a few year-old drakes, that I did not need, for only 8 cts. per lb. because nobody would give more. They weighed about 5 lbs. each.

Now I have told you the worst side of the poultry business—first, getting the chickens not old enough to lay kept through the summer, and keeping the old ones through the moulting season; second, in the duck business, getting rid of the surplus drakes.

The duck-books tell us that people can be *educated* so as to appreciate and pay for green ducks; and they also tell us about experts who will pick a duck and get it ready for the table in *three or four minutes*, while Mrs. Root declares it takes a good part of the whole forenoon; and she has consulted other women who feel a good deal as she does about it. And she thinks a nice fat chicken is ahead of a duck after it is ready.

CHUFAS FOR CHICKENS.

In answer to Mr. A. T. Cook's letter, April 1, I wish to say a word about the chufas. My father's family used to object to planting chufas close to the house, for we always thought that meant "no eggs." But one spring my father planted a little over an acre of chufas near the house in some rich cow-pens, and just as the nuts began to mature the chicks took to them, and, to our surprise, we got *more* eggs than we had ever got before, in the fall and winter.

Cody, Fla., April 14. HENRY F. STAFFORD.

Friend S., I am very glad to get the above, for the reason that one of our neighbors in Florida thought his hens stopped laying just because they had access to a plot of ground where he had been growing chufas; and if I am correct there has been a sort of notion, as you say, that chufas are not good for eggs, and we have now two instances showing quite conclusively to the contrary. I am glad; for if true it cuts out the expense of harvesting the crop. If I am correct, the chufas may remain in the ground, especially in localities where there is no freezing, for a considerable length of time without injury. We are giving them a further trial.

HAWKS AND CHICKENS; HOW A TEXAS WOMAN DOES.

Mr. A. I. Root:—Many a time I have been tempted to write to you after reading your Home talks in GLEANINGS. These Home talks always interested me, and after reading about your trouble with hawks I want to tell you my way of scaring them away.

Last fall and winter I hatched with an incubator over 200 chickens. Some of them disappeared during day time. For some time I could not believe that a hawk caught them, as I never saw any close around the house. After I had lost between 25 or 30 my son noticed a hawk catch a chick and fly off with it. The day after, I saw the same performance myself. The hawk must have been pretty high up in the air, for I was in the yard, where no tree or shrubbery was in my way. All of a sudden he came straight down, about 35 or 40 yards from where I stood, grabbed the chicken, and off he went with it, almost

like a streak of lightning. After that we watched for him and shot at him several times, but failed to get him.

Then I fixed up several scarecrows as follows: I took a pole about six feet long; got some of the boys' old clothes, slipped a stick through the sleeves for arms, nailed this on the pole, then slipped the trousers over the pole (just one leg, and let the other hang loose). Then I made a head of rags, and fastened an old hat or cap on it; then fastened a bright tin lid from lard-buckets, with a cord on the end of each arm. The wind will keep these lids in constant motion, which seems to frighten the hawks. I set up these scarecrows against a fence or bush, and sometimes drive a slab in the ground and nail it to that. I have six of these guards around my premises in different directions as far as the little chickens go.

These guards are no beauties, and people laugh at them in passing; but I don't care, for they certainly frighten the hawks away. I have not lost a chicken since I put them up. There is no expense about it, and no more worry.

A man told me a few days ago that, if you put up a pole about 12 or 15 feet high, nail a stick about 5 feet long across the top, and fasten tin lids on the stick, it would answer the same purpose. May be so. I have not tried it.

I keep only the Silverlaced Wyandotte chickens. They are fine layers all the year. I wish I could see your hen-houses and other fixtures. I am the only one of the family who likes to work with chickens, and consequently I am not fixed up for poultry-raising as I should like to be.

MRS. GRANT ANDERSON.

San Benito, Texas, April 23.

The above reminds me that my neighbor Abbott has a similar device, but he uses cheap looking-glasses or pieces of broken mirrors instead of tin. I must confess that I rather dislike to see scarecrows very near the home; but I think I would put up with a good deal as Mrs. A. does, rather than lose chickens at the rate she did; and I believe it is generally true that when a hawk, vicious cat, or other animal gets into the fashion of having a chicken dinner every day it will usually follow it up unless something is done.

HAWKS AND CHICKENS; COTTON STRING INSTEAD OF NETTING.

In your issue of April 1 Mr. A. I. Root tells of his experience with little chickens and those hated marauders, the hawks, and how he covered his runs with netting wire to protect the young poultry.

We have found a very simple mode of protection which works like a charm in keeping away the hawks that live around Wachusett Mountain here in central Massachusetts, and pass it on to you with the hope that others will try it and find it successful. The rule is this:

We string crowline—white bundle twine will do if one has enough—across the open spaces where the hawks have been in the habit of swooping down, fastening the line on buildings, trees, posts, etc., high enough above the ground to be out of the way of pedestrians, cattle, and teams. We have never known a hawk to venture beneath or between these lines. Apparently they are plainly seen by him as he soars about on the wing, and he suspects a trap has been set for him. I hope other poultry-raisers in other localities will try this way of keeping these marauders away, and find a happy success. It is a far less unsightly procedure than hanging heterogeneous collections of cast-away articles before the eyes of passers-by—a way of attempting protection that often fails to save the precious chicks.

MASSACHUSETTS READER.

Health Notes

ROBBING SICK PEOPLE.

In this age of life we have, thank God, a great variety of reformed people. We have repentant and reformed grafters, reformed saloon-keepers, reformed drunkards, and reformed gamblers; but a good friend of GLEANINGS just now sends a clipping from the *Weekly Kansas City Star*, giving at length the confessions of a "quack doctor." This doctor gives the method in detail by which men of his class bleed their victims. The patient is first required to take a bath before the examination; and while one quack examines (or pretends to examine) the nude patient, another quack examines his pocketbook, and looks over all the papers he can find in his pockets to learn, as far as possible, how much the victim will stand bleeding—that is, financial bleeding. The plan is to get (to adopt a railway phrase) "all the traffic will bear," no matter whether there is real or imaginary trouble. To tell the real truth, the quack doctor would not know and really does not care. The patient is always assured that it was a lucky thing that he came to a competent physician—that unless something was done, and that at once, he had only a few months or weeks to live. Of course, this quack institution has a variety of instruments, electrical, chemical, etc., so as to make a big show; and, to be brief about it, instead of studying up ways and means to *help* the patient, they go through a great variety of performances to squeeze out the last copper the patient has.

Now, I have been through this very thing during the past fifty years; and, to be frank, my opinion now is, on looking back, that about all I needed (most of the time) was to get out in the air and sunshine and to get into a good perspiration by doing some useful work before I sat down to my desk, to attend to correspondence, etc. This "confession," and I feel sure it is a true one, almost makes the chills run down one's back to think that any human being should be so depraved as to resort to any such despicable means to get a poor man's money—money that he has worked hard for—without giving him any sort of equivalent. The highwayman knocks a man down and rifles his pockets; but he generally selects somebody who is measurably able to take care of himself; but these thieves hunt up people in the last stages of consumption, or some other incurable disease, assuring them that, in a few months or weeks, by *their* special treatment and wonderful(?)

discoveries they will make him as "sound as a colt." A part of the paraphernalia consists of putting the patient on a stool with glass legs, and giving him electricity; examining his blood under a microscope; and then telling him his case is hopeless, and that, if he had only come three months sooner, they might have helped him. But they finally make a further examination, and tell him that, if they get *right to work*, there *may* be a chance to save his life. If I am correct, however, our good Uncle Samuel is getting after these chaps, and I hope he will make it hot for them, and do it speedily.

I am rejoiced to see that the World's National W. C. T. U. has sent out a four-page leaflet in regard to medical frauds. I copy below the first two of the 24 mentioned and described:

What is Sanatogen?

According to the manufacturers of it, 95 per cent of it is casein, the curd of milk, and five per cent sodium glycerophosphates. The *Journal of the Am. Medical Association*, Feb. 19, 1910, says that one dollar's worth of Sanatogen is equal in food energy to six cents' worth of milk or one cent's worth of flour. There is nothing harmful in Sanatogen, but there is great waste in buying milk-curd at such a price.

What is the Oxypathor or Oxygenator?

This little device, for which \$35 is asked, is said to pump oxygen in vast quantities through the pores of the skin. All physiologies teach that the power of the skin to take in oxygen is extremely limited. Oxygen enters the lungs through the nose and throat. This is amply proved by the quick death which results when the intake of oxygen is shut off by pressure on the windpipe. The Oxygenator, the name of which was later changed to Oxypathor, was examined by Vermont State Board of Health, which declared that it was merely a piece of pipe, resembling gas-pipe, nickel-plated, with the hollow interior filled with a rough mixture of iron filings, clayey material, and coke-dust. This Board of Health forbade its sale as a fraud. The Commonwealth of Australia forbids its importation as a fraud. As claims are made for this costly and useless device to cure even so dangerous a disease as diphtheria, the public should be warned everywhere against it. The "cures" attributed to it must be of the "mind-cure" variety.

What do you think of charging a dollar for a little "cottage cheese" with a string of testimonials from great(?) doctors? In regard to Oxypathor or Oxygenator, our older readers are doubtless aware GLEANINGS has been fighting this fraud for fully twenty years. If Vermont can forbid the fraud, why can not our whole United States protect her sick and suffering people, who have no means of detecting humbug and trickery from real sense and science. God bless the W. C. T. U. "Long may they wave!"

High-pressure Gardening

THE REJUVENATION OF ORCHARDS.

Our Ohio Experiment Station has just sent out a most valuable bulletin, No. 240, on the above subject. I have not space to make as many extracts as I should like; but I am going to give you a single paragraph from the last page of the book, as follows:

Previous to 1909, Washington Co. was buying her apples for home use. In the year 1909 a number of demonstration experiments were started in the southern part of the county by the Ohio Experiment Station, as well as in a few orchards leased by private parties from a distance. The income of the county, from the sale of apples in 1909, from unsprayed orchards, was less than \$5000. In 1910 the income increased to \$65,000; in 1911 the income from the apple crop advanced to \$200,000. The work has but fairly begun. It is the marvelous spectacle of the reawakening of a practically lost industry in a section where that industry was, many years ago, one of considerable importance.

The above very fairly illustrates what is going on of late in the way of making old neglected orchards good for something. Just think of it! A county that has been *buying* apples, after a little care of its old orchards has actually *sold* \$5000 worth. In just one year from that time they made a tremendous jump up to \$65,000; and in just one year *more* they made another jump that almost takes one's breath away—\$200,000.

SWEET CLOVER, AND INOCULATING CLOVERS IN GENERAL BY NITROGEN BACTERIA, ETC.

At present writing, May 1, almost if not quite all the agricultural papers of our land are recognizing and giving place to articles on sweet clover. From the *Prairie Farmer* of May 1 I clip the following:

GLUE METHOD "FOOL PROOF."

H. L. Kendall Co., Ill., writes:

"I should like a little information in regard to inoculating clover seed by the glue method. I expect to sow a few acres this spring just to try it, any way. The wild plant grows very rank along the road on the south side of this field, also some on the east side. Might not the field receive inoculation from this? I should like to know how much dirt I should use per pound to get the desired result."

If the surface water runs over your field from where the sweet clover grows, you would probably in time have the sweet-clover bacteria thriving throughout your field; but when it is so inexpensive, and so little trouble to be sure about having artificial inoculation it is foolish to take any risk in getting a natural inoculation.

The glue method is not only cheap and easy, but it is nearly "fool proof"—that is, it is not necessary to be very particular about all the details to have it successful in its results. A pound of glue may be dissolved in a gallon of water or in two or three gallons of water, without any appreciable difference in the results; and a quart of dry dirt or a gallon of dry dirt may be sprinkled on the seed after they have been moistened with the glue water. As a rule, about a quart of dirt may stick to the seed, and the rest of the dirt may be screened out or not, just as you prefer, as the amount of dirt is not ma-

terial, if there is enough. In preparing the dirt, however, a little care should be used to secure it from a place where the bacteria are active, as shown by the nodules formed; and if the host plant, in this case sweet clover, has grown in the same place for several years the inoculation will be better. This dirt should not be dried in the sun, as direct sunlight is fatal to bacteria of nearly every kind. The dirt should be finely pulverized and sifted through a fine sieve, but this is not much trouble, as so small an amount is used.

The natural inoculation carried by water from high land is likely to be spotted and unevenly distributed, while the inoculation from the dirt-and-glue method is carried by the dirt to each and every seed, and the bacteria are ready for work as soon as they can sufficiently develop.

In the case of small seed, like clovers, a solution of one pound of glue in two gallons of water is satisfactory, and then the solution is so dilute not many lumps of seed are formed by sticking together. If there should be, it is easy to rub and screen them out.

FRANK I. MANN.

Please notice from the above that the expensive methods advocated of late by our government and all our agricultural papers, recommending transporting soil from where sweet clover has been growing to their fields, promises to be done away with. Instead of a ton of earth, you do not need more than a quart or such a matter. The above is certainly a short cut, and our thanks are due to the *Prairie Farmer* for having given it to the world.

"AND A LITTLE CHILD SHALL LEAD THEM."

Some time ago I said our boys and girls would soon be outstripping their fathers in growing potatoes as well as corn. See the following from *Rural New-Yorker*:

CHILDREN'S POTATO CROPS.

On page 344 is an article entitled "The World's Potato Record," and I thought if that was considered a record perhaps some of your readers might be interested in a record that some of our boys and girls made last year, so I enclose a report that was published in a local paper at the time. This contest was started by myself; but a committee, composed of a member of the Y. M. C. A., the Chamber of Commerce, the County Superintendent of Schools, the Grange, and the Agricultural College were asked to and did help with the contest. Two hundred and twenty-seven boys and girls entered; and in spite of bad weather, blight, and other discouragements, 85 came clear through and made their showing at the fair held for that purpose. The plot of ground was one square rod, and no potatoes were counted that were dug outside of the 16½-foot limit. The judging was on a basis of 60 points for quantity, 25 for quality, and 15 for essay. The best yield was 587 pounds; second, 535 pounds; and then there were several in the four-hundred-pound class. This year the contest is State-wide, and includes, besides potatoes, wheat, oats, corn, and peas, besides stock-judging and school-garden contests.

Washington.

C. E. FLINT.

The first prize was won by Arthur K. Collins. On his rod of ground Arthur raised 587 pounds, or at the rate of 1565 bushels per acre. His prize was a scholarship at the Agricultural College and a \$15 account in a bank. Charles Banner won second prize, \$50 worth of land and \$10 in cash. He raised 535 pounds, or at the rate of 1440 bushels per acre. One of the girls, Jeannette Gilmore, raised 342 pounds, or 920 bushels per acre.—ED. R. N. Y.

Temperance

THE NEXT ADVANCE—A CRITICISM ON THE PROHIBITION PARTY AND THE ANTI-SALOON LEAGUE.

Mr. Root.—I notice the reiteration in GLEANINGS of Chafin's unkind fling at the Anti-saloon League, and I for one raise a protest. Since 1888 I have steadily supported the national Prohibition nominee for no other purpose than to crystallize into a working force the prohibition sentiment. It matters not how well or ill the standard-bearer conducts himself under the fire of enemies, whether open foes or concealed enemies of the cause, the duty of the voter is to vote his sentiment, nor be affrighted by the blowing of a leaf.

GLEANINGS has previously asked the question, "Can't we get together?" and in this latest utterance reveals the reason why we can't; for it is the same reason from Maine to California, and from partisan and non-partisan alike. The blowing of a leaf causes affright.

We will get together. No vaporings on either side shall deter. The time for close-range action is at hand. GLEANINGS, not being an organ for either side, is just the paper to propose and be heard in this matter.

I believe the Prohibition party has blazed the way to the annihilation of the liquor-traffic by teaching men to vote for *what they want* in legislation. The Anti-saloon League is but a child of the parent. The public measures a party by the number of its votes. The Prohibition party is infinitely bigger than its vote. The Anti-saloon League is larger than the number of its contributors; but a discussion of these is not intended here. What is wanted is future plans. Let us amalgamate. It will hurt our pet hopes; but, no matter. The end sought is the only good. Here is a plan:

A national convention of all prohibition forces to be held in Indianapolis next fall. Let the political powers disband with flying colors, and a new organization take the places of the Prohibition party and the Anti-saloon League. Let our leaders have time to bring into being an organized unity that will be invincible, not seeking the spoils of office, but raising the penalties and making repulsive the liquor-traffic and its hangers-on; and let no one stand in the way.

We will get together, and end the tragedy, though it cost a thousand lives instead of trampled feelings. Bladen, Ohio, Jan. 6. CHAS. H. CARGO.

Amen to the above, Bro. C.; and if it is true that I have been disturbed by the "blowing of a leaf," as you express it, I will try to scrape up a little more faith, and perhaps a little more patience and humility.

By the way, I have just had a letter from Superintendent Baker in which he declares that, since the brewers have failed to keep their promise in such a shameful manner in regard to license in Ohio, there is no course now except for *all* the temperance people to join together and demand Statewide prohibition. As I understand it, this would mean the Prohibition party and the Anti-saloon League can work together (at least in Ohio) as a unit. May God hasten the time.

DON'T KEEP BEES, BUT KEEPS "BUSY."

On page 176, Feb. 15, I suggested that "L. R. H." must be a beekeeper. It seems he got hold of that number of GLEANINGS, and replies as follows:

To A. I. R.:—No, I do not keep bees. I keep busy. L. R. H.

Let me explain further: L. R. H. stands for L. R. Horton, of Spokane, Wash., the publisher of a bright little pamphlet entitled "101 Shots at the Liquor-traffic." The price of this attractive little book of about a dozen pages is a nickel, or by the quantity \$2.00 per 100, and they are being scattered by the thousand all over the world. The little book is *red* outside, and as a general rule it is *read* inside by everybody who knows how to read. A man in Illinois was so much taken up with it that he ordered \$8000 worth, and he is going to send them to Sunday-schools and to their superintendents throughout the United States and Canada.

HOW ARKANSAS IS "KILLING TWO BIG BIRDS WITH ONE STONE."

We clip the following from the *Cleveland Plain Dealer*:

ARKANSAS BARS SALOONS.

LITTLE ROCK, Feb. 10.—Final action was taken by the legislature to-day on a bill that practically prohibits the sale of liquor in Arkansas. It provides that a person intending to open a saloon must obtain signatures of a majority of white adults in the city or town in which he hopes to do business.

The measure is looked upon as practically a State-wide prohibition act, because names of white women as well as men must be obtained, and the negro population is not taken into consideration.

May God be praised for what Arkansas has done, and may other States speedily "sit up and take notice," letting *good women* have a voice in the matter, and also killing the drink evil with one bold "fling."

UNITING THE TEMPERANCE FORCES.

We clip the following from the *American Advance* of March 29, not so much because of the very kind words for the Home Department, but because the editor of a prohibition paper speaks thus kindly of a periodical that has been foremost in endorsing the Anti-saloon League from its start up to the present time.

PROHIBITION BEEKEEPERS.

It is said that there are more Prohibitionists among the beekeepers of America than among any other group of business men. At any rate, readers, editors, and publishers alike have reason to be proud of the brilliant representative of that trade, GLEANINGS IN BEE CULTURE, published at Medina, Ohio. Many strong blows against the liquor traffic have been struck by the veteran editor of this magazine, A. I. Root, who contributes to the March 15th issue, just out, a most compelling and suggestive discussion of civic righteousness under the head of "Our Homes." We congratulate GLEANINGS as well as its readers upon the continuously fine spirit of its editorial pages.

Editorial

HONEY-CROP CONDITIONS.

THE reports that have been coming from the white-clover districts of the country have been very flattering indeed. Heavy rains early in the spring, warm weather, sunshine, and more rain, have made it look as if there might be a big crop of clover honey. Even if a drouth should come from now on, we don't see how it could possibly prevent securing a fair yield of clover.

Further reports from California, as indicated in our California department, show that the season will probably be an almost entire failure in that State.

The alfalfa regions will probably yield their usual quota of honey. The southern part of the country will likewise have a fair yield.

OUR COVER PICTURE.

OUR cover picture for this issue shows a part of the apiary of R. N. Gidley, at Lakeside, Canterbury, N. Z., as mentioned in the article by E. G. Ward, on another page. In many ways American beekeepers may learn a great deal from their neighbors in New Zealand. The latter are facing many of the problems that we are facing in this country, and carrying on to a great extent the same kind of work. They are progressive and up to date. The ten-frame hive of Langstroth dimensions is pretty well standardized in New Zealand—a fact which we wish might also be said of this country.

Any American beekeeper might well be proud of this apiary, bearing as it does the stamp of up-to-date businesslike methods. Our next issue will contain further particulars.

There is a law on the statute-books of New Zealand making it possible to fine a beekeeper who persists in neglecting to attend to diseased bees. From the *Auckland Weekly News* of November 28, sent us by one of our subscribers, Mr. Robert Black, we learn that Mr. G. V. Westbrooke, the inspector, reported that one beekeeper, having failed to destroy or treat diseased bees after receiving notice to do so, was fined by the magistrate three pounds—that is, about \$15.00.

THE TIME TO SPRAY TO AVOID KILLING BEES.

SELDOM do we find a larger amount of valuable information on this subject, in a small amount of space, than is given in the *American Bee Journal* for May, page 151, by Mr. Frank Rauchfuss, of Denver. Among other things he presents is the statement made by Prof. Gillette, the entomologist of Colorado. He says:

When the codling moth begins to appear about the time of full bloom, they do not begin to lay eggs until the majority of the apples in the orchard are one-half an inch in diameter; when they are $\frac{3}{4}$ of an inch they are laid freely. As soon as the little apples lose their fuzzy coverings the moths lay their eggs very largely upon the cheek of the apple, but *never in the blossom*. Later they find their hiding-place in the blossom end of the apple. After the blossoms have fallen and the apples have attained a little size, *is the time to spray and not before*.

A good many up-to-date fruit-growers have the idea that spraying for the codling moth should begin just as the petals begin to fall. But this will catch some bees, as different varieties of apples mature at different times, and there will be early and late blossoms on even the same tree. If the fruit-grower will follow Prof. Gillette's recommendation he will avoid all possible danger of interfering with the interests of the beekeeper, and at the same time look to his own interests. Spraying at the wrong time wastes material and time.

BIG FIELD DAY AND CONVENTION AT AMHERST APICULTURAL SCHOOL IN MASSACHUSETTS.

ON page 326 of last issue we spoke of the big field day and convention that is to be held at the Massachusetts Apicultural School, Amherst, on June 11 and 12. We had not intended to be present and participate in this field-day work; but pressure from Dr. Burton N. Gates, in charge of the school, finally decided us to go; in fact, we felt that we could not afford to miss it, considering the efforts that Dr. Gates has put forth to make this meet a success. In a letter just received from him to-day, among other things he writes:

Mr. E. R. Root:—Besides yourself, Mr. Morley Pettit has promised to come. It is possible that Dr. Phillips may drop in, although he is not definitely provided for. He was here last year. There will be

eight or ten other speakers from throughout New England.

One session will be devoted to the discussion of the brood diseases of bees, their treatment and prevention, during which a prominent feature will be the discussion of the transportation of bees in combless packages, of which I have previously written your company. A number have already indicated their intention to send specimen shipments. This, of course, is in the nature of an advertisement, and should arouse the interest of beekeepers in the new and safe method of bee transportation. We shall also demonstrate the treatment of diseases during this session.

Another session will be devoted to general discussions. Your work will of course be concerning out-yards and the extraction of honey and most up-to-date methods using our equipment which is installed.

I shall announce also some of the features of the apiary equipment of this institution which includes a nectar-yielding garden which is being planted and maintained so that the beekeepers may see growing the more important nectariferous plants. There will also be for comparison several types of cement hive-stands.

Another feature will be the display of queens of the different races and types advertised in the country. The equipment of implements and beekeeping materials will be on exhibition and is known as the Massachusetts Agricultural College Apicultural Museum, which Phillips has designated as the most complete array yet gathered. This also includes some rare books on the subject.

Other topics which will be discussed by competent authorities will include problems of increase; those of interest to the beginner as well as some new topics involving the production of colonies during the winter, by Mr. Whitten, of Hartford; the maintenance of bees in buildings for school and other purposes.

Mr. Pettit will doubtless speak concerning Ontario beekeeping conditions, giving an illustrated lecture in the evening, I expect.

Amherst, Mass., May 19.

B. N. GATES.

The equipment mentioned by Dr. Gates, which we shall use for illustrating the modern methods for taking extracted honey, will consist of a power honey-extractor, capping-melter, steam uncapping-knife, honey-pump, and all complete.

We might add further that there is a possibility and even a probability that J. E. Crane, of Middlebury, Vt., will be present also. Mr. Crane is a champion of the new method of shipping comb honey in paper cases. He will doubtless be present to illustrate not only the case made of corrugated cellular paper, but how the honey is packed therein.

THE MOTH-MILLER SOMETIMES A BLESSING IN DISGUISE.

INSPECTOR MORRIS, who called at Medina to inspect our bees, called our attention to the fact that the moth-miller is not altogether an unmitigated nuisance. This pest seldom bothers the professional or up-to-date beekeeper. It is only the slipshod, careless, don't-read-the-bee-papers class that it annoys. It is this class who are the early victims of the ravages of foul brood. Their bees become weaker and weaker, and finally die in the winter, leaving combs more or

less filled with honey, and smeared over with the dead matter from foul brood, and, unfortunately, these "old gums" containing infected honey are a constant source of infection to all the bees in their vicinity. The healthy bees within range rob them out. In the mean time the moth-miller, if present, gets in its work, and destroys the combs so that no future swarm will find these old hives a suitable abiding-place. It is right here that the moth-miller proves to be a blessing in disguise. These old combs all covered with foul-brood scales would, unless destroyed by some agency, attract swarms; for experience has shown that they are frequently occupied by stray swarms. The bees get nicely started in housekeeping, begin to fill the combs with honey and brood when, lo! bee disease begins to make its appearance. The colony dwindles, of course, dies in the winter, and is again the source of infection to the neighboring bees. They rob it out once more; but if there are moth-millers in the locality they soon destroy these old combs and leave in their place a mass of webs and filth that is so repellent that no swarm of bees will make a home there. Said Mr. Morris, "The moth-miller, after all, may be a friend to the progressive beekeeper in that it destroys one great source of infection—old diseased combs in his neighborhood that might otherwise remain in bee-trees and old boxes for years and years, and for years and years spread bee disease."

The coyote is a nuisance to the western ranchman because it destroys his young stock; but that same coyote is a blessing in disguise, in that it keeps down the jack rabbit that destroys the same ranchman's crops. There is a beautiful balance in nature when left undisturbed. It may be that the all-wise Creator has created the moth-miller to protect the up-to-date beekeeper.

RECENT FOUL-BROOD LEGISLATION IN THE UNITED STATES.

WITHIN the last three or four months eight different States have passed foul-brood laws. Some of them have had old laws that were defective, while others have secured for the first time legal means for the suppression of bee diseases. First among the list was Pennsylvania. It already had a law but no appropriation. This has now been secured, and Pennsylvania will now take her place among the States that have an effective foul-brood law. The administration of the law in Pennsylvania will be in the hands of Dr. H. A. Surface, Vice-president of the National Beekeepers' Association, President of Pennsylvania State

Beekeepers' Association, and State Economic Zoologist. Dr. Surface is eminently the man for this work.

Michigan is another State that has already secured foul-brood legislation. Particulars concerning this were given in our last issue. Minnesota has now secured one of the best laws that there is on the statute-book of any State. This measure was passed recently, carrying with it a special appropriation of \$3000 a year. At a called meeting of the Minnesota Beekeepers' Association, May 5, a motion was duly made and unanimously carried, recommending the Board of Regents of Minnesota to appoint Dr. L. D. Leonard to the head of the Apicultural Department at the Agricultural College. Dr. Leonard is one of the influential beekeepers of Minnesota. For many years he was president of the Minnesota State Beekeepers' Association, and has been for four years its secretary. He has been keeping bees for twenty years, and in every way is well qualified to fill the post for which he has been recommended.

Iowa has for a year or so back had a foul-brood law, but practically no appropriation back of it to carry it into effect. This defect has been remedied, and now the beekeepers of that State have \$1500. The administration of this law has been placed in the hands of former State Foul-brood Inspector Frank C. Pellet. Another bill has been passed forbidding the shipment of diseased bees into Iowa. Mr. F. C. Pellet is not only a beekeeper, but is on one of the lecture-bureau courses for a variety of subjects. Of course this means that he will be able to give public addresses on bees.

For years California has had a foul-brood law; but, like all county laws, this, to a great extent, has been ineffective. It soon became evident that a State-wide law was needed. For a number of years back the beekeepers of the Golden State have tried to secure such a law, but without success. One has now been enacted that is probably equal to any law in any State. It appoints a commission consisting of the State Commissioner of Horticulture, with the president and secretary of the State Beekeepers' Association. It is the duty of these gentlemen to appoint a State apiarian, who, in connection with the commissioners already mentioned, are to make examination of inspectors in order that no one be appointed who is not well qualified for this important work. It will be remembered that the State Commissioner of Horticulture is none other than our old friend Prof. A. J. Cook, formerly of the Michigan Agricultural College, and later Entomologist at Pomona College, Claremont, Cal. He has ever sought to ad-

vance the cause of beekeeping. He was largely instrumental, if we are correct, in securing Michigan's first foul-brood law. He conducted a number of interesting experiments at the Michigan Agricultural College, showing the invaluable service performed by the bees in pollinating fruit-blossoms. He was among the first to call attention to the value of honey as a food, showing that it is an invert sugar and easily assimilated. He continued his interest in bees when he went to California. He is a big broad man, and we should imagine that conditions respecting bee diseases will be materially improved.

For several years back the beekeeping industry in Nevada has been growing at a rapid rate; but, unfortunately, there has been no effective foul-brood law to prevent the spread of disease. Bees have been brought into Nevada and California by the carload. In many cases it has been found that these carload shipments have contained bee diseases; but the beekeepers of those States were powerless. Nevada has finally come into line, but, unfortunately, with nothing better than a county law. This, however, is much better than nothing; but it is to be hoped that the beekeepers of that State will see to it that a State-wide measure is enacted, as it would be difficult to prevent the importation of diseased bees from diseased apiaries unless some police authority be vested in some State official.

Mr. J. Benjamin Hall, with the co-operation of the beekeepers of Idaho, has just succeeded in getting a foul-brood law enacted, known as House Bill No. 295. A good appropriation was also secured so that good work may be expected. See Mr. Wesley Foster's comment in his department on another page.

Last, but not least, Texas has finally passed the amended foul-brood law, and the same will become effective July 1. Its administration, as before, will be in the hands of the State Entomologist, Prof. Wilmon Newell, at College Station. Prof. Newell is one of the best entomologists in the United States; and, what is more, an enthusiastic beekeeper himself. The biggest State in the Union, and, possibly and probably, the biggest bee State, ought to have a good man for the administration of this law, and it surely has got him. The special features of the new law will be given later.

All together, foul-brood legislation is advancing at a rapid rate in the United States, and we now have 33 States having foul-brood laws. In most of the States the spread of diseases has been checked. In many others there is a decided decrease in brood diseases.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

A BEGINNER might understand from a footnote, p. 140, that a certain size of section may be found that will average a pound. I don't think the editor means that, for there is no such size. If you find a super filled with sections of such size that they average just a pound, you may find another lot filled at the same time by another colony with different average. With the same colony you may find the average different in different years, or in different times of the same year. [You are correct regarding different colonies.—Ed.]

I'M glad A. I. Root is taking up the clothing question. But why not tell us where those Florida shoes can be had, and at what price? But I'm more interested in women's fashions. If I understand correctly, freak fashions are gotten up in Paris—fashions that self-respecting French women will not wear—and foisted upon American women as the proper caper. Thank the good Lord, a rebellion has begun. A. I., have you noticed lately the fashions in *The Ladies' Home Journal*? It will do your heart good to look them over—genuine American fashions, and to me they look beautiful beside the outlandish things that bring high prices merely because *imported*.

O. L. HERSHISER has made out a strong case against extracting unripe honey, p. 177. He's right. But he may not feel so much like condemning Mr. Hopkins' views if he takes into consideration the difference in conditions in this country and in New Zealand. Here, nectar is counted good if it contains no more than 75 per cent water. *In New Zealand, nectar, when first gathered, is generally thick enough to pass for honey under the United States pure-food laws.* Mr. Hopkins says, *American Bee Journal*, 92, "When first gathered, nectar rarely contains more than 25 per cent of moisture, and usually much less." If the two men were to change places, they might change views. Matter of "locality" again, you see.

B. O. MARTIN, p. 180, I think you are right in saying that bees which become queenless accumulate pollen before becoming queenless, *if* it is a case of a virgin lost on her bridal trip. I think Mr. Holtermann is right in saying that when bees lose a laying queen they accumulate pollen *after* the loss of the queen. In both cases there is precisely the same thing, as Mr. Holtermann says: "The bees gathered pollen, and did not have larvæ to feed the pollen to, and it

had, therefore, accumulated in the combs." For, so far as brood was concerned, the colony with a virgin was the same as a queenless colony. You ask, "Did you ever examine a colony that had just lost a queen? and did you not find the combs full of honey and pollen?" and then you limit the question to the exceptional case of a virgin lost on her wedding-trip. Ask that same question without any limitation and the answer will be, "No, not if the queen had been doing good work at laying right along."

Try the thing in this way: Go to a colony with a good laying queen and no accumulation of pollen, and kill the queen. Look two or three days later, and see if there's any accumulation of pollen. Not a bit; for there has been as much brood to feed as if the queen had continued laying. But go two or three weeks later, and see if you don't find the extra pollen.

YOU SEEM to think, Mr. Editor, that half a cubic meter of air is rather small for a 13-pound colony to use in an hour, p. 204. Let's see. At that rate, in a room 10 by 10 and 8 feet high two such colonies would smother inside of 24 hours. Seems to me that's using some air. You're just right, that in a nearly dormant condition they'd use much less. My guess would be not a twentieth as much. [We did not mean to imply that the limit of a cubic meter of air per colony in an ordinary bee-cellar would kill the bees, for, as a matter of fact, a dozen men all smoking can exist in a small room, overheated, with practically no ventilation, for several hours. But it is hard on the men, just the same. If we were to put a colony in a glass bottle, assuming that it could be done, having an internal capacity of a cubic meter, and seal it, we believe such colony would be dead in a very short time, even if the temperature surrounding the bottle were kept down to 45 degrees. The fact is, in an ordinary cellar there would be constant ingress and egress of air. There is usually space around the windows and doors that let in considerable air, especially if the temperature outside is 25 or 30 degrees lower. The oxygen in ordinary air would have to be almost completely exhausted before suffocation would ensue. Perhaps it would pay us next winter to make a metal box a meter long, wide, and deep, and see how long a colony would last in it. We would expect them to boil out of the entrance of the hive and die inside of half an hour.—Ed.]

Beekkeeping Among the Rockies

WESLEY FOSTER, Boulder, Col.

COMPENSATION FOR COLONIES DESTROYED.

Mr. Chadwick makes a good point when he says that colonies of diseased bees should not be destroyed unless the owner is compensated, and I believe that there are cases where this compensation should be made. However, there are many extensive beekeepers whose bees continually have foul brood who think it is a good thing to have a little around to kill off the other fellows' bees. These men ship bees to some extent too. If I have a hundred colonies of bees, and half are affected with foul brood without my knowledge, how long will it be before I have no more bees? About a year, I should say, unless there happen to be good honey-flows. Suppose I move these bees to another State, and they are inspected and destroyed. Should I be paid for what I shall soon lose any way? Or should I be made to suffer the loss and build up on a firm basis of knowledge of foul brood? The best plan would be some quarantine method by which I could save my bees and learn to cure foul brood at the same time. Beekeeping extension carried to its proper conclusion will make bee inspection practically unnecessary.

* * *

THE NEW IDAHO LAW.

Idaho beekeepers have a new apiary bill before the legislature that has some good features, and some that are not so good. It deals with shipments of infected bees from other States in this way. The inspector is to be notified before unloading and not after. A fine of \$250 to \$500 is provided for failure to notify the inspector of the arrival of an infected shipment within five days. A fine of \$100 to \$200 is provided as punishment for selling or offering for sale diseased bees or exposing diseased material in the apiary.

The examination of bees before unloading is a good point; but a quarantine yard should be provided for in these cases, so that the colonies could be treated and cured without having to be shipped out of the State. The fines provided are too high to be of any use. Five to one hundred dollars would be better. One hundred to two hundred dollars as fine for exposing diseased material in an apiary is impractical, for such fines will never be imposed, and they will not have a tendency to better conditions in cleaning out foul brood in a district. More work and educational effort along the line of foul-brood instruction will bring better results. The aim of foul-brood legislation should be to clean out the disease, or

at least to control it—not to fine some one for neglect. Many of us are neglectful.

* * *

THE COLORADO AGRICULTURAL DEMONSTRATION TRAIN.

The honey-cooking recipes are the most popular part of the bee-culture exhibit on the Colorado Agricultural College demonstration train. Mrs. Frank Rauchfuss prepared the goods, and they are so appetizing and toothsome that every lady passing the exhibit wanted to stop and copy the recipes printed on the jars containing the samples. We soon realized that this would clog the traffic through the car, so 3000 copies were run off on the multigraph and given out.

HONEY RECIPES BY MRS. A. RAUCHFUSS. HONEY BROWN BREAD.

One cup corn meal, 1 cup rye meal, 1 cup sour milk, ½ cup honey, 1 teaspoonful salt, 1 teaspoonful soda. Steam 4 hours, then dry in oven 15 minutes.

AURORA HONEY COOKIES.

One cup honey, 1 pint sour cream, 1 even teaspoonful soda dissolved in a tablespoonful of boiling water. Mix honey, cream, and soda together thoroughly; add a cup of chopped nuts (any kind desired), 1 teaspoonful of ground ginger, and a heaping tablespoonful of ground cinnamon. Add flour enough to make a dough stiff enough to handle easily on the board; roll out part into buttered tins, and bake in a moderately hot oven until nicely browned.

HONEY GINGER SNAPS.

One cup butter, 1 cup sugar, 1 cup honey, 1 cup water, 1 heaping tablespoonful of ground cinnamon, 1 scant teaspoonful of baking soda. Sift the soda into 1½ pints of flour; cream the cup of butter with the sugar; add other ingredients, and more flour to make a dough that can be rolled out. Cut into desired shape, and bake in a moderate oven.

SEAFOAM CANDY.

Two-thirds cup of honey, 3 cups granulated sugar, ½ cup boiling water, whites of two eggs, 1 teaspoonful vanilla, 1 cup of nut meats. Boil the honey, sugar, and water till, if tested in cold water, it is brittle. Pour this in a thin stream over the whites of two well-beaten eggs, beating the whole all the time till like a thick cream, then stir in briskly the nut meats and vanilla, and pour out into a buttered dish. After it has hardened, cut into squares.

With one week still unfinished, over forty thousand people have seen the exhibits on the train. Ten lectures on beekeeping have been given, and much interest has been manifested, as is shown by the questions asked. The questions most frequently heard are about the control of foul brood and swarming. Amateurs surely have trouble in the prevention of excessive swarming. Many report that yellowjackets kill their colonies; but so far it seems that this occurs only where excessive swarming has been the rule throughout the summer, and none but weak colonies short of honey and with the hive but partly full of comb to go into winter quarters. It is no wonder that colonies are soon cleaned out by the yellowjackets.

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

This year, again a number of "apiary demonstrations" are being held in different counties of Ontario. This style of giving instruction in apiculture seems to be rapidly superseding the old-style meetings; for to the average student one ounce of "show me" is worth a pound of instruction of certain manipulations of the bees.

* * *

I do not agree with friend Townsend at all when he says in regard to American foul brood, "Once in a locality always in a locality," as I am sure we have many places here in Ontario that were once badly diseased that are now clear. As to European foul brood, while we have not had the actual experience in our own section yet, I suspect he would be more nearly right if he applied that saying to this disease.

* * *

My intentions are to leave home on May 14 and move 250 colonies of bees, with about 500 supers and other supplies, three miles to the railway, and then 200 miles by train. In addition to this I have to make by mail all arrangements for moving, as I am now 200 miles from the bees. Now, don't all speak at once and say that you envy me the job, else I shall suspect some are hardly truthful in what they are saying.

* * *

In giving the Demaree plan of keeping down swarming by hoisting all brood-combs but one above the queen-excluder, please sound a note of warning to beginners that, unless they are very careful, they will have a lot of dark honey in those brood-combs, and the honey will be all off grade when they are ready to extract. The seasons are rare in this "locality" when *all* the dark honey will be out of *all* the brood-combs when the clover season starts; and for that reason the plan of hoisting all brood-combs above is impractical here, much as we might desire to practice the plan, for it assuredly will knock out swarming if properly done, and give a maximum in the way of a honey yield.

* * *

Also make the "warning" very pronounced when advocating the Alexander plan of making increase, and say that it is advisable to use this plan only in localities having their main flow late in the season; for I agree with Dr. Miller most emphatically in saying that, for clover locations, the plan is no good unless one wishes to cut the crop in half. This year our bees are very strong, many having to be supered in willow bloom,

even if the bees are in ten-frame Jumbo hives; and yet under such conditions I would not think of breaking up the colonies unless I were willing to sacrifice part of the crop of clover honey.

* * *

Reports continue to come in, that the spraying law is being violated this year a great deal, and many beekeepers are fearful that much damage will be done to their bees. As pointed out in a recent issue, the fine is very low, and many operators openly say they can afford to pay the fine rather than stop spraying operations when each day's work means about \$15.00. Then, again, many beekeepers hesitate to apply the law to neighbors, even if the fine is low, as hard feelings always follow a lawsuit. Something will have to be done in the near future, especially in the commercial fruit-growing districts, as the situation is becoming very acute indeed.

* * *

When sending that protest to Miss Tarbell regarding that glucose-honey-comb canard (page 281, May 1), please send another protest to the chaps who are advocating making queen-cage candy with glucose. Yes, I admit that I recently expressed the hope that honey could be left out altogether in making Good candy for mailing queens, for the queen-breeders' sake; yet I now see that the remedy would be worse than the disease. First thing you know, you will see a big advertisement in the *Ladies' Home Journal* or some other big influential magazine, telling us that even *beekeepers* recognize that glucose is better than honey, and are using it to feed their queens. In a case of this kind, it is better to avoid the very appearance of evil and be on the safe side.

* * *

The latter half of April was very cold and windy, with heavy freezing by night and thawing by day. Result, fully half of the alsike is killed outright here in York Co. We should be thankful that there was a heavy acreage, as we still have lots left for a crop of honey if clover should be in nectar-yielding humor. Flat fields suffered most, because there has been an unusual amount of moisture in the ground. Clover-killing was only local. Most localities report that clover is in good condition. The season for fruit bloom is one of the earliest on record, for winter jumped abruptly into the arms of summer about April 25. Good reports of the bees are coming from all over Ontario, so, needless to say, Ontario beekeepers are hoping for the best this year.

Conversations with Doolittle

At Borodino, New York.

IS NATURAL SWARMING PROFITABLE OR NOT?

There is not a shadow of doubt in the mind of the apiarist who makes a specialty of beekeeping but that he would be much better off if bees never desired to swarm; but with the beginner or the farmer beekeeper there is an element in natural swarming that appeals to him, and to all there is a certain awe and fascination on seeing a natural swarm of bees on the wing. I have heard expressions of wonder and admiration come from the lips of all sorts of men and women when seeing a swarm of bees in the air. One of the great things about a natural swarm of bees, and one which can hardly yet be denied, is this: The bees of a natural swarm receive an impetus to work by finding themselves in their newly pitched tent destitute of brood and provisions, not brought about in any other way. Then if the sections are put over such a swarm as soon as the bees are nicely established in the hive (to an extent where the queen has begun to deposit eggs in the newly built comb or drawn foundation), section honey can be obtained which is rarely if ever equaled by any of the processes of artificial increase yet invented by any apiarist or by any plan of non-swarming.

That there are some weighty objections to natural swarming if it could be successfully repressed is not to be denied; but these may be spoken of under two heads—namely, the time and labor required for watching and hiving swarms, and the danger of loss from swarms absconding. It may be held by some that an undesirable increase would be the greater objection; but with the practical man this should be easily obviated, even to a point of value. If all swarms are to be hived in empty hives, as was the case with those keeping bees fifty or one hundred years ago, then I will concede the point; but with the one who has twentieth-century light it is only a question of the disposal of the brood in the hive from which the swarms issue, and that is generally very valuable, especially in early swarming. Some seem to think that this brood, when emerged into perfected bees or before, should be returned to the identical colony that produced it; but with the practical apiarist it may usually be used with decidedly greater advantage in other ways.

There are few if any apiaries at the opening of the nectar flow but that have some colonies that are not up to the strength required for the best work in the supers. If these hives of rapidly emerging brood be

distributed among such deficient colonies as fast as they can be obtained from the leaving of prime swarms, shaking out of each all of the bees left behind so that they may go into the new hive with the prime swarm, both the swarm and the deficient colonies will be greatly benefited. Thus in a week or two, if swarming continues, all may be gotten in excellent condition, and results obtained beyond the fondest expectations.

Then, too, there are frequently colonies out of condition on account of being possessed with wornout or old queens. Destroy these queens as fast as hives of brood can be obtained, and place one such hive on each colony now queenless. In a few days it will rejuvenate in strength, and will have an extra-good queen coming from the queen-cells left after the issue of the prime swarm.

The danger of loss from prime swarms absconding can almost certainly be prevented by having the wings of the queen previously clipped, which is most conveniently done in May when the fruit-trees are in bloom. Then, as soon as the swarming bees miss their queen, they may be made to hive themselves by having the new hive on the old stand at the time they begin to return. Some claim that, should a swarm come out having a virgin queen at the time such prime swarm is clustered or in the air, said virgin queen would make absconding possible, she having her wings to fly away with the whole mass. But after forty years' experience in this matter, with scores if not hundreds of such cases, I wish to go on record as saying that, so far as I know, the bees of a *prime* swarm will never be satisfied with a *virgin* queen to lead them away from their old mother or the hive of brood which is left behind. Such uniting results in the balling of the virgin, when the whole mass, except the few in the ball, are practically queenless.

The objection made against swarming on account of the time required for attending to it is not great where the apiary can be located within easy vision of that part of the house where the kitchen work is done, as most prime swarms issue between the hours of nine o'clock and one, when the housekeeper can notify the apiarist if he himself is not at work in the apiary. For the highest success in the production of section honey, strong swarms are desirable; and hiving swarms on the old stand and giving them all the bees which the parent colony contained not only conduces to their strength, but prevents that greatest nuisance, the call of "bees swarming."

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

A beekeeper expressed the foreboding that it would be very difficult for the professional apiarist to protect himself from the ravages of black brood with so many uncared-for colonies to contend with. I take a different view of the situation, for it is my opinion that, after a locality is infected with the diseases, there will be a few of the truly watchful and painstaking with the field practically to themselves.

* * *

The foul-brood law proposed by the State Association was passed with only one or two unimportant changes. It carries an appropriation of \$10,000, which amount is not to be used for general inspection work, but each county must still pay its own inspector, though the appointment and dismissal are almost entirely at the will of the beekeepers. I believe that we now have the best foul-brood law in the United States. Inspectors will hereafter be appointed on merit, and not to pay political debts. Inspectors will not be able to draw 16 to 20 dollars per month during the winter months for office time, but will have to "produce the goods" or get out. If the State Association has accomplished nothing more, this alone is worth all the beekeepers have paid into the treasury. A copy of this law will appear in these columns later.

* * *

MIDDLEMEN CONTROLLING PRICES IN SPITE OF THE LAW OF SUPPLY AND DEMAND.

Dr. Miller, p. 172, speaks of the women of several large cities taking a hand in the egg market and reducing the price to a point where they could be purchased by the poor, also the apple market in Chicago, and thinks the farmer received no less for the produce on the market at the time. The doctor is, no doubt, right so far as the produce involved was concerned; but when it came to restocking the market for the next raid, the dealer would take into consideration this very feature of the situation, and pay prices accordingly. When such means are used to reduce the price on produce in storage, purchased at a low figure, it may work all right; but when it comes to a market controlled wholly by the supply and the demand, the result would be that the farmer would get the worst of the deal. About the only way this situation can be met is to make it easier and cheaper for the farmer to get his produce to the consumer—not to the dealer, but to the consumer's kitchen, and that seems to me to be

the only way it can be done; for if it passes through the hands of one or two middlemen there is too much temptation to combine and fix prices, as I am told has been the case in Los Angeles for a number of years. There the supply has very little to do with the market. The price is agreed upon by the retailers; and if the supply is larger than the trade demands at the price fixed they are dumped to clean up the oversupply, and the grower is paid a price that will enable the dealer to carry on this kind of wasteful business. Many a poor child might enjoy the pleasure of a dish of berries if the price followed the supply instead of the berries being destroyed to maintain an arbitrary price that does not help the producer.

This matter will be given attention by our legislators some day, and I should not be surprised if the national government would be the first to take the matter up after they find it can not be done by tariff laws, which are to a great extent local in nature. Transportation rates reduced to a reasonable figure would be of more benefit to the American people than all of the free-trade or tariff laws that can be devised, if middlemen's profits were reduced in a like manner or eliminated almost altogether. The middlemen have to live, to be sure, but not in this particular line of work; for the time is coming in this land of ours when more men must be producers and fewer live on the work of those who do produce. This applies to the bee business as well as any other agricultural pursuit.

* * *

SUDDEN DROP IN TEMPERATURE KILLING FIELD BEES.

There is one condition that I believe I have never mentioned in these columns, that affects the early spring honey crop perhaps more than any other; and that is, the mortality rate of field bees. California seems to have a cause that is peculiar to this climate. The loss of which I am speaking is due to a sudden change in the air from warm to cold while the bees are in the field, which causes them to become so numb that they are unable to reach the hive. In connection with this I may say that our fine climate is due more to the sunshine than to any other one thing; and without the sunshine we have just as cool and chilly days as are found in New Jersey or any other eastern State during the spring months. Indeed, variation in temperature between

day and night would cause an Easterner some uneasiness for fear of frost, for a change in temperature between day and night is often from thirty to forty degrees. It is not at all uncommon for the temperature to fall at this time of the year from ninety degrees at midday to forty by four o'clock of the following morning. It can readily be seen from this that bees must wait until after sunrise on many days before the air is sufficiently warm to permit them to venture into the field. But the condition just spoken of does not necessarily cause loss of bees. Fog is one feature that causes heavy loss. By this I do not mean the low dense fogs, but the high fog clouds that drift over the sky the greater part of many days, which become denser in the early afternoon. Then, again, the intermittent cloudy days following a storm flurry bring conditions that are equal to any bee-trap that was ever invented. The sun comes out for perhaps twenty or thirty minutes, which gives the bees reason to pour into the field by the thousands, when suddenly a cloud floats over, obscuring the sun, and perhaps it remains there for an indefinite time, causing the bees to chill in the field to such an extent that they are unable to take wing and return to the hive. The sun sometimes shines enough to warm them and enable them to return; but the number of times that they are unable to go back is sufficient to deplete the field force so that it is very noticeable in the numerical strength of the hive. These conditions prevail more or less every spring; and until the weather becomes more settled, there is a constant drain on the forces that are so much needed at this time of the year.

* * *

A DISAPPOINTING SEASON.

This will, perhaps, be my last report on crop conditions in this part of the State for this season, for there will be no crop. This is the most complete failure for many years, and I doubt if it has a parallel in the history of the industry here, though of this I am not sure; but that it is the nearest to a complete failure for ten years I am quite sure. Why? Every thing has been against us from first to last, and conditions are not yet what might be called normal. Of all the reasons for a failure, the lack of rain is the chief cause, with the freeze and an unusually cold spring to contend with, though I consider the freeze to be the least of our troubles. Conditions seemed bad from the beginning; but the bees got a fairly early start at breeding, and this gave a ray of hope for a time. However, the loss of bees from some cause was so great that even

those with a good supply of brood failed to make the progress that we had hoped for. For example, on March 1st, in marking my colonies I came to one with two frames of brood which was marked 2. Two weeks later it was the same; but by the end of the third week they had spread to four frames, and there they have remained since that date. They have spread eggs wider several times, but they have been taken up because of being chilled or by choice of the bees under the influence of continued cold.

Another cause in the orange districts was the early blooming, in spite of the cool weather before the bees were ready to gather the nectar, the heaviest flow being almost to a day one month earlier than last season. My scale colony showed the heaviest day this year on April 25; last season it was on May 23. The quantity of nectar and the short blooming period were also a disappointment. So the season of 1913 must pass into history as a failure so far as a honey crop is concerned in southern California, with the fact remaining that we must not expect a crop from wild flora when our rainfall has been much less than ten inches, with a goodly portion of that falling late in the rainy season.

I will give the weights of my scale colony for a period of two weeks, a part of which time was the warmest during the month of April, and will show the weather variations by the amount gathered each day. Previous to the time I began taking weights we had several days of fair weather. (By fair weather I simply mean days when it was sufficiently warm for the bees to fly very freely during the greater part of the day. We have had many days that were clear; but a cold wind and a low temperature made short days and difficult flying the peculiarities of this season.) Before placing this colony on the scales the bees had stored some honey in the extracting-super, which also contained a quantity of brood in addition to that in the well-filled brood-chamber. (The hive was overflowing with bees.) The queen was put below an excluder, and a super of extracting-combs was placed between the two. The following are the daily gains: April 16, $\frac{3}{4}$ lb.; 17, 2 lbs.; 18, $\frac{1}{2}$; 19, $5\frac{1}{2}$; 20, $2\frac{1}{2}$; 21, $6\frac{3}{4}$; 22, $6\frac{1}{4}$; 23, $8\frac{3}{4}$; 24, $9\frac{1}{2}$; 25, 10; 26, $7\frac{3}{4}$; 27, 8; 28, $6\frac{1}{2}$; 29, $7\frac{1}{2}$; 30, $2\frac{1}{2}$; May 3, $3\frac{1}{2}$. The variations to this point are due almost entirely to weather conditions. The above figures are gross amounts, no allowance being made for evaporation during the night, which varied largely according to the quantity gathered, and was from $\frac{1}{2}$ to 3 pounds.

General Correspondence

A NEW METHOD OF INTRODUCING

The Various Methods Considered; the Odor Theory—is it a Fallacy?

BY ARTHUR C. MILLER

Legion is the number of plans for introducing queens, and he is a rash man who claims to have found a new one; and yet perhaps the unexpected may have happened here.

The "direct method" was the first one used; and, if memory serves, Reaumur was the man who used it. It was years after he had passed away that the caging plans arose. Who began them may perhaps never be known, for, like Topsy, they seem to have "just growed." But growing and spreading and varying as they have, they have by no means brought satisfactory results; on the contrary, so great is the loss by all cage methods that the beekeepers are few who are not looking for a better way. All of the cage plans are based on the theory that the odor of the queen governs her reception—that is, if she is confined in a cage placed in the colony to receive her until she has acquired the hypothetical odor of that colony she will be safe when released. But, as all experienced beekeepers know, too many times the facts do not prove the theory.

ODOR NOT THE GOVERNING FACTOR IN INTRODUCTION OF QUEENS.

Colonies do have individually characteristic odors, some of which are such that the human nose of fair acuteness and training can detect them. If the human nose can distinguish between certain colonies, then surely the bees, with their wonderfully acute sense of smell, must be able to distinguish between their own and a strange hive. But because the individual bee can recognize the home by odor, it by no means follows that the colony can recognize the individual worker by her odor. On the contrary, when the bees of an apiary get to work on any particular kind of flowers, whether clover, basswood, buckwheat, or other flowers, the bees mix freely. To illustrate: In an apiary of thirty odd colonies there were three distinct and easily recognized strains of Italians and one of blacks. The season until mid-July was poor, the bees getting but little more than a living. An examination of the colonies then showed very few bees in them that were not raised there. There followed a heavy flow from *Clethra*, and within a week every colony had a very considerable part of its population made up of all the different strains. Had the bees' sense

of smell gone wrong? Or is the odor factor of less importance than we have given it?

DIRECT METHOD OF INTRODUCTION.

For many years the writer has used some form of direct introduction with queens, and only occasionally has used a cage. In the beginning the "fasting plan" was carefully followed; then, little by little, it was modified and changed, until ultimately all sorts of ways were used for running in the queens. The system which he now uses most of the time, and which never fails, is as follows: A colony to receive a queen has the entrance reduced to about a square inch with whatever is convenient, as grass, weeds, rags, or wood, and then about three puffs of thick white smoke—because such smoke is safe—is blown in and the entrance closed. It should be explained that there is a $\frac{7}{8}$ -inch space below the frames, so that the smoke blown in at the entrance readily spreads and penetrates to all parts of the hive. In from fifteen to twenty seconds that colony will be roaring. The small space at the entrance is now opened; the queen is run in, followed by a gentle puff of smoke, and the space again closed and left closed for about ten minutes, when it is reopened and the bees are allowed to ventilate and to quiet down. The full entrance is not given for an hour or more, or even until the next day.

The queen may be picked from a comb and put in at the entrance with one's fingers, or run in from a cage just taken from the mails, her attendants running along too. The result is the same. The alien queen and workers are quite as much at home as the real owners of the hive. It makes no difference how long the colony has been queenless, whether just dequeened, or so long that laying workers have infested it.

Right here two conditions should be cited, or beekeepers not familiar with bee behavior may sometimes experience trouble. Colonies with sealed queen-cells or with virgin queens will sometimes supersede the new queen, particularly if that queen has been kept from laying for some days prior to her introduction. A queen taken fresh from the combs where she is laying freely will generally cause the destruction of the cells or the virgin. Different strains of bees and different colonies of the same strain behave differently toward a plurality of queens, or queen and cells. For example: A good populous colony late in September had been dequeened, and had built half a dozen or more queen-cells, most of which were allowed by the bees to hatch. October 14, ten

days after the cells hatched, a virgin queen was removed, and a fertile queen, which had been caged for 48 hours, was run in. The next day the fertile queen was moving quietly over the combs as was also another virgin. The bees had tolerated for ten days a plurality of virgin queens, and later a fertile and a virgin queen. Of course, this is somewhat unusual, and may partly be due to the lateness of the season, breeding having stopped in most colonies.

To colonies long queenless—particularly if suspected of having a virgin queen—it has been found advantageous to give a comb with eggs and young larvæ just before running in the queen. Queen-cells may be looked for and destroyed or not; but so far as the writer has experimented it is not necessary to destroy them, the bees attending to that. If, however, the colony is populous, and the honey is coming freely, a swarm may result if the cells are not destroyed by the beekeeper. More exhaustive observation is needed in this line, however, before it is wise to make positive statements. But with a virgin present, the giving of eggs and larvæ will almost invariably cause his disappearance. And it is impossible to ensure the safe introduction of a virgin to a colony having eggs and larvæ.

The loss of virgins in introducing is due either to the cause above cited or to their running out. To prevent the latter trouble it is found best to run in the virgins near nightfall, when all the bees are in, and then plug the entrance with a leaf or leaves. By morning the leaves will have wilted so the bees can get out, and matters will proceed normally.

It is the writer's preference, in introducing laying queens, to dequeen the receiving colony immediately before running in the new queen.

The theory of the cause of the success of the "direct method" here described is this: Bees in distress, whether workers, drones, or queens, know no enemy or alien, and each one is turning to some other for "help" or food, and every bee which comes within the influence of the uproar of a distressed colony seems to be seized with the same emotion. The bees with the queen in the cage, as soon as they are placed at the entrance, evince every sign of the same disturbance as shown by the bees of the colony, and it takes but a gentle puff to send them in.

The closing of the entrance after the queen is in is to ensure the distressed condition throughout the entire colony, and keeping it closed for the ten or fifteen minutes is to prevent too speedy relief. Then, too, if the full entrance were opened, the

bees might pour out in a mass, and cause bother; whereas by opening only an inch, few rush out before systematic ventilating is taken up.

The inexperienced and the thoughtless need to be cautioned as to two things, namely, closing in a full colony without giving the bees room to spread into and get off from the brood, and closing in a full colony sitting in the sun in the middle of a sweltering day. The skilled bee-master can do both of these things; but he does not do either of them if it can be avoided. And when he does do them, he stays right on the job, keeping eyes and ears open. The inexperienced should also be warned against running virgins into full colonies and closing them for over night. It is poor policy to give a virgin to a full colony at any time. It is much better practice to mate the young queen from a one or two frame nucleus.

It will be well, perhaps, to mention another item in the behavior of introduced queens. It is not unusual to find that a queen which has been given to a colony for some time queenless—say until all larvæ are sealed, or nearly ready to seal—fails to lay, even after she has been in the colony for a week or more. This is particularly so when the queen has been for a long time caged. To start her to laying give the colony a comb with eggs and larvæ of various ages, and with or without the adhering bees. In from 24 to 48 hours the queen will begin work.

The writer has run in hundreds of queens by various "direct methods," and has found the system here described the best. He believes it, as a whole, to be original with him. Its trial by all beekeepers is urged, for it seems to be an easy solution of a much-vexed problem.

It may be contended by the champions of the odor theory that the shut-in smoke imparts a new and uniform odor to the bees of the colony and to the new queen, and that the success is due to that. This is plausible; but the same success can be obtained by agitating the colony by closing the entrance, pounding on the hive with the closed fist until the bees are roaring, and then run in the queen. It is as uniformly successful as the use of smoke, but not quite so quick, and a bit hard on the fist.

Providence, R. I.

[Our correspondent has for several years believed that the odor theory for introducing has been overworked. He is possibly right. It is a fact that can not be denied, that there are several conditions that must be right before successful introduction can be accomplished. We have held that a like

odor is one of the conditions; but it is not the only one. The caging method of introducing is the one commonly recommended by the commercial queen-breeders to their customers. It is simple, convenient, and in most cases it gives good results. In our own apiary it rarely fails. Why do we believe in the odor theory? We may cite a few instances that will help to explain our position:

The ordinary queen that has traveled from a hundred to a thousand miles in the mails acquires a variety of odors that are foreign to the inside of the hive. It is well known that a queen from the mails is harder to introduce than one out of the same yard, especially if the latter is introduced while in the height of her egg-laying from a vigorous colony. The odor of a fresh-laying queen is an important factor in successful introduction. The bees know that she has been recently at her job. Indeed, she has so much of the general colony odor that they may not know that a change of queens has taken place. In this connection we recognize that there may or may not be a specific colony odor; but we believe there is. We will refer to this later.

Now, then, the object of caging a queen just from the mails, before letting her loose, is to let her get rid of the variety of odors foreign to a hive, and at the same time let her acquire a general colony odor. The object of caging is not alone for the purpose of getting the odor right, but for the purpose of letting the queen get out of her confinement quietly and without disturbance. When the queen and the bees eat out the candy, she works herself into the presence of her subjects so gradually and so easily that there is no disturbance, and she begins her duty shortly as if nothing had ever happened. The object of caging then is for a twofold purpose—like odor, and entrance into the colony without disturbance.

We have recommended the caging in preference to the various methods of direct introduction because we believe that the average beginner will succeed better with them. The method described by our correspondent may be better, but requires an exact procedure, some details of which the average novice and some veterans might inadvertently omit.

A little way back we spoke of the importance of a like odor in a colony. We have for years practiced what we call dual and sometimes plural introduction—that is to say, there may be two or more virgin queens caged at the same time in a nucleus. Virgin No. 1, caged first, will be released. If ac-

cepted she will soon be laying, when she will be removed and No. 2 is released. She has been in the hive or nucleus for several days; has the same odor as the queen just removed. No. 2 begins to lay, when she is finally succeeded by No. 3, and so on the process of caging and removing proceeds. While one queen is getting ready to lay, the other is acquiring the nucleus or colony odor.

Now as to the question whether a colony has an individual odor. We do not know how the inmates of the hive would recognize that the outside bees were robbers unless there were an individual odor to each colony. Again, in uniting, two strains of bees will often fight, sometimes utterly annihilating each other. A little tobacco smoke or even common smoke obscures the distinct colony odor so that all smell alike of tobacco or common smoke. Mr. Miller possibly holds the view that the disturbance arising from the use of the smoke brings on a condition of demoralization that obliterates the fighting qualities. We admit that on this point he may be right. Neither do we say that he may be wrong in regard to the odor theory in the general subject of introducing.

Right in this connection we believe that the plan here outlined by our correspondent for direct introduction by the use of smoke is a good one; but it is our opinion that two elements—odor of smoke and disturbance—make up a *combination* that insures the success of the plan, although we admit that either one alone would be sufficient in most cases.

There are several interesting facts that Mr. Miller brings out in his valuable article to all of which we give assent, except that we attach more importance to the odor theory than he does, and at the same time we believe that the caging plan for the novice is the safer one to follow. The average beginner might make the mistake of closing up a colony over-populous on a very warm day, and that would make trouble. It is a little difficult to tell him when he may and may not do this. But almost anybody can follow the directions to lay the cage on the top of the brood-nest, and let the bees do the rest.

In this connection we believe the push-in-the-comb-cage plan of introducing would be better than the eat-out-candy plan; but we have hesitated to give it to our customers for fear that they might not get the cage properly adjusted on the comb.

This is a good question for discussion, and we should be glad to hear from others. —Ed.]

IN MEMORIAM OF OLIVER FOSTER

BY WESLEY FOSTER

Oliver Foster was born in Grant County, Wis., March 21, 1857, and died March 12, 1913, at Boulder, Colo. When eleven years of age he moved with his father's family to Mr. Vernon, Iowa, where he grew up and went into beekeeping and queen-rearing while still a young man. His first swarm was hived from a stump near his home when he was fourteen. The year 1879 was the date of his first queen-rearing operations and of the handling of supplies in quantities.

About the year 1881 he invented a comb-foundation press, and he sold a good many of them. Mr. Doolittle wrote him not long ago that he was still using the outfit, and that it was doing good work. The following description of the machine is from his circular printed at the time:

FIG. 1.—The object of my invention is to furnish a very cheap machine to mold foundation directly from melted wax. The mold, AA, consists of two plaster-Paris plates in strong iron-braced frames, hinged together. The melted wax is sprinkled over the right plate by drawing the fountain across and back (the fountain is now made very light). The wax pours from the row of holes as the fountain is drawn back with the handle raised. This is done with the right hand. The mold is closed with the left hand; and the surplus wax, if any, passes into the water in the tank. The fountain is left in the wax while the mold is opened and the foundation removed. As the plates lie in water they are constantly cooling and moistening; hence no soap or other lubricator is needed to prevent sticking. The operation is very easy and simple. I use the best patterns, and make perfect casts every time. One set of casts will make about 200 lbs. of foundation. Some say more. The foundation can be made thick or thin on the same mold, from 5 to 20 square feet to the pound. The very light is made by pressing small thin sheets, say 4 x 6 inches. A lever is used which I "throw in." The foundation is not quite so perfect in form as some; but the bees use it just as well. Full instructions sent with machines. The mold weighs about 20 lbs.; whole outfit, 50 lbs.

Mr. Foster also invented and patented a honey case and clamp made to be used with the four-beeway section. It was designed to give the bees the freest possible communication from top to bottom and throughout the super. Page 450 of "Langstroth on the Honeybee" quotes several paragraphs from his booklet which I am inserting here. It will show that he studied the problem of comb-honey production carefully and was original in his findings.

There should be free communication between the sections in every direction. They should have deep slots on all eight edges so that the bees can pass freely over the combs from end to end of the case, as well as from side to side, and from top to bottom. You may not appreciate the importance of this until you have tried them. When we take into consideration that the object on the part of the bees in storing up honey in summer is to have it accessible for

winter consumption, and that in winter the bees collect in a round ball, as nearly as possible, in a semi-torpid state with but little if any motion except that gradual moving of bees from the center to the surface and from the surface to the center of this ball, we may imagine how unwelcome it is to them to be obliged to divide their stores between four separate apartments, each of which is four inches square and twelve inches long, with no communication between these apartments.

About 1885 he was carefully studying comb-honey production, and the result of his investigations were printed in a little book, "How to Raise Comb Honey," a copy of which I have never seen. If any of the readers of GLEANINGS have a copy I should like to know of it.

In 1894 he moved two cars of bees—180 to 190 colonies—and equipment to Las Animas, Colo., from Mt. Vernon, Iowa. He

The late Oliver Foster, pioneer beekeeper, inventor, and manufacturer.

reached Las Animas in May and harvested about 70,000 pounds of extracted honey that season—the largest average per colony he ever had. This crop was also the whitest honey he ever produced, and did not granulate in the sixty-pound cans for a year—remaining clear and liquid. This is something of a point for alfalfa honey.

The following spring Mr. Foster moved the rest of his bees from Mr. Vernon, Iowa, to Las Animas. His bee-supply and queen-rearing work was given up for extracted-honey production, and he also dropped most of his experimental work.

In 1903 he sold out at Las Animas and moved to California for his health, but re-

turned to Colorado in 1905, locating in Boulder, where he and his family have lived since that time. During his residence in Boulder he did more experimenting, and some of his ideas were of much benefit to himself and to other beekeepers who adopted them.

Throughout his whole life he had to save his strength, never being very robust, and for this reason a great deal of work had to be done by hired help. He has been especially successful in leasing bees to men who have worked under and with him.

At the time of his death he owned and was interested in about fifteen hundred colonies of bees in three different States, five systems of out-aparies, and fifteen locations. His net income from leased bees has been between 12 and 15 per cent for a term of about ten years.

He has belonged to the Methodist Church since a boy, and has filled every position in the Sunday-school, from teacher to superintendent. At the time of his death he was a member of the official board of the First Methodist Episcopal Church of Boulder.

Boulder, Colo.

ANNUAL FIELD DAY OF THE CANTERBURY BEEKEEPERS' ASSOCIATION

BY E. G. WARD

The Canterbury Beekeepers' Association held its annual field day at the apiary of Vice-president R. N. Gidley.* The party went by drag about 27 miles from Christchurch. The weather was very warm, but ideal for the purpose. After being welcomed by the host, lunch was partaken of and

* A picture of this apiary appears on our cover for this issue.—Ed.

Mr. R. N. Gidley, of New Zealand, and one of his best colonies which had stored 227 pounds up to the time the picture was taken.

an adjournment made to the apiary, where the government inspector, Mr. L. Bowman, gave demonstrations in modern methods of handling bees, and answered a number of questions on bee subjects. Mr. Gidley opened some of his best hives, and explained his methods of securing a large crop of honey. During the day the president gave a short address explaining the objects of the Association. He also spoke of the interest taken in bee culture by the government. The necessity for co-operation in the disposal of the crop was touched upon by both Mr. Bowman and the president. Mr. A. Ireland, a past president of the association, also gave an address on similar lines, and on his motion a resolution was passed affirming the principle of co-operation, and leaving

Field meeting of the Canterbury Beekeepers' Association at the apiary of R. N. Gidley, Lakeside, N. Z.

the matter of the formation of a company on these lines in the hands of the executive of the Canterbury Association. A vote of thanks to the host was carried with musical honors, and the party left for home after spending an enjoyable day.

Christchurch, N. Z.

SHIPPING FRAGILE ARTICLES

Some Advice from One who has had Experience

BY JAY W. GEE

Continued from last issue.

The matter of glass in the case has been frequently mentioned in GLEANINGS. I do not believe that the use of glass makes any difference one way or the other, except to weaken the case. The average day laborer on a transfer platform has little time and no inclination to be peering through either a two-inch or three-inch hole in any of the boxes he handles to see the contents. If he be a negro there are two things he always knows from outside appearances—shoes and whisky; and if you don't look out, Sambo is going to have some of both. If one is compelled to ship by freight, the honey should be thoroughly and tightly packed in corrugated paper or something similar to take up shock and vibration in a very strong case; and you can not make them too strong. If you have a carload,

have your agent lend you his instruction-book governing the loading of dynamite, and brace the honey exactly the same as you would for that explosive. In switching, cars get some terrible licks unintentionally. I have seen them hit so hard that you could see them bow up in the middle apparently six inches.

GLEANINGS is against shipping by express, I know; but as the express business will soon be in the hands of the government, perhaps Brother Root will relent. I am just stating my experience. At one place where I was employed for several years I handled the express on commission, having a large transfer to take care of also. After I had been there about two years I had meantime been experimenting with a few hives of bees, and had taken off about one hundred sections of snow-white honey. There was no local sale. In fact, I gave my neighbors all they wanted. The best price that the nearest town offered was ten cents. I had a relative in the Texas Panhandle in a good town, who offered to take all that I would send him, and pay twenty cents. How to get forty or fifty pounds to him was the question. One thing the public as a rule does not know about the express—all employees are under bond, and held strictly accountable for the safe keeping of the property in their care. Every claim that the express pays is traced down to the em-

R. N. Gidley, New Zealand, demonstrating his method of securing a large crop of honey.

ployee at fault, and he is compelled to pay it. There are very few claims that are not saddled off on some one. Hence you may be sure that the express man gives attention to every thing in his care.

In my two years' experience I had noticed that packages received attention in *inverse* ratio to the care with which they were packed. For instance, if I ran across a very strong and well-made box I would pitch it from one end of the car to the other; but if the parcel happened to be a frail hat-box, with the merest strip of crating around it, or a splint basket lined with cotton, and marked "Eggs," I handled it with the greatest care, and so did all the rest, and so they do yet. You can't turn a splint basket over; you can't pile any thing on top of it; and you have to handle it carefully at all times. That gave me my cue. The saloon man across the street gave me several corrugated-paper cartons of the size that he used to ship half-gallon jugs in. Seven sections of honey, firmly tied together with the top sides up, and just a few thicknesses of paper around, made a compact package that exactly fitted in the carton. I then sealed the carton, put some straw in a common five-cent splint basket, and put the carton in it, this also making a snug fit. Then I tied the carton in firmly so that there was no possible chance for it to work loose. Finally I wrote in my ordinary hand, on one edge of the carton, "Honey!

handle with the same care as"—and then in large printed letters that took up the rest of the space of the carton—"Eggs." The object of this was not to deceive, but to be sure that every one handling would see at a glance the fragile nature of the contents. Of course the shipment was billed "1 bsk honey;" and as the entire package weighed just a little over nine pounds, and comb honey, owner's risk of breakage or leakage, takes a special rate with a minimum charge of thirty-five cents, this sample cost me just that amount. I could have sent it much further for the same money. As it was, it had to go to New Orleans for the first transfer, then across Louisiana and Texas. After this long trip it reached its destination in perfect condition.

My next shipment consisted of four cartons placed in a box into which they fitted, with hay in the bottom and around the sides. The top was open except that wire was zigzagged across to keep the carton in, and half a barrel-hoop was used for a handle, also as a guard to keep the box from getting tilted over on one side or getting turned upside down. This and subsequent shipments made in the same manner also went through without a single comb cracked or bleeding. My recollection is that the four cartons complete weighed forty pounds, and the special rate was \$2.10 per hundred, or 84 cts. for each shipment. Articles that take a special rate by express take pound

rates—that is, you multiply the pounds by the rate per hundred; and in shipping any thing by express one should always find out whether the article to be shipped is entitled to that rate.

When the parcel post is prepared to give the matter entrusted to it the same care that the express companies do (and that time will not be any longer than it takes the Department to work all the details out) I believe that the method I have here outlined will be the best for small shipments of comb honey. One can then have any number of customers in all parts of the country, and can send five, ten, or more pounds of honey with perfect safety at a saving to both producer and consumer. By then, too, Brother Root will be making or supplying baskets and cartons to the trade, so that it will not be necessary to call upon the saloon business for help.

Several times while in the express business I accepted shipments of comb honey in strong boxes and in the ordinary glass-front shipping cases. One such, going only ten miles, was so injured that the contents had to be sold as bulk comb; and another going one hundred miles had leaked so that it could hardly be handled. I never knew of any that entirely escaped.

The following are the essential points in handling comb honey: First, the comb should at all times be top side up, just as it comes from the hive; second, the container should be such that all vibration is taken up; and, lastly, the package should be of a kind that all parties who handle it would know at a glance that it required the greatest care. In case the shipment is to be made by freight, the package should be strong and well braced; if by express, in as light and fragile but as well packed a container as possible; if by mail—wait a while and let us have a little experience first. Ultimately, however, I believe we can ship by mail the same as we do by express now.

STEAM FROM A TEA-KETTLE FOR THE UNCAPPING-KNIFE

BY J. L. BYER

For the past few seasons we have used the steam-heated uncapping-knife, and like it very much, particularly if the honey is very thick and the weather none too warm. The picture shows my son in position for operating. But with snow on the ground and a heavy cap on the operator, it does not look very "seasonable." However, it shows very plainly the outfit we have worked with which has given good satisfaction. The kettle shown is only a small one, holding

A boiler for the steam-knife, made from a tea-kettle.

about a quart of water. The spout was removed, and one from a common machinist's oil-can was soldered on instead. It was placed in a more upright position as will be seen; and as it tapers toward the end, the rubber tube fits on closely. To keep steam from leaking around the lid of the kettle, two or three thicknesses of cheesecloth were put over the opening and the cover then pressed in. Small as this kettle is, once filling with water will last half a day. A single-burner oil-stove is used, and this has given sufficient heat, with the exception of a couple of very cool days last

350 lbs. of wax from the cappings from 35,000 lbs. of honey—one pound of capping wax to 100 of honey extracted.

Sawing "bee" in Ontario.

fall, when extracting buckwheat honey. But as a two-burner stove of this pattern costs less than a dollar, one can easily use the larger size if desired. The cappings are allowed to drop into the regular style of uncapping-can, and after draining well are left to be attended to in winter season, when we are not so busy. They are then either washed and the sweet water used to make vinegar, or else the cappings are run through the capping-melter; and the honey is then sold with the buckwheat crop the following season.

The picture shows 350 lbs. of wax that we have just run through the Hatch-Gemmill press, being the product from the cappings from 35,000 lbs. of honey. Although the cappings were pretty well drained last summer, when running them through the melter this winter we got about 600 lbs. of honey. Really it was a surprise to us as to where it all came from. It has a cooked taste; but that from the clover is not a bad honey after all. It will be used for honey vinegar in the spring, while the darker grade will go, as we have already stated, with the buckwheat honey next season.

Some may wonder why we run the cappings through the press, and I might say that there are always some bits of comb, etc., that make it necessary to strain the wax any way, and, all things considered, we think we can make better time and a better job by putting it through the press and finishing at one operation.

The sawing "bee" shown in the picture

is not directly related to *Apis mellifica*, of course, and yet indirectly the operations depicted have had a great influence on bee-keeping. As we drive through the country, the denuded landscape makes us painfully alive to the fact that soon there will be no more of these sawing-bees, as basswoods, maples, and other trees are fast disappearing. Not so long ago it was the custom for nearly all the farmers to have a year's supply of fuel cut at these gatherings, and often in the evening a social time would be spent by the happy young folk. Now the farmers who burn wood in our section are the exception, as coal and kerosene have replaced the wood. More than that, the coal now bids fair to be soon superseded, as everywhere you hear the farmers and others speaking glibly of "hydro-electric" as the coming source of fuel, light, and power in the near future. Surely we are living in a changing age; and the beekeeper, no less than the farmer and artisan, has to adapt himself to the changed conditions and govern his operations accordingly. No, the young women do not cut the wood here in Ontario, as the picture might lead one to believe, but who will look into the smiling, healthy faces and dispute the fact that they would be able to do so, if circumstances should ever put them to the test?

Mount Joy, Ontario.

[Rendering well-drained cappings in a melter generally results in scorching the honey somewhat, owing to the fact that the

amount of honey in proportion to the wax is small. We are surprised to note that, out of the total weight of 950 pounds of drained cappings, nearly two-thirds of the weight was honey.—Ed.]

SOME CAUTION IN THE TREATMENT OF DISEASE

BY J. M. BUCHANAN

I must take issue with E. D. Townsend, pages 760, 813, Dec. 1, 15, as to the use of combs which have contained American foul brood. While it may be possible that all the diseased matter may be cut out, still it is impossible to know when this is done; and it seems to me that it is running a great and unnecessary risk to use such combs. The germs of the disease are carried in the honey to all parts of the hive; and who can say, without a careful microscopic examination of every cell, where these germs may be? It is not alone in the cells that have contained diseased brood, but in many cases it may be above the excluder, remote from the brood-nest.

While brother Townsend may be able to control the disease in this manner—that is, by cutting out the diseased portion and using the rest of the comb—still the rank and file of careless beekeepers will undoubtedly make a mess of it, if such practice is sanctioned by the bee journals. Like J. E. Crane, in my work as inspector I have found all kinds and conditions of beekeepers, and by far the majority are too ignorant or too careless to treat the disease suc-

cessfully by any of the modified methods. The best and safest way, I have found, is to recommend shaking into an empty hive and carefully burning or burying all of the frames, combs, brood, and honey from the old hive. The hive may be saved if properly scorched out.

USING COMBS FROM A SUPER OVER A DISEASED COLONY.

Last year the editor stated that the combs from a super over a diseased colony might be used with safety. To give the matter a test I took three combs from over a diseased colony. They were fresh combs and above an excluder, and I gave them to a clean colony late in the fall. As soon as brood was started in these combs in the spring, the disease appeared, showing that such combs are not always safe.

DON'T FOOL WITH AMERICAN FOUL BROOD.

While a careful manipulator may experiment with European foul brood in many ways with impunity, it does not pay to "fool" with American foul brood in an apiary where there are healthy colonies. There is much danger of robber bees spreading the disease; also danger of the operator carrying the infected honey on his hands or clothes to other colonies.

I have found carbolic cloths a very valuable aid in the inspection and treatment of diseased hives, as they are the best preventive of robbing that I know of. Old burlap bags are cut up and sprinkled with crude carbolic acid, and spread over the hive or over the combs that are removed. By the way, these same cloths when dry make the most satisfactory smoker fuel.

It seems too bad to destroy nice fresh combs that, we fondly hope, might be clean; but it is safest in the long run, where one is not prepared to render them entirely out of the reach of bees; and few beekeepers are thus prepared. I have burned hundreds of nice straight all-work-er combs, and buried the ashes; and, while it hurts my feelings to do so, still it is "good riddance to bad rubbish."

DO NOT USE MAILING-CAGES FOR INTRODUCING.

Another careless practice that should be avoided is the in-

Piece of comb built in six days after a queen was introduced.—
From E. G. Ward.

How clover is getting a spread in the wild lands of the Northwest.

roduction of queens in mailing-cages, when it is impossible to say that the candy in the cage is not infected. I suppose nearly all queen-breeders are reasonably careful in using clean honey to make candy; but there is always a risk to run; and it is easy to be on the safe side by using a clean cage, if one must use this antiquated method of introduction, being careful to burn the mailing-cage, together with the escort of bees. By using the direct method of introduction the danger of infection is avoided, and at the same time the safe acceptance of the

new queen is insured. This method has been given several times in GLEANINGS, and is in use by hundreds of up-to-date beekeepers, so it is useless to describe it here.

In the treatment of brood disease the safest way is none too safe; and just as we should avoid the appearance of evil, we should take no chances with American foul brood, knowing that the vast majority of beekeepers are none too able to cope with the disease at the best.

Franklin, Tenn.

Sheep clearing brush lands for clover crop.

FORMER FOREST LANDS BEING CONVERTED INTO CLOVER-FIELDS

BY J. L. GRAFF

Sheep and clover are working a dual part in the vast tracts of cut-over and burn-over lands in Minnesota and other northwestern territory in which the last of the lumber is fast disappearing. The promise of increased fields of clover bloom has much in store for the beekeepers of that region.

Sheep are being brought from Montana and other far-western ranges to feed on wild land for the purpose of clearing out the brush preparatory to the sowing of clover. It is claimed that twenty ewes will clean up five acres in as many months, and leave the ground so clean that, when the frost is coming out of the ground the following spring, seed will catch without any other soil preparation, and a good stand of clover will be secured in this way. At least two crops are cut in one season. By fencing small tracts and changing the sheep from one tract to another, the patches are well cleaned and the sheep take on a sufficient quantity of mutton to sell for much more than they cost when they were turned into the fields.

One of the illustrations shows the character of the land being cleaned up. No attempt is made to take out the stumps; the seed is sown between them. In the lower right-hand corner is shown for contrast a small section cut from a photograph of one great field of clover in bloom. From this corner picture one may imagine what kind of improvement could be seen if the clover were to spread over the whole tract. In one county alone in Minnesota, efforts are now being made to clean up two million acres.

Chicago, Ill.

ENTRANCE AT TOP OF HIVE AN AID IN SWARM PREVENTION

BY I. W. BECKWITH

I have read several items in the bee journals, in which the writers complain that bees are adverse to going up through the queen-excluders with their loads of honey, and so deposit too great an amount in the brood-chamber, thereby crowding the queen and causing swarming. Some beekeepers call the excluders "honey-excluders," and thereby denounce their use.

I thought that, as the bees object to carrying their honey up through the excluders, perhaps they would object to carrying it down through them, and so I might take advantage of that propensity by reversing

the process. So when I set my bees out in the spring I closed the fly holes at the bottom of the hives and moved the lids back so as to allow entrance at the top. It is best to do this, on setting them out, before they have become accustomed to going in at the bottom. If they become accustomed to using the bottom exit it will be necessary to close it tight so as entirely to exclude the light; and even then the bees inside will crowd that part of the hive, and those outside will try to go in there for a month after the change has been made.

As soon as a super is needed, take the escape out of the escape-board and tack a piece of queen-excluder over the hole; put it on the hive, and a super having an entrance at the front end. I prefer to have this piece of queen-excluder near the front end of the board so that the bees may find it more readily. It may be well to put the escape-board in place at first, leaving off the zinc until the super is needed.

The result of my experiment was not only that the honey was stored above (only enough carried below to feed the young, the queen having unlimited room). The bees raised so much brood that they were soon very strong in numbers; and before the season was over they occupied two extracting supers and then one half of the bees clustered on the outside of the hives, there not being room inside, and not one of the 22 colonies so treated offered to swarm.

I wanted to divide some of them, and so put brood above for them to raise queens *a la* Doolittle; but they would start no queens; and when I gave them cells nearly ready to hatch they either tore them down or the few that they allowed to hatch soon disappeared, so I conclude that I have unwittingly solved the swarming problem.

This was three years ago last summer. I then quit the bee business and left Wyoming for this State.

I used extracting-supers, having some old brood-combs containing pollen. I am not sure but the bees may have stored some pollen above; but if so it was only near the entrance to the brood-chamber.

In order to give my bees more ventilation than this arrangement would allow I tacked wire cloth over the lower entrance.

Rodeo, N. M.

[A number of beekeepers at one time or another have used upper entrances—most of them, however, using them in connection with a lower entrance also. The objection to having but one entrance, and that at the top, is that in localities where the nights are cool there is danger of having the bees desert the supers, and also that the brood

may become easily chilled. Then at certain times of the year it seems to be almost imperative that bees have an entrance at the bottom of the hive to facilitate carrying out dead bees, debris, etc.

The experiment described by our correspondent is an interesting one, however, and in warm climates would probably be worth trying. There is no question but that, in very hot weather, an upper entrance in addition to a lower one facilitates the storing of honey and saves time and bee energy. There is also somewhat less danger of swarming on account of the added amount of ventilation afforded.—Ed.]

DOES THE ADDING OF EGGS AND LARVÆ TO A COLONY WITH A VIRGIN SOMETIMES CAUSE HER DISAPPEARANCE?

BY JOHN H. JOHNSON

Dr. Miller, p. 718, Nov. 15, asks that some one settle this question. The doctor had evidently thought the question settled long ago. And now comes one, Arthur C. Miller, unsettling it, and making the doctor trouble. At Medina, Ohio, it seems the boys thought so too, as both Mr. E. R. Root and Mr. Mell Pritchard have endorsed the giving of eggs and larvæ. By the doctor's confession, that policy did poorly enough at Marengo. When it comes to prescribing it for the whole country (I mean no discourtesy), the doctor might better say, "I don't know."

If by giving eggs and young larvæ I lost 8 out of 17 virgins I too, like Dr. Miller, would want the question resettled. I am thoroughly persuaded that the season and the locality have much to do with the disappearance of virgin queens. The treatment that may do fairly well at Marengo and Medina may not do at all at Bangor, Pa., nor at Providence, R. I.

I kept bees for about 43 years, and raised my own queens and some to sell, for about 35 years. Beekeepers then, in this section, reared queens in nuclei and practiced artificial swarming to some extent. We strengthened both kinds, even while they had virgins, by giving eggs and larvæ. The loss of young queens was heavy, especially some seasons.

I observed that the colonies that swarm naturally rarely lose their virgins. About that time I also read that the giving of eggs and larvæ endangers the life of the virgin queen. That led me to decide that nature's way of having the stands eggless and larvæless at the time of the young queen's mating is the proper way. I now closely watched to see what treatment the bees gave

the virgins upon their return from successfully meeting the drone. I saw that the eggless and larvæless stands very rarely balled their young queens. But in times of dearth of honey, those stands having eggs and larvæ were veritable fiends at balling their newly mated queens. I found a few that the bees had smothered by the next morning. The dead queens were dry and glossy. Some of these balled queens were released by the bees, and became laying queens, with now and then a leg disabled or wings ragged. Most of those balled had that black glossy appearance as though they were varnished. I should like to hear from other beekeepers regarding their observations.

The past season I permitted 14 colonies to swarm naturally. There was a loss of one virgin among the 14. I reared in nuclei, I think, 26 queens with a loss of two virgins among the lot.

I should like to request that Dr. Miller try the eggless and larvæless method another season, with nuclei that have virgin queens, as compared with the egg-and-larvæ method.

Bangor, Pa.

HIVING A CLUSTER OF BEES FROM A RAIL FENCE

BY MRS. FRANK M'GLADE

After reading Mr. J. L. Byer's article, page 301, May 1, about hiving a swarm of bees on a rail fence, I thought another experience along that line might be interesting to the readers of GLEANINGS.

Early one morning in June a swarm of bees came out and settled on a barbed-wire fence near the beeyard. Soon after, another came and settled near the first. While I was busy hiving them, a third issued and settled above the two hives with which I was working. The first swarm went in all right; but when the third had settled so near the other hives, the second was not managed so easily. I finally succeeded in hiving them, however, and went to the house. On going out in the evening to remove them to a different location I found both hives empty with the exception of a few stray bees. Any beekeeper can imagine just how I felt. We looked everywhere for them, but in vain.

Two days later, however, just after dinner, my little son started down across the back lot in search of wild strawberries. As he was crawling through a hole in the old rail fence, he almost touched with his head a cluster of bees on the rails among the briars and tall weeds. He called to me to come quickly, saying that he had found the

bees. There must have been a bushel of them. I determined then and there to have them yet at any cost, even if I could find no one to help me. I realized that it would be useless to try to shake them off, so I pushed my way as close to them as I could and set a box near them. I stretched a sheet over the box down under the bees and started the smoker. I worked with those bees for three hours, but they seemed determined to cling to the old rail fence. I kept on using smoke, driving them toward the hives, which were full of old comb, as the former occupants had starved.

When one hive was so full that there was not room for any more bees I moved it and put another in its place. I again smoked them toward the hive. When a woman will, she will; and after three hours of work the bees were safely in the hives. I found that they had already started a comb on the fence. I kept close watch over them until evening, when I moved them to their future stands. I wore my veil, but my hands and arms were bare, and yet I had not received a single sting. The next day I removed a frame and placed a frame of brood in each hive. I found later that one colony had a queen which soon began laying. That colony produced over sixty pounds of honey, fall flow. The other soon raised a fine large queen, and they are the strongest colonies I have this spring.

I had quite an interesting chase of hide and seek with them at one time. After going through a hive three times I found the queen, so large that I wondered how I ever missed her.

Another time a bumblebee flew into the hive. How the bees did pounce upon it! They finally drove it out.

While I find the care of bees rather tiresome work, yet it is both interesting and profitable. It is a kind of work, too, which any woman can do if she will.

Hebron, Ohio.

SOME OBSERVATIONS ON THE MANNER IN WHICH BEES USE THEIR STINGS

Is it Natural for Bees to Lose Their Stings After Using Them?

BY WILLIAM BARNES

In December 1st issue, page 778, I noticed observations in regard to bees stinging each other. My own experience has been somewhat different, for I have noticed on two different occasions stings left in workers after being stung. One was during a case of robbing, and the other where a small swarm had entered another hive of

bees. There were dozens of bees with the stings left in their thorax and sides. I saw one bee with as many as three stings lodged in it. Time after time have I watched the effects of a fight since, but have failed to find stings left in the dead bees.

The other day (after reading the articles) a very small queenless swarm came and settled on a hive-cover; and as I had a very weak queenless colony I thought I would run the swarm into that hive so as to make them strong enough to be worth a queen if they would unite; but they didn't. They declared war, and fought it out to the bitter end. I watched the results, and examined the dead bees afterward, but failed to find even one bee with a sting sticking to it. I myself have never seen either a queen or drone with a sting lodged in it, but have often seen bees bluffing at stinging drones, but never really saw them do it.

I agree with the editor that it is not necessary for bees to lose their stings when using them against each other. I would also go further and say that I don't think it is in accordance with nature for bees to lose their stings when stinging any thing, as the loss of the sting is more often brought about by some disturbing agency other than the natural instincts of the bees. I should like to have some of you old hardened beekeepers take the time and trouble (yes, you will have some trouble to keep from smashing your little pets), when working among four bees, to give them a good test in regard to stinging.

If you see a bee (or feel it) alight on you and sting, don't move, but just grip what you have hold of and watch, wait, and suffer. You will see some funny antics (on the part of the bee) in her desire to free herself, which she will accomplish about eight times out of ten if you don't molest it in any way, something after the way in which they free themselves after stinging each other, only it will take much longer on account of having much tougher material to work on. Of course I am speaking of bees in their normal state, not those that have been stirred up to the pitch when they are just longing to throw away their lives on account of an unnatural state of things being brought about, such as dropping a frame of bees, overturning their homes, or stirring them up with your foot, etc.

In regard to bees stinging animals, the latter, on being stung, will invariably start to play up, thereby angering the bees into doing their best (or worst) by leaving their stings behind, and then trying to do the trick over again.

One remarkable thing in letting a bee extricate itself from your arm or whatever

part it has got hold of, is that the pain is most severe at first, and keeps on diminishing until it has freed itself, when a slight rub will let you breathe normal again, and you will hardly know that you have been stung.

Strand, N. S. Wales, Australia.

DO BEES LOSE THEIR STINGS WHEN STINGING OTHER BEES?

My experience leads me to say they do not as a rule. I have watched them closely, and apparently they insert only the extreme tips of the sting. Now and again one appears to get the sting too far in; and when they find themselves caught they appear to be panic-stricken, and make frantic efforts to withdraw the sting, with the result that they tear it out of their own bodies. If a bee stings a man, and is let alone, it will sometimes turn round and round; and apparently, by making the hole large enough, will be able in a short time to withdraw the sting; but I never saw them do this when attached to another bee.

MAJOR SHALLARD.

South Woodburn, N. S. Wales, Australia.

BEES DO NOT ALWAYS LOSE THEIR STINGS.

I have just read what Mr. Waugh says, p. 778, Dec. 1. When I kept pure black bees in box hives they always had a lot of drones. Many times I have seen the ground covered with dead drones, and they did not have any stings in them. Since I have been keeping the yellow bees I never see any dead drones. One day last summer I was extracting honey when a large bumblebee got inside of the screen cloth over the window. There were also a lot of bees there. When the bumblebee would get close to one it would try to catch it, but it would always get away. I thought I would have a little fun, so I put the bumblebee in a bunch of bees. They soon covered it. They had a tussle for a few seconds. It soon got loose from all but one, which held on for some time. In a few seconds after the last bee released it was dead, and not a sting in it.

I wonder how many of the GLEANINGS readers can say that there have been bees at their homes since 1838. The year that my mother was born in (1838), grandfather bought a colony in a box hive. He would always choose a few of the best colonies to keep, and kill the rest with sulphur. He followed this plan till his death in 1879. Mother kept up his plan till I began to care for the bees about 1885. I soon after adopted the plan of robbing them, as it was called. I kept this up until I began to use the frame hive in 1900, and it was the same

stock too. Mother never knew what it was to be on a place without bees, as they were brought here the year she was born. She lived in the house that she was born in till her death this year. Since I have been using the frame hive I have changed from blacks to Italians. I have read what the several writers have said about the light and dark colored bees. My experience is that the goldens are not worth much more than house flies; and the Holy Lands are worse than the goldens.

Havana, Ala.

J. S. PATTON.

On page 116, Feb. 15, Mr. Elias Fox says, "I have seen a good many queens and thousands of workers killed by being stung. I have yet to see the first bee with a sting lodged in it." Further on he states that he never was able to make a queen sting him, and asks if any one was ever stung by a queen. Now, both those things occurred at the same hive and on the same day in my presence, proving that, out of an infinite number of possibilities, great improbabilities and coincidences may occur.

I had been from home two days attending outyards, leaving an eleven-year-old daughter in charge to cage the clipped queen and let her go again as soon as swarm returned. She reported, among others, that "39" had swarmed both days. This morning I was at home and at work when "39" came out again. As we had been having wet weather for some days prior to the last two, I hardly expected to find the queen out again, for, in addition to their reluctance to come out when they find they can not fly, there was the possibility of her being killed by a virgin; but, contrary to my expectations, she was again found climbing the weeds and attempting to fly. I duly caged her and placed her on the alighting-board. After the return of the swarm I went over to liberate the queen, and noticed that there were no bees on the cage as usual—in fact, only about four or five bees were visible at the entrance. I removed the plug and laid the cage a few inches from these bees. Immediately after she left the cage one sprang at her and buried its sting in her thorax, and she was dead in 15 or 20 seconds—long before the contractions of the sting had ceased.

Looking through the hive I found several ripe cells, none empty, though the mandibles of one young queen were plainly visible cutting its way out. The bees were dark hybrids, and very cross, so I decided to re-queen from a nucleus, cutting the cells out. My little girl let the young queen run into her hand, as she had often done before. In

answer to her request to let this young queen live I explained my reasons for not wishing to perpetuate this strain, when she suddenly opened her hand and threw the queen in the grass, saying it had stung her, and pointed to the place where the sting had entered. I sympathized with her, telling her that she had had a unique experience, as queens were not in the habit of stinging any thing but a rival. She remarked that it did not hurt as much as a worker did.

B. B. BREWSTER.

Greenridge Marr, Canada.

In reading the Feb. 15th GLEANINGS to-night, page 116, I saw that Elias Fox wants to know if any one was ever stung by a queen bee. I have been. It was at the beginning of my apicultural experience. I had two (virgins) I think, in my left hand. There was war at once. Of course one went for the other. The other avoided the thrust somehow, and I received the sting just below the second joint on the second finger. It hurt severely. The queen that stung the other flew away; but I kept the other one, and I think she mated.

JOHN H. RISING.

Lestershire, N. Y., March 23.

ANOTHER STUNG BY A QUEEN.

Not wishing any more increase when a swarm issued, I hunted out the queen and intended to kill her. I caught one and pinched her head, and she stung me on the finger. This is the first and only time I was ever stung by a queen. She was a full-sized normal queen that had come forth with the swarm.

Kokomo, Ind.

ELI ROBERTSON.

GREASEWOOD OR CHICO

BY J. A. GREEN

Wesley Foster is evidently not well informed as to our desert flora, else I have been laboring under a misapprehension for many years. The plant which he illustrates and describes as greasewood on page 50 of GLEANINGS for Jan. 15 is not what is called greasewood here, but chico or "rabbit brush." Greasewood is one of the most common plants of the arid plains of the West, being second, I believe, only to sage brush. Here it is the principal one of the woody shrubs of the desert, giving place a few miles further west to sage brush. It is a straggling, seraggly bush, growing sometimes five or six feet high, though usually not over three. The wood is very hard; and, though it has no real thorns, the tips of the twigs are so sharp that the effect is about the same as though it were thorny.

The leaves are narrow and very fleshy. When young, stock browse freely on the green tips; and, though it has not a very high reputation as pasturage, it is, according to analysis, almost as nutritious as alfalfa. The blossoms, which come in early summer, are very inconspicuous, small, and yellowish-brown. The bees work on them very freely for a few days, getting considerable pollen and some honey, which, I believe, is very dark in color, though of good flavor.

Chico blooms late in the fall, resembling goldenrod in this respect as well as in appearance. The bees get quite a little honey from it, deep yellow in color, rather thin and poor in quality. It granulates very quickly, even in the comb; and the section of alfalfa or sweet-clover honey that is finished up on chico is not very much improved thereby, as the chico honey around the lower edges granulates long before the rest of the honey. The worst feature about it, though, for the comb-honey producer, is the intense yellow color of the pollen, which stains the surface of the combs over which the bees travel, besides giving them its smell, and to some extent its flavor. As this smell and flavor are very much like that of the common garden marigold, it does not improve the quality of the section honey which remains on the hive through its flow. On this account, many beekeepers remove the supers from the hive as soon as the chico begins to bloom. After the plant is through blooming, the appearance is very much the same, except that the yellow of the blossoms is changed to white. This white tufted appearance, somewhat like a rabbit's tail, probably accounts for its other common name of "rabbit brush."

Another slight error in this article, not of much importance to a beekeeper, perhaps, though it might be to a homeseeker, is the impression which it gives that peaches are raised by the hundreds of carloads near Fruita. Peaches are not commercially grown to any extent near Fruita, though apples are one of the main crops. The peach district begins fifteen or twenty miles east of Fruita; and it is here that hundreds of tons of the finest peaches grown in the world rotted on the ground last autumn, because, although we have one of the best organized fruit-shipping associations in the world, our system of distribution is so poor that it would not pay to ship these peaches, though thousands of people could not get any peaches to eat because the price was too high. Some time, let us hope, the producer and the consumer may be brought nearer together, to the advantage of both.

Heads of Grain from Different Fields

The Starvation Cure for Foul Brood; the Importance of Treating Promptly

I have a copy of your A B C of Bee Culture for 1905, and I wish to ask you about an article on page 170, second column, about half way down. You say, "When the bees begin to fall from the comb as if from starvation, they were fed." Does this mean that they were closed up in the hive after giving them sheets of foundation for foul-brood treatment?

Would you advise treating for that now, or wait until after the honey-flow? and about what date then would you advise?

I also intend to Italianize. Would you advise me to do this after the honey-flow too? I have five hives of hybrids.

Ashland, Ky., April 21. JOHN M. O'DW ER.

[Referring to the method of curing foul brood as given in the edition of the A B C of Bee Culture which you have, we would say that our idea was to put the bees in a wire-cloth cage or in a hive having a screen top so that the bees can get plenty of air while they are kept away from the combs, and during the period where they are being starved, until they just begin to drop down. If they were shut up in an ordinary hive tight, without any special ventilation other than that given at the entrance, they might suffocate; but nowadays we have a little more modern method of cure by which we do not have to starve the bees at all. We let them loose on frames of foundation. We are sending you under separate cover a copy of our booklet, "Diseases of Bees," and would refer you to the special treatment given for foul brood.

Always in bee diseases of any sort, especially American or European, we would advise immediate treatment. To defer the matter until after the honey-flow would only subject your other colonies to the danger of infection; and it is better to treat when the bees are not inclined to rob than at any other time. If the fruit-bloom is all over with you it might be advisable for you to shake your bees on to frames of foundation, as given in our booklet, along about sundown, or possibly a little later—just late enough so that robber bees would not cause any trouble. The combs themselves then should be thoroughly burned and the ashes buried.

The matter of Italianizing the bees can, perhaps, be deferred to advantage until after the honey-flow.

We should be very glad to have you come and see us at any time. Our apiaries are open to inspection, and beginners are always welcome, or any one else. When you come, make yourself known and we will see that a man takes you over the plant and gives you opportunity to see actual work among the bees. If you can stay long enough we will give you a chance to go out to the outyards where the men are at work.—ED.]

Another Plan for Running for Increase and Extracted Honey Both

I have fifteen hives of bees which I wish to increase to thirty. Twenty I intend to run for extracted honey, and ten for comb. Will the following plan work? When the colonies get quite strong I will give each a second brood-chamber filled with comb, or full sheets of foundation. Every few days I will reverse the brood-chambers, top for bottom. When the honey-flow comes on I will take one brood-chamber filled with the heaviest frames of brood, the queen, and some young bees, and set them on a new stand, leaving the hive on the old stand to raise a new queen. I will then give each a super. I will make the change in the middle of the day when most bees are flying. I have 200 lbs. of sugar on hand. I will feed until I add the second brood-chamber, which will be when the fruit-trees start to

bloom, or perhaps before. Would it be advisable to raise some young queens and have them all ready to introduce to the hives I leave on the old stands?

Troy, N. Y., April 14.

W. H. ROBERTS.

[Giving a colony an extra brood-chamber filled with empty combs or frames of foundation is correct enough in principle; but there will be no particular advantage in reversing the position of the brood chambers unless you use perforated zinc and put the queen below the zinc with the empty combs or frames of foundation. Without the queen-excluder or perforated zinc, the queen in all probability would stay with her brood-combs whether she was in the bottom story or in the top story. She would gradually, however, work into the other story that had the empty combs or frames of foundation, no matter whether it were below or whether it were on top. A much better plan than reversing the brood-combs, and which would accomplish the object which you are seeking, would be to scatter the brood—that is, after settled warm weather has come on. At the time of giving the extra hive-body on top, remove some of the brood-combs from the lower hive and put them in the upper hive. Fill the spaces in both hives with frames of foundation or combs, placing the empties in alternation with the frames of brood. But be careful not to overdo this. It would be very much better, at the start, to bring up one or two frames of brood in the upper story along with the empty combs and frames of foundation. Place the two frames of brood together. At the beginning of things it is wise not to scatter the brood too much; but when the swarming season begins and the bees feel inclined to swarm and hang out, then we advise alternating a frame of brood with an empty frame of comb or frame of foundation. As a general thing this will entirely check swarming for the time being.

Your scheme of taking away the brood-chamber containing the heaviest frames of brood is correct enough, with this exception: It would be better to use only frames of sealed brood. If you effect this removal at the time when the bees are flying the heaviest, and leave plenty of young bees with the hive removed, there will not be much danger of chilling the brood, providing the weather is warm enough at the time. Taking every thing into consideration we think you will find the Alexander method of making increase, recently given in GLEANINGS, will suit you better. See page 314 of GLEANINGS for May 1.

Yes, you could raise young queens and have them all ready to introduce at the time of making the division; but before you raise any queens you better read the article on "Queen-rearing" in our A B C and X Y Z of Bee Culture, or in our booklet, "Modern Queen-rearing."—ED.]

No Pollen-producing Plants in Bloom, a Result of the Frost

In returning to my apiary from the north last week I found every thing at a standstill; but little brood-rearing was going on, and the bees were weaker in numbers than ever before in my experience at this time of the year. I soon saw, from inspection, that they were entirely destitute of pollen, and not a speck was coming in. The bees were heavy from well-filled combs of honey which was fed to them last fall. I never had such an experience before, as pollen is always abundant here, even when honey is absent. I never had to feed flour before in my experience of more than thirty years. The bees went at the rye flour like hogs to swill. They were more ravenous over it than when robbing. My one hundred colonies took in four quarts each day, for a week, and stored but little of it, and the weather, too, was very cold for this season of the year.

I now see that the pollen flowers are absent, and

the pollen trees and shrubs are killed from the late heavy frosts which visited us in all parts of California. The willows and cottonwoods will, no doubt, bloom later, as only the limbs are dead. Other shrubs seem to be completely killed.

Lonoak, Cal.

C. K. ERCANBRACK.

Equipment for Production of Comb Honey

Dr. C. C. Miller:—After nine years' experience with extracted honey I think I'd like to go back to the production of comb honey. Now, if you were to start over with a new outfit, what super and style of section would you use? How would you arrange the inside of the super? What kind of furniture? Would you have two extracting combs, one on each outside? I had thought I'd like section-holders with top-bars, then I would put the sections into the section-holders and put the foundation in afterward (full sheets). I have done so on a small scale, and in this way no foundation is ever broken loose. Does Fifty Years among the Bees give the whys and wherefores?

Mr. Townsend speaks as though he likes the T supers with two extracting combs, one on each outside. He too figures the cost of production and tries to cut it down.

Battle Creek, Mich., April 27. WM. C. BROWN.

[Dr. Miller, to whom the above questions were addressed, replies:]

I would use the T super, and it would likely be with a ten-frame hive. Besides the T-tins, the only furniture would be plain wooden separators and little sticks to crowd between the tops of the sections to keep sections square and prevent bee-glue. These sticks are about $\frac{1}{4}$ -inch by 3-32. I think I would at least do some experimenting with an extracting-comb at each side of the super. The sections would be $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ beeway, filled with full sheets of foundation, top and bottom starters.

You will find twenty pages or so devoted to the subject in "Fifty Years among the Bees."

Marengo, Ill.

C. C. MILLER.

Bee Paralysis or Poison?

We are experiencing a trouble here with our bees that we have never had before in this section that I know of, which is this: The bees are dying right along. It seems to be the old bees that are affected, and one would think it was caused by spraying were it not for the fact that there has been no spraying at all in this section. The brood is in fine shape, and the young bees seem to come out all right; yet the colonies do not build up; in fact, many of them are going back rapidly, yet practically all colonies are affected, and all yards that I know of are affected about alike, and I know the conditions over quite a bit of territory. We have never had any disease here at all, to my knowledge, before the present trouble.

Some think it paralysis; but I do not think it is. I have A B C and X Y Z of Bee Culture, and have made a study of bees more or less for the last twelve years, and must say that I am puzzled; but I am inclined to think that it is caused by gathering honeydew from the excessive amount that we have had here all the spring on pine-trees. It has been in such quantities that one could rub his hand on the grass under the trees and get them coated with the substance. We have had much cool weather and especially nights, many days being so cool that the bees would hardly get any flight at all; and if I can see any difference I think we have more dead bees after the coolest weather. The ground in front of the hives is covered with dead bees; and in some instances where there is grass it is even killed by the dead bees. The combs are full (in all colonies that are at all strong) of this honeydew, and the queens are laying finely. It is now 9 A. M., and I have stopped writing long enough to run out and examine

the fronts of the hives, and find fewer dead and dying bees than on last Tuesday morning when it had been cooler than now. For the last day or so, say three days, it has been fairly warm, almost hot. Many of the bees are carried out alive, but sick, and hop around on the ground, sometimes living over night in this sick condition. They look swollen and slick, while the majority are dead when carried out.

Rock Mount, Va., May 2.

B. L. FISHER.

[Notwithstanding what you say to the contrary, we should be very strongly inclined to believe that what is killing your bees is paralysis. Your preliminary description rather points in that direction, and the last sentence of the next to the last paragraph seems to leave no doubt of it in our minds. No form of honeydew, nor any honey, in fact, that we have ever known any thing about, will cause the kind of malady you describe. Your bees might possibly have been poisoned; but we hardly think that is probable in view of the last sentence referred to in the next to the last paragraph, especially where you say "they look swollen and slick." This is a very unmistakable symptom of bee-paralysis, and, taken in connection with all the rest you say, makes it very clear to us that there is nothing else the matter with your bees.]

If you will follow the directions given by Mr. O. O. Poppleton, who has had as large an experience with it as any one, as given under "Bee Paralysis," in the A B C and X Y Z of Bee Culture, you will be doing about all that you can do for them, because we do not know of any easy and simple cure. One thing we would suggest, we would isolate all the sick colonies and locate them in a yard by themselves. We would change the queen in all the colonies, and then practice the treatment recommended by Mr. Poppleton.—Ed.]

Why do Swarms Cluster Before Leaving?

On p. 502, Aug. 15, 1912, you give my theory as to the possible reason "why swarms cluster." I wish you would again put it before your readers, asking those who might desire to test it to report results.

We have by the "wing-clipping method" a decided aid in handling primary swarms; but it is the after-swarms that not only can and do make us climb, but that sometimes beat us completely; and it wouldn't hurt a bit if one more slat could be added to the knowledge our older veterans have given us on handling this problem.

One day after the issuing of a swarm from a hive wherein all eggs had been hatched and all brood beyond the possibility of making into queens, I destroyed all the queen-cells and allowed the swarm with a queen to hang as long as the bees would. After remaining clustered for an hour and a quarter they quickly broke; and before I got to the second fence they were ahead of me, though I was doing my best to keep up. At a distance of about 50 rods they had abruptly held up, and I was under them again; but instead of being enmassed as they had been, they were scattered; and while I stood out in front of their line of advance for a time, on getting back to the apiary I found the swarm nicely hived at the stand from which it had come.

Sterling, Ill., May 6.

A. B. ANTHONY.

Bees that Would Not go Out of the Pound Packages

In a shipment of some half-pound lots of bees I received from Alabama there was one cage that had been placed over the brood-frames in a super with one end removed so they could escape to the brood-frames. All had escaped from cages in 24 hours; but in this one they would move back and forth to brood-frames for several days. So, upon examination I had discovered they had started to build comb in the little cage in which they came. I also may add

that the queens came introduced, and that this one had started to lay eggs in cells of this comb. The question is, Where did they get the comb? for they could not get out of the hive in all this time, but had brood-frames with comb and honey in the hive. I have never heard nor known that bees could work over old wax, so should be pleased to have this point made clear.

Downer's Grove, Ill., May 6.

J. MEY.

[Bees can build comb while in confinement, for, in fact, they make their wax out of honey. As they were supposed to be supplied with it in your case they could easily build comb; but it is a very unusual procedure. It is not at all surprising that the bees refused to go down on the brood-combs, because, if there was a little bit of comb in the cage that contained a few eggs, the queen and the bees, you will find, would stay where that piece was. They would gradually, however, work down in the hive, because the capacity of the cage would become too limited in a short time.—ED.]

Cottonseed Meal Eagerly Taken by Bees

On age 272, April 15, Mr. Kos Hurst suggests that Mrs. H. Millard, Feb. 15, page 131, use cottonseed meal as a substitute for pollen instead of albuminized sugar or rye meal. Mr. Hurst says that he has never read where cottonseed meal was fed to bees as a substitute for pollen. Bees will carry in cottonseed meal if they can get it early in the spring before there are any flowers or enough flowers to produce the amount of pollen necessary. I have seen bees working so thick in hoppers that contained dry mash for chickens that the chickens refused to eat except early in the morning and late in the afternoon when the bees were not flying. The mash contained a good deal of cottonseed meal, and the bees worked until they had gotten nearly all of the meal out of the mash.

The best way to feed the bees the cottonseed meal is to mix it with wheat bran, half and half. Some of the bees are sure to be drowned if the meal is fed to them just as it is. After the meal and bran are mixed, pour it into a flat box and mound it up. The mash should be stirred and mounded up every day, as the bees work it down level when they get out the meal.

If the weather is favorable, the bees will soon carry in enough to fill the brood-chamber. A little honey smeared around the sides of the vessel that contains the mash will soon attract the bees. Brood-rearing seems to be carried on as easily with cottonseed meal as with pollen gathered from flowers. I am sure that cottonseed meal can be used to great advantage in localities where pollen is scarce in the early spring.

Here at Beeville cottonseed meal costs \$1.50 per 100-pound sacks. A hundred pounds of meal added to bran as needed should supply at least 200 colonies of bees with pollen for at least one month.

Beeville, Texas, May 12.

C. E. ENGLE.

What to do with Sections Containing Pollen when Grading

How many cells of pollen can pass in fancy sections? How many in No. 1? I use excluders, and yet I have lots of sections with pollen. I use the Danzenbaker system of comb-honey production. Heretofore I have sold such honey to farmers at 8 cents for fancy, but it does not pay.

New Boston, Mo.

F. H. THIELE.

[We submitted this to Mr. F. Rauchfuss, manager of the Colorado Honey-producers' Association, and he replies:]

The question of pollen in sections has never been taken into consideration when framing our rules, because in all of the experience that we have had during the last fifteen years there have been probably

one dozen sections found with a few cells of pollen in. For this reason it is a negligible quantity, and not to be considered; but if it were in a location where it happens often, as it seems to in Mr. Thiele's location, we would consider such as not fit to go into anything but the No. 2 grade, no matter how well they may be finished and filled.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION,
Denver, Colo., May 12.

F. RAUCHFUSS.

Sheep Not Necessary to Make White Clover Yield

I agree with Dr. C. C. Miller that it is not necessary for sheep to pasture in white clover in order that it may be more productive. In fact, cattle are better, as they do not eat the crown out of the plant as sheep will do. Poor farming has hurt the land in this locality so far as producing white clover is concerned. The short rotation, advocated by the experiment station at Wooster, for bringing back fertility to our soil, is detrimental to white clover unless farmers sow it; and that is what they should have been doing for years. A chemical analysis of white clover shows that it is richer in protein than almost any legume which is grown for forage.

Bloomington, Ohio.

W. B. RALSTON.

A Correction

In describing my arrangement to get bees out of the extracting-supers, p. 230, April 1, you used a cut which I think does not make it plain. I make the box 18 or 20 inches high. This box could be tight on the sides and ends, except that the side furthest from the operator should have an opening the full length of the box, and about three inches wide in order to give air or ventilation to the bees after they slide down the chute below.

Lakeville, Ind.

C. A. BUNCH.

Removing the Queen

Can as much comb honey be secured from colonies where the queen is removed as by the shaken-swarm plan?

Honeoye Falls, N. Y., Feb. 24. GILBERT BROS.

[Caging the queen to prevent swarming, when running for the production of comb honey, seems to take the life out of a colony. The bees attempt to rear queen-cells; and if a single cell is missed, a swarm will come out very soon after the virgin hatches. The methods of shaking swarms, we should say, would be much more satisfactory than dequeening; and it would be our opinion that more honey could be secured.—ED.]

The Number of Bees to the Pound

Will you inform me of the number of bees in a quart or a pound? If a pound, what is the space they occupy?

Canton, Mass., April 21.

E. C. BRITTON.

[There are about 3200 bees in a quart and about 4500 bees on the average in a pound. This number, however, will vary according as to whether the bees are filled with nectar or not. A bee can carry half its own weight in honey and possibly a little more at times. If, therefore, the bees are filled with honey a proper reduction should be made from the figures already given.—ED.]

Death of Melvin Isbell

I should like to have a brief notice in GLEANINGS of the death of my husband, Melvin Isbell, which occurred May 3. He was a veteran beekeeper, keeping bees since a man of 20. He also took GLEANINGS, since its first beginning, and had nearly every one in good condition. He was 63. I think he kept the most bees of any one in Chenango County.

Norwich, N. Y.

MRS. MELVIN ISBELL.

Our Homes

A. I. ROOT

A soft answer turneth away wrath; but grievous words stir up anger.—PROV. 15:1.

But I say unto you, that ye resist not evil; but whosoever shall smite thee on the right cheek, turn to him the other also.—MATT. 5:39.

Think not that I am come to send peace on earth: I came not to send peace, but a sword.—MATT. 10:34.

It is now springtime, and everybody is making garden more or less. I do not know but I might say likewise that *almost* everybody is keeping chickens "more or less." Well, the chickens are all right and the gardening is all right. Both are commendable. But they do not work well together. If the mother hen is penned up and the little chicks are allowed to run through the garden, they will, at least for a time, do good and not harm; but if you do not look out, the first you know, even small chicks will get into the seed-beds and not only dig them up but make things look sadly untidy. I have sometimes thought that plants become discouraged and give up, just as human beings do. After a chicken has snipped off the foliage and scratched the dirt off from some of the tiny rootlets, the plant will of a sudden lose its vigor and energy. Well, what I have in mind this morning, while we are getting a gentle May shower, is the matter of having one neighbor have a choice garden and the adjoining neighbor some chickens, and trouble comes. Not all of the chicken folks and garden folks are professing Christians; and some of them that *are* seem to forget their religion when the chickens get across the boundary line and dig up the plants. I believe it is getting to be more and more the fashion to dispense with fences; and I always rejoice to see this. We of the United States, especially the Christian people, have no money to waste on needless fences any more than the great powers of the earth have millions to waste on needless "men-of-war." May God hasten the day when men shall beat their swords into plowshares and their spears into pruning-hooks. Of course the chicken man (or chicken woman) must have fences. But the neat tidy fences made of poultry-netting are not at all offensive nor out of harmony with beautiful surroundings. In towns where neighbors are close by on all sides, I would recommend fowls that do not fly over fences, or having coarse cheap netting overhead also. Let us remember what my old friend Aunt Margaret said when her chickens had a habit of getting into our front yard. She said in substance, if not in exact words, "If chickens make my neighbors to offend, I will

keep no chickens while the world standeth." And she offered then and there to sell me all the chickens if I wanted them. As I did not want them, she disposed of them soon after. In looking back at the transaction I feel sorry I did not show *my* Christianity by offering her a poultry-netting fence, and telling her to *keep* her chickens, for she was a poor woman and they were conducive to her health in getting outdoors as well as earning a scanty livelihood. Oh dear me! I am afraid I have many times in the past forgotten *my* religion and forgotten that cloak of humility that we who are followers of the Lamb should wear day and night. I keep thinking of my talk about the boys and the automobile in last issue. I once thanked a good Methodist brother for his excellent sermon, and told him it had done me a lot of good already. He surprised me by replying something like this: "Mr. Root, that sermon has done *me* good too; and I firmly believe that it always does every one good who preaches in his own way the gospel of Christ Jesus."

There is a little more I did not tell about that automobile transaction. After the boys had blocked my way in going to the prayer-meeting, on my return home I went to the postoffice to get my evening mail. Well, those boys I have spoken of have a fashion of hanging around the postoffice. I wonder if that is true of your postoffice, say in the evening, between eight and nine o'clock. While I was in getting the mail out of the drawer I heard an automobile making an awful racket as if it were going to tear itself to pieces. I rushed out; and both levers of my machine were turned up to the highest speed, and the engine was going like a young tornado. As quickly as possible I threw the levers back. Two men stood close by, talking as indifferently as if that were the way automobiles always do. I asked if they could tell me who started my machine in that way. One of them said a boy ran up and pulled the levers, and then ran back in the darkness. Then the men went on talking. I had been sorely vexed an hour before, and now my patience and Christian spirit were most severely tried. I was not only vexed with the boys who took such a liberty, but with the two men who seemed so indifferent. In fact, I was a good deal stirred up, and I do not know but I almost felt "ugly" toward everybody. I thought the two men might have stopped the boy who pushed the levers back when they saw how the engine was "racing."

Now, it looks from the above as if I were complaining about Bradentown or Bradentown men and boys, especially the two I have mentioned; but I am not. The fault was all my own. I had stupidly, if not deliberately, brought all that kind of trouble on myself. I had forgotten my Bible, my religion, and the beautiful texts at the head of this talk. Now, friends, before getting up and remonstrating, listen to me a little. If those boys had been in the habit of meddling with everybody's property, and annoying other people as they annoyed me, it would have been a different matter indeed. Public safety and well-being would have demanded, without question, that they should be taken in hand by the authorities of the town. There is a vast difference between a quarrel—that is, between two persons—and one between criminals and righteous laws. Let me illustrate. At that prayer-meeting I have mentioned, neighbor Rood spoke of a couple of farmers who had a quarrel, went to law, and kept it up, year after year, over a line fence. They wasted several times what the strip of land in contest was worth. Finally one of them sold out. A Christian man took his place. As soon as the neighbors told him about the jangle that had made hard feelings and stirred up the neighborhood for years past, he went over to see his new neighbor. After the quarrelsome man had stated the case the new neighbor said, "Look here, neighbor A. I am a man of peace. Friendly relations with all my neighbors, especially those whose lots adjoin my own, are worth more to me than the little strip of land. I am willing you should put the fence entirely over on my side *ten feet* if that will be satisfactory."

What do you suppose happened? Why, that same person who had been for years so tenacious for *every inch* of ground justly his due—the man who had *lain awake nights* in thinking it over—replied something as follows: "Why, my good friend, if that is the sort of man *you* are, I do not propose to be outdone in liberality, or, as you call it, the Christian spirit. Put it ten feet over on *my* line, and I will not say a word."

I do not need to add that a pleasant adjustment of that long-time quarrel and lawsuit was soon brought about. You see this thing is contagious; and, thank the Lord, a good spirit is contagious as well as a bad one.

Here in our town of Medina a man bought a house, and in moving it on to his lot the limbs of some shade-trees were in the way. But the owner of the trees forbade him mutilating so much as a single twig. The

house stood still in the middle of the street, and both parties consulted attorneys. The one who owned the trees neglected his work, and stood out in the street to prevent damage to his property. His wife and children joined in, and the neighbors took sides, etc. As one of the parties was in my employ I felt sure I could induce him to be reasonable. What do you think? I could not budge him an inch. He said if it took every copper he was worth he was going to have his rights. He had always been a quiet, peaceable man before. I never heard of his having trouble with anybody. I can not remember now just how it was settled. If I am correct, I think the pastors of two churches helped bring about a pleasant adjustment. And, by the way, it occurs to me right here that, when you get into a place like that, your pastor will be better (and *cheaper*) counsel than a lawyer unless, indeed, you engage a Christian lawyer; and may the Lord be praised that in these latter days there are getting to be quite a number of such lawyers. I hope they are getting *pay* for giving Christian counsel as well as the other kind.

Now, friends, what about our last text? How could the dear Savior who gave us the beatitudes counsel the use of the sword? Why, I struck upon the point exactly when I asked neighbor Rood if the boys were meddling with machines belonging to others besides myself. If the trouble that comes up is between you and your neighbor, never mind the loss of a few cents or a little strip of land. Do almost any thing for peace, and head off ugly feelings. But if somebody is making *counterfeit money*, transgressing the law, and injuring the community at large, by all *means* have him arrested. If he is conducting a saloon, and enticing the boys (and oftentimes the girls), his work is even worse than that of the counterfeiter, for he is not only robbing humanity but damaging both soul and body. Enforce the law to its utmost limit. Let there be no compromise until he gives up the business. Sometimes Satan tempts us to think that letting a man go on with his meanness is encouraging him to keep on doing so; but the petty quarrels and misunderstandings seldom come under this head. There are many people (perhaps I am one of them—yes, I am sure I am, for I have illustrated it) who are liberal and kind, but praiseworthy in perhaps every respect, but who, when they once get stirred up, get into Satan's toils and show the worst kind of disposition. They can not bear "having the fur rubbed up the wrong way," as it is sometimes expressed. The Bible is ringing with injunctions to beware of the evil one

who goes about seeking to stir up mischief and strife; and yet we forget—yes, even the best of us at times—and let the wrong spirit gain a footing. Instead of answering back when sorely tempted, let us remember who it was that said, "Pray for them that despitefully use you, and unto him that smiteth thee on one cheek, turn to him the other also." We are not only to keep quiet and steady under the fire of untrue and unjust words, but we are to be cool and steady, even if it should come to blows; for the same dear Savior says, "Your reward shall be great, and ye shall be called the children

of the Highest." Again, will it *answer* to put these precepts into practice in *business*? Let us remember that beautiful beatitude that says, "Blessed are the meek, for they shall inherit the earth." After the meek have inherited the earth, what is there going to be left for the greedy, the unscrupulous, and the quarrelsome? And, finally, if you think a Christian spirit will be a losing business in the end, read the promise away back in the Old Testament: "Five of you shall chase a hundred, and a hundred of you shall put ten thousand to flight."

Health Notes

THE AMERICAN HOOKWORM, ETC.

A good friend of GLEANINGS calls my attention to the fact that, since I have been spending so much of my time in Florida, it might be well to say something about the hookworm in the South. The *Rural New-Yorker* for Dec. 14, 1912, gives a very full description of this pest of humanity, and I wish it were possible to give it entire in GLEANINGS. When I first commenced spending my winters in Florida, seven or eight year ago, Mrs. Root and I were both shocked to find that out in the rural districts at some of the homes there were no outbuildings of any sort. At one place, where there was quite a family of young people, including young ladies, I was told the "men folks" were expected to go out among the bushes on the *north* side of the road, while the south side was understood to belong exclusively to the women folks. I am glad to tell you, however, that Florida has been coming forward by leaps and bounds in sanitary matters and sanitary precautions. The hotels and dwellings—at least to a great extent—have as convenient and up-to-date outbuildings or closets as we have here in the North. Well, now, to get back to our subject.

The hookworm, if permitted to live, will annoy and oftentimes even destroy innocent boys and girls because of this very backwoods (and I might almost say heathen) fashion of having no outbuildings. Just think of a country schoolhouse with boys and girls going everywhere without any such sanitary conveniences as I have been speaking of! Permit me to say right here, if the disease or parasite exists in the part of Florida where we are located, I have not heard of it. Manatee Co. has never had a *saloon*; and, God helping us, it never will have. But what have saloons to do with the hookworm? Just this: Where there is pov-

erty, suffering, and want, the women and children will have to go without the comforts of life. The eggs of these terrible "animals" are laid inside the body, and pass out with the excrement. If they get into the damp warm soil they will get on to the bare feet of the archin and get through the skin just as the redbugs and sticktight fleas do. Once inside, they make their way quickly to the intestines, where they are veritable bloodsuckers. Where the children play in the dirt, these eggs or minute worms get into the mouth through the food or drink. The children are stunted in growth and dwarfed in intellect from a lack of blood—blood-sucked by a hookworm in the raw intestines. Thanks to science and medicine, however, they are easily banished. Thymol in the hands of a competent physician puts an end to them; and a dose of Epsom salts cleanses the patient from the dead worms and eggs. Now, am I not right in saying that, when we banish the saloons, we shall do away with the hookworm largely? and when all the public places, and even every little home, is taught up-to-date sanitation, the hookworm will disappear.

Just one thing more: The *Rural New-Yorker* tells us that the hookworm is a near relative to the gape-worm in chickens, the colic-worm of horses, and the kidney-worm of hogs, and the dangerous trichina, which, several years ago, was so common in pork, especially ham.

STARVING AMERICA.

The above is the title of a brand-new book put out during this year by A. W. McCann, who has been in close touch with Prof. H. W. Wiley in regard to his crusade against impure food and food preserved by means of injurious chemicals. I presume our good friend T. B. Terry will smile when he sees the book I am going to send him;

for although the author starts out from an entirely different direction he ends up very close to where Terry has been working and pleading. He says in the preface that, while many books and much thought have been given in regard to the *vegetable* and *animal* kingdoms for food, but little has been said or touched on in regard to the need of our physical bodies from the *mineral* kingdom. The book from beginning to end (it contains 270 pages) is a vigorous protest against white bread, white flour, rice with the most valuable element about it left out, and the rejection in other ways of the very things that God intended we should use for food. Aside from his strong indorsement of whole wheat (every bit of the wheat) he says we need also to eat the skin of our baked potatoes; and in order to get the minerals that our bodies are often starving for, we should try to have with every meal a large proportion of "uncooked" food. Of course he urges a diet largely of fruit. While he does not enjoin or recommend a vegetarian diet exclusively, he says a little meat for the growing child once a week will be sufficient, and perhaps twice a week for adults. Let me make a couple of extracts:

Every time we boil a potato and throw away the water in which it is boiled we throw away potassium.

The despised Italian fruit-vender at the street corner is a noble American institution. By his display of greens and fruits he constantly tempts mineral-starved bodies to eat these raw and life-giving carriers of mineral salts. No one knows what a blessing the Italian has brought into the hurried, unthinking, ignorant land through his fruit-stand.

By the way, I have often assured Mrs. Root that, when we soak the potatoes over night, and throw away the water, we are wasting the best part of them. I have all my life preferred potatoes baked whole; and the most delicious part of a baked potato, when properly baked, is, for me, the skin. In the same way, I want my sweet potatoes baked without peeling, and also my *dasheens*. Before another year has passed I think a large lot of us will be made happy with dasheens. Where I have good nice apples, I have for years been eating them core and all. The seeds seem to me to supply something that nature calls for.

The book enumerates the minerals that make up the composition of the whole human body. But the author assures us we can not get these at the *drugstores*. They must come from the use of the fruits and vegetables that God prepared for us and intended us to use. The book is going to be a heavy blow at a large class of our manufacturers of food products. They not only throw away the valuable part of these

products, but substitute benzoate of soda and a lot of other injurious drugs as preservatives. The manufacturers of these prepared foods, and especially the injurious prepared foods, are making so much money in the business that they were able to throw out Dr. Wiley, even when he was proving himself to be a world-wide benefactor to the whole human race.

The book is now published by The Geo. H. Doran Co., 38 West 32d St., New York. At the present writing we are not able to give the price; but I wish that every man, woman, and child could read it.

Below is what my good friend W. P. Root had prepared for a review before I had got hold of it.

AN EPOCH-MAKING BOOK.

One of the most important contributions to the subject of health is a book called "Starving America," written by Alfred W. McCann, Member Vigilance Committee of the Associated Advertising Clubs of America. It tells why fifteen million children are physically defective; why 250,000 children die annually in this country; why we pay one-fifth as much for drugs as for foods; why 130,000 surgeons and doctors work day and night, etc. The book has 29 chapters, among which may be mentioned "what minerals do;" "white-bread starvation;" "candy, ice-cream, and other foods;" "procession of little white caskets;" "meat-eating insufficient."

It is out of the question to give here even a summary of the writer's startling exposures of the deleterious articles sold to children; and the wonder is that more of them do not die instead of stopping at 250,000 a year. The author makes a fearful arraignment of many common articles of food, some of which are not tabooed by even the pure-food law of 1906. He says that Easter eggs are made of stearic acid, carpenter's glue, glucose, coal-tar dye, and soapstone.

Licorice pellets are made of lampblack, carpenter's glue, and glucose.

Baked beans are coated with shellac.

Easter rabbits and marshmallows are made of carpenter's glue, glucose, coal-tar dyes, and ethereal flavors.

Easter chicks are made of carpenter's glue, glucose, coal-tar dyes, and ethereal flavorings.

Candy marbles are made of coal-tar dyes, glucose, ethereal flavoring, and soapstone.

As an adulterant, glucose seems to be in universal use; and, in fact, one would infer that groceries and drugs are all sold from the same shelf.

In regard to food, the book is about

equally divided between "thou shalt not eat thereof" and "thou mayest freely eat;" and in regard to the correctness of the writer's conclusions there can be no doubt.

Beekeepers will be pleased to note in this book the high estimate the author seems to attach to the use of honey. On page 181 he says:

"Honey, sap-maple syrup, and old-fashioned molasses, with unrefined cane sugar, contain the tissue salts of the cane, tree, and flower, the iron and calcium that nature put there. Such forms of sweets are natural and good. Candy prepared from them is good candy for the child."

On page 184 he recommends for breakfast, among other things, "whole-wheat bread, sweet butter, and honey." On page 186 he prescribes the same for dinner. On page 221 honey is given as a prominent ingredient in making ice-cream.

If the recommendations of Mr. McCann were to be adopted by all the people of this nation it would result in a complete revolution in our mode of life, and a still greater one in our mode of gastronomic suicide.

See also the following from the publishers:

The interest aroused by Mr. McCann's exposure of adulterated foods and their disastrous effect on the civilized races promises to find expression in reform legislation in the very near future. Mr. McCann has been personally interviewed by Governor Sulzer, of New York State. Miss Kate Barnard, of the Charity Commission of the State Board of Oklahoma, has already prepared a scheme of child nutrition which is shortly to become a part of the State scheme of education. There is every sign that the notice attracted by this book is only now at its beginning. Those who are nearest in touch with Mr. McCann and his propaganda prophesy that his book will work a revolution in child culture, and that his principles will have to be incorporated in future courses of medical training.

New York, Feb. 17. GEORGE H. DORAN CO.

Later.—Here is what Terry writes after receiving the book:

Dear Mr. Root:—The book, *Starving America*, arrived safely, and I thank you very much for it. It is really quite wonderful how nearly his teachings agree with what I have been writing for past ten years. He gives the inside of adulterations, food preservatives, etc., to an extent that makes one shudder—and all done to make more money for a few by robbing the many of money, health, and even life. Thank God that there are a few things which I can eat safely, such as baked potatoes, home-ground wheat, apples, oranges, lemons, bananas, berries, and nuts. We have been buying seedless raisins, and I believe they are all right. But last time I was in the city I saw "bleached" ones offered for sale, and people buying them because they looked so nice and white. But no sulphur-treated goods for me.

Many of the statements in the book are startling, such as that all New Orleans molasses contains sulphurous acid. What a great work there is yet for such as you and I, who really want to be helpful to the people!

Hudson, O., May 8.

Most kindly yours,
T. B. TERRY.

POISONING THE BABIES, NOT ONLY AFTER THEY ARE BORN, BUT BEFORE THEY ARE BORN.

We may rejoice that the whole wide world is waking up in regard to the matter of looking after the health and comfort of our children, especially the babies; and one can well contemplate with amazement and astonishment the indifference with which our nation and other nations treat the matter of permitting cigarettes to be manufactured and sold. Read the following from a good friend away off in New Zealand:

Dear Friend A. I. Root:—The attached clipping from the *Dunedin Evening Star* will be of especial interest to you when I inform you that Sir Robert Stout is New Zealand's Lord Chief Justice—a strong advocate of "no license," and a Prohibitionist—one who, before he occupied his present position, filled many important political positions.

Mosgiesl, Otago, N. Z. WM. CHAS. BROWN.

"What number of cigarettes do you think were sold in New Zealand last year?" asked Sir Robert Stout at the Brotherhood recently (says the *Taranaki Daily News*). Answering his own question, he gave the quantity at 794 millions. Estimating the population of the Dominion at a million, and not including all the women and children and the men who do not smoke, one could, he added, get an idea of the prevalence of the habit among smokers. "Look," he remarked, "at the enormous waste, independent of health, and yet it is totally unnecessary. It is affecting the power of our young people. Why, in America, in many of the best companies, if they find their men smoking cigarettes they tell them they are not required. They do not look upon it on sentimental grounds, but because of efficiency. Cigarette-smoking tends to make our boys inefficient, and it is the efficient race that is to survive." Continuing, Sir Robert said that, happily, the cigarette habit was not yet prevalent among womenfolk of the Dominion. Instancing the bad effect it would have on them, he pointed out that in certain parts of Belgium and France the death rate of infants was enormous. It was due to the fact that their mothers smoke cigarettes while nursing their babies. The doctors had proved the cause of the mortality by finding the narcotic in the blood of those who had died. Concluding, the speaker pointed a warning finger to the fact that, if the habit were not checked, the race would become inefficient. New Zealand could talk about its climate and what not; but it would be unable to fight the battle of nations if the habit were allowed to hold sway.

"THE HIGH COST OF LIVING," ETC.

I have read T. B. Terry's book on how to keep well and live long. It is certainly very interesting, very practical, and, if heeded by all, would solve the question of high-priced living. If we all lived as Terry claims he does, every thing in the eating line would be a drug on the market, with the possible exception of fruit. Terry does not eat in a whole day as much as almost any boy ten years old will eat at one meal. Most kids want three meals a day too.

We are a nation of 80 million people, and if we should cut out 160 million meals of one pound each, it would mean the bankruptcy of our nation.

The high cost of living is all a bugbear any way. It is nearly one-third less now than it was in 1870. We have no ground for "kicking" if we spend our money foolishly. If a man can not make a good

living, and lay by a nice little snug sum for old age or a rainy day at this very time he lacks all the true principles of frugality.

It is only the penny wise and pound foolish in our herd that suffer at this time. Their habits seem to be quite popular. They "kick" because milk is selling for eight cents per quart, which is below cost, but never "kick" at the price of poor whisky at ten cents per drink for a dozen or more friends at one time. I never could see why our saloons have more generous friends than our good milkmen or grocers who sell close and live frugally for a life time, and then do not die rich. It's the saloonkeepers who die rich. Most inconsistent is man, any way; so, what are we going to do about it?

Brewster, Wash., Dec. 14. V. W. CLOUGH.

The following from T. B. Terry, in the *Practical Farmer*, I heartily endorse, especially that part about the average city "specialist." Our readers may recall that I wasted quite a few dollars on "treatments."

HOW WOMEN CAN SAVE MANY DOLLARS.

Women pay out much money for doctors and drugs. We want to help our readers to save this to buy more of the comforts of life with. A dollar saved is as good as one earned. One of our readers, a woman of 48, has had several spells of ill health. She went to a "well-known specialist" in a city for advice. He told her that she was suffering from auto-intoxication. In plain English this means that she is self-poisoned; that there is an excessive

amount of poisons in her system, coming from wrong habits of life. He gave this sister medicine, and wanted her to remain with him for four months at considerable expense for "treatment." She at once wrote to us to get our advice about this. He told her not to eat any "fruits, sweet potatoes, corn, and lots of other good things that I am fond of. He said they brought on my troubles. My tongue is coated, bowels sluggish, and bad taste in mouth in the morning. Do you advise me to stop taking this man's medicine?" Well, what the doctor said about your condition is probably correct. But his plan of "treatment" would transfer considerable money from your pocket to his, and do you no good that you can not get at home. Yes, I advise you to throw the medicine out where even the chickens can not get it. By simply changing your wrong habits of life, nature will cure you at no expense, practically, and you can stay cured. Your tongue will then be clean, breath sweet, and you can get up in the morning feeling splendidly. The first thing to do is to eat, drink, and exercise so as to cause bowels to move loosely two or three times a day. It will take some time, but keep right at it until you do. Pardon me; but the straight truth is that the bad taste in mouth and coated tongue come largely from filth in the blood reabsorbed from constipated bowels. Nature sends this filth into one's mouth, where it can be tasted to give plain notice that the main sewer of the body is clogged and needs immediate attention. Having this matter right, be careful to furnish your body with proper air, water, sleep, and food. Then, in a word, you will probably gain by eating less, especially of protein-furnishing foods, and chewing more.

High-pressure Gardening

SEED POTATOES; HOW TO GET THEM, READY TO PLANT, BY OCT. 1, DOWN IN FLORIDA.

I have already mentioned the difficulty of finding seed potatoes ready to plant when we first reach our Florida home, say along the last of October. So far there does not seem to be any of the seedsmen or anybody else down in Florida who is prepared to furnish such potatoes, notwithstanding the best time to grow potatoes in Florida—that is, in order to have new ones about the first of the year—is in October and November. A good friend of mine whose former home was in this (Medina) county tells me how he manages it. If I am correct, he usually makes a pretty good thing of it in growing new potatoes when nobody else has them. He sends us the following in regard to his manner of doing it.

Mr. Root:—I see in GLEANINGS for April 15 that you have had trouble in raising early potatoes in Florida. For several years I have had potatoes raised for me in Medina, and shipped the first of September, so I would get them about Sept. 15, take them out under a tree or other shady place, spread them out not over two deep, cover them with grass or old sacks, throw a few bucketfuls of water on them, look at them every day or two to see that they do not get dry. They will sprout. I plant them about Oct. 1, and have new potatoes for Christmas. Potatoes should be planted in Ohio so as to have them get ripe in August; and when dug they should be spread out in a cool place to dry, then put in barrels and shipped.

West Palm Beach, Fla., April 28. J. N. PARKER.

SWEET-CLOVER GROWING IN FLORIDA NOT A DIFFICULT MATTER AFTER ALL.

Mr. A. I. Root:—I am now a subscriber to GLEANINGS, and have been, off and on, for a number of years. I am interested in all its contents, especially your department; and, contrary to the usual custom, as soon as received I begin its reading at the back to see what A. I. Root has to say. I am always interested in the different topics you discuss—particularly sweet clover. This has interested me from the beginning. In the fall of 1910 I came to Florida, and located at Taft, Orange Co., seven miles south of Orlando. The same fall I sent to your firm for a pound of white-sweet-clover seed and the "Clover Book." Both seed and book came to hand promptly. The seed was not opened until last December (one year later), when my good wife planted two 30-foot rows of it. The seed was drilled very much thicker than necessary, using for fertilizer Canada hard-wood ashes and "cowchips." It came up very thick, and made a growth of 2½ to 3 feet in height. Had less seed been used it would have grown taller. It matured the seed; and where it grew the ground is now thickly set in young clover. Last week (December 26) we drilled us a 100-foot row of the Root seed, and it is already coming up nicely. We have had this seed on hand 2½ years. It speaks well for its vitality.

It may be of interest to you to state that we live in the flattest kind of "flat woods"—raw scrub palmetto, and on this kind of land this clover grew.

I sent quite a bundle of the clover to Mr. M. K. Van Duzor, who was then editor of the *Messenger* at Orlando, Fla.; also a little write-up on sweet clover.

I am prompted to trespass upon your time with this statement, owing to your recent reference to sweet clover in a late issue of GLEANINGS, saying it had failed to grow at your Bradentown home; and also a statement recently by another writer,

that sweet clover would not mature seed the first year of growth.

With the compliments of the season to yourself and *sweet clover*, may you both "live long and prosper."

Taft, Fla., Dec. 13.

I. A. WORLEY.

My friend, we are exceedingly obliged to you; but I can hardly understand how it is that on soil so near by, and so similar, we have had so many failures. When I first came here I made a little piece of ground very rich, and planted the alfalfa and sweet clover side by side. The alfalfa came up and grew quite rank; but the sweet clover, although it did come up grew only a few inches high and never amounted to any thing. Since that, I and my neighbors around here have tried sweet clover year after year, and we have not been able to get a stand even after the seed germinates. A neighbor of mine tried liming the soil very heavily, but with no better results.

The writer of the above letter enclosed the following newspaper clipping in regard to sweet clover in Kansas:

The discovery has lately been made that a plant which grows in and around Kansas City with the rankness of a weed can be turned into vast wealth. The plant is sweet clover, which, heretofore, has been classified with scores of volunteer plants as fit for no good purpose. On vacant lots, in parkings, in back yards, this plant grows luxuriously in Kansas City, and perhaps is the most familiar of volunteer vegetation. Lately stockmen have discovered that it is "practically as good as alfalfa" as a food for stock; that it is drouth proof, and resists extreme cold; and ranchmen and farmers in western Kansas are beginning to plant it and reap great profits from it. They are paying \$10 a bushel for the seed in western Kansas now.

Recently E. G. Finnup, of Garden City, Kan., thrashed nine hundred bushels of the seed, and is getting from \$8 to \$10 a blusheel for it.

Mr. Finnup recently said that sweet clover is just as good as alfalfa for live stock; that it makes an earlier pasture and a later pasture than alfalfa, and does not bloat the cattle. It stands the dry weather and the colder weather better than alfalfa; and where there is ground that is worn out it is the best and cheapest known fertilizer to renew the soil. The best results, Mr. Finnup said, came from fall sowing.

The Kansas State Agricultural College grew four or five acres of sweet clover this year on the poorest land on the college farm, and it yielded three tons to the acre. This was as large a yield as that made by alfalfa grown on better soil. The agricultural college endorses the statement that sweet clover is more indigenous to Kansas soil than alfalfa, and that it is one of the best of fertilizers. The college is encouraging its growth in western Kansas.

It is said that the principal objection to sweet clover as a food for stock is that it has a bitter taste; but when cattle cultivate a taste for it they begin to relish it. In planting, the preparation of the ground is similar to that for alfalfa. About forty pounds to the acre is the amount usually sown.

The plant is an annual, or, in part, a biennial—it may start one year and seed the second, when it dies. In waste places it seeds itself, and the plant is renewed from year to year.

Many agricultural journals are discussing the newly discovered sweet clover, and take the position

that a new contribution has been made to agriculture.

Some of these journals say that experiments have shown that there are objections to sweet clover as a hog pasture. The roots of the plant appear to be especially palatable to hogs, and their tendency is to "root up" the sweet clover. Ringing helps considerably in obviating this trouble.

Many of the experts are encouraged to believe that very soon this plant, which heretofore has been scorned as a weed, may develop into a source of great farm wealth in Kansas and States where forage crops are of big value.—*Kansas City Star*.

THAT LUTHER BURBANK (?) "SOCIETY."

We clip the following from the *Rural New-Yorker*:

The Luther Burbank Society is still working on that devoted band of "100 life members." Nearly every day we hear from people who have been solicited. The thing that nearly lands these friends is the thought that they are to be associated through life with such people as Helen Gould and others of the rich and great. There is a list of notables who have already enlisted for life under the Burbank banner. One of our people saw the name of John Wanamaker in this list, so he wrote for further information. This is what he received in reply:

I regret to say that I do not know any thing about the Luther Burbank Society in question, except what is printed, and that I was elected an Honorary Life Member, which did not require any dues to be paid, and therefore I have not paid any. Very truly,
JOHN WANAMAKER.

It is a good chance that all the other life members except Mr. Luther Burbank would tell much the same story. Our only comment is that it seems a shame that public men will permit their reputations to be cut up and used as "sucker bait." These invitations are going to a class of people who really think they can help their business materially by associating as "life members" with these great men!

IS IT TRUE THAT A "CLUCKING HEN" IS JUST RIGHT FOR THE TABLE?

The San Francisco *Examiner* has an article to this effect. The writer says a clucking hen is always fat—in fact, that she weighs a pound more than at any other time, because she puts on flesh to prepare for the long siege of sitting. It has also been suggested that she will not lay any more eggs for perhaps two or three weeks. Now, I somewhat question whether the above is true; and I wish our poultry friends would give their opinion in regard to the matter. My experience seems to have been that a clucking hen is generally a pretty good layer. If she is broken up promptly she will soon be laying again, and so on. I have two Rhode Island Reds in my Florida home that commenced to lay when the chicks were about three weeks old. One of them never *sat* at all. I gave her a lot of chicks from the incubator the very morning she began to cluck. She took excellent care of her chicks, and before they were quite three weeks old she would excuse (?) herself and go off and lay in a stolen nest. She did this for quite a spell, still taking excel-

lent care of the chicks. This article I have mentioned says, "There is really no secret why a clucking hen is better food than any other sort;" but I must confess that I do not like the idea of killing a laying hen un-

less you have proved by trap nest or in some other way that she is a poor layer. If she wants to sit after she has laid, say, fifteen or twenty eggs, we consider it is nothing particularly against her.

Temperance

WHO SHOULD BE LYNCHED—THE BOY OR THE SALOON-KEEPER?

Of course, I do not believe in *lynching* anybody; but if the craze for lynching is to keep on in spite of us, suppose the lynchers should take a notion into their crazy heads to lynch the saloon-keeper. I suppose one reason why they do not do it is because it is the saloon-keepers who furnish the whisky that fires the crowd with a crazy zeal to make them *believe* they are defending *virtue*. Read the following, which is clipped from *Collier's Weekly*; and in submitting it I want to say, may the Lord be praised that *Colliers* have turned their heavy artillery saloonward.

THE MAN WHO MADE MONEY.

In Salem, Ill., on March 15, the most horrible crime known to humanity was committed by an eighteen-year-old boy, Sullens, against the little fourteen-year-old daughter of a well-known judge. In court Sullens was asked: "Where did you go after you left the girl?" He testified:

"I went over to the coal-mine. I wanted to get sobered up. I had drank about a pint of whisky and eight bottles of beer the night before. I got the liquor at Lakin's. I was in a car when the deputy sheriff found me."

He was saved from lynching only by the appeal of a minister who diverted the attention of the crowd to the blind tigers and bootleggers which flourish in the town.

Mr. A. Thrasher, superintendent of schools, joined the ministers and other citizens in the protests against what they described as the real cause of the crime. "That Sullens boy was in school five years ago, and was as fine a boy as there was in town," said Mr. Thrasher. "Booze is responsible for his present state."

Who are the brewers and whisky-makers who stimulated this crime and made money out of it by supplying liquor to a dealer in a prohibition town? They are probably highly respectable citizens of Peoria, where no social odium attends the making of money by the stimulation of vice.

SELLING LIQUOR IN DRY TERRITORY.

May the Lord be praised that there is "somethin' doin'." I have a colored man in my employ in Florida who has a fashion of saying, "Nothin' doin'" when our plans do not materialize—say, when the wind does not blow and the chickens happen to be out of water, etc. Well, the brewers and liquor-dealers have been enabled by their wives and millions to thwart our plans for prohibition, so that again and again comes the sad report, "nothin' doin'" in the temperance crusade. Let me now give you a little ex-

tract from the *Wheeling Advance* of May 2:

Wheeling liquor firms have been exceedingly active in endeavoring to annul the Rose county-option law in Ohio counties. Some have tried it and escaped the law; but at least one firm must send its check to Guernsey County, Ohio, for \$400 and costs if they desire to get one of their agents out of jail in order that he may continue to ply his illicit profession for their advantage.

John Frak is the man who became an unwilling guest of Sheriff Berry, at Cambridge. Frak was caught at what is known as the Wolhonding mine, near Buffalo, and from all appearances was doing a considerable business. Sheriff Berry was accompanied by Deputy Sheriff Heskett, and they lost no time in tossing John into durance vile. John was later taken before Justice L. S. Reasoner; and when prosecuting attorney of Guernsey County, B. F. Enos, presented an affidavit charging soliciting and collecting money for intoxicating liquor in dry territory Frak broke down. His plea of guilty brought him the maximum fine under the law.

This same periodical tells us of the tremendous work that is being done by Billy Sunday, Dr. Lyon, W. J. Bryan, and other great and good men enrolled in "the army of the Lord." We are also told of a car-load of beer shipped from Cincinnati to Farsas that fell into federal hands. By the way, that same *Wheeling Advance* seems to be a "live wire" in the temperance work. Its motto is, "Make prohibition prohibit, for the people's good."

"WE ARE MARCHING ON," SURE.

We clip the following from the *American Advance*:

Every day new omens of progress beckon us on. They are freighted with meaning for our cause, and they deserve our attention.

On Jan. 20th, this year, the *Chicago American*, the great Hearst daily, said editorially:

"There will never be another whisky advertisement in these columns. This paper has never advocated any thing that it believed to be detrimental to the public welfare because that it carried with it pecuniary reward. The most insidious form of influence in newspapers is through their advertising columns. . . It was forced to take this position to escape from the incongruity of opposing the whisky traffic in its editorial columns, while increasing the sales by means of its advertising columns."

I see by the January 15th GLEANINGS a person wanted your journal stopped because you had too much to say about tobacco and liquor, as he got a great deal of pleasure out of both. Well, we want you to send us your paper just because we can read the paper and not see any thing about the tobacco and liquor business except something against it.

NO. 12

Editorial

THE reader will be interested in the "good-natured scrap" between the editor and Dr. Miller that takes place in his regular department, Stray Straws, on the subject of painted versus unpainted hives.

A NEW BOOK ON APICULTURE FROM AUSTRALIA.

"AUSTRALIAN BEE LORE AND BEE CULTURE," by Albert Gale, late Bee Expert and Lecturer on Apiculture for the New South Wales Government, has come to our desk. It contains about 300 pages the size of this, taking up the whole subject of bee culture from beginning to end as it applies to New South Wales. It gives particular attention to the influence of bees on crops and the color of flowers and their influence on bee life. The book is not wholly new, but, rather, a collection of the author's published articles, or those that appeared from time to time in the New South Wales *Agricultural Gazette*. Mr. Gale is one of our occasional contributors, and needs no introduction to our readers.

A CORRECTION; DUAL INTRODUCTION.

ONE of our queen-breeders, Mr. Mell Pritchard, at our basswood apiary, calls attention to a misleading statement of ours at the bottom of the first column on page 372—at least *he* misread it, and we suppose others did. He understands that we cage all the queens at the same operation, and explains that we could not do this without having the last queen mated too old to be good for any thing. What we meant to say was that we might have two or more queens in the hive at the same time, but caged on different days. The reader will see that the language on page 372 has a double meaning. Mr. Pritchard calls further attention to the fact that we do not have more than two queens in the hive at a time, and then adds:

We do practice precaging about two or three days before the queens are expected to be laying, with good results, but we never cage two or more virgins at the same time.

HONEY-CROP CONDITIONS; CLOVER PROSPECTS.

THE outlook for alsike and white clover in the central Northern States was never better—that is to say, there is a great profusion of plants and of bloom. If other conditions shall be right we shall have a fine flow. Reports from the clover districts in the East are not quite so good. Experience has taught us that there may be times when we have plenty of bloom but no nectar. But reports in from the clover regions south of us show that the flow has been excellent. One man, one of the largest producers in the country, states that it has been the greatest clover flow he has known for many years.

During the last 48 hours we have had a cold spell—cold enough to make us fear a frost. To-day, June 9, the weather is so cold that an overcoat seems comfortable; yet, remarkable to relate, our bees are storing honey.

Further reports from California show almost a complete failure of the sage crop, although experience has taught us that when we have such failures there may be some sage honey, and the big buyers will be sure to find it.

It would be premature at this time to predict a big yield of clover honey; but if we have the right weather conditions we shall have one of the finest yields we have had for many years.

Our subscribers in the mean time are requested to send in *brief* postal card reports of honey-crop conditions and prospects. Do not write more than one or two sentences, as otherwise we can not tabulate them. These reports are important as they have a strong bearing on prices.

GLUCOSE IN "NEW ORLEANS MOLASSES."

GLUCOSE continues to be a favorite form of adulterant for syrup, as shown by "Notice of Judgment," No. 1835, from the Secretary's office of the United States Department of Agriculture. (In all such literature we notice that the product is called by its real name, that is, *glucose*, instead of the nicer-sounding assumed name, *corn syrup*.)

Four and a half barrels of molasses were seized and condemned because of being labeled in large type "Dixie New Orleans Molasses," and in small type, "Containing Sulphur Dioxide—Compound molasses and corn syrup." In the investigation it was proven that the product was not New Orleans molasses, nor was it entitled to be so called, but was a mixture containing a certain quantity of glucose. Misbranding was alleged because the product was an imitation of, and offered for sale under, the distinctive name of another article of food.

We have always supposed New Orleans molasses to be a product so cheap that no one could afford to adulterate it; but it seems from the above that glucose, unfortunately allowed to be called corn syrup, is such a cheap material that it may be profitably used as an adulterant in New Orleans molasses.

REPORT OF ILLINOIS STATE BEE CONVENTION.

THE Twelfth Annual Report of the Illinois State Beekeepers' Association, containing complete stenographic record of the entire proceedings, is before us. It contains 170 pages of closely printed matter of discussions in what appears to have been a good convention. This is followed by a brief report of the National convention.

This is the only report of any convention, National or otherwise, so far as we know, that is cloth-bound. We are advised that a copy will be sent to any beekeeper, whether from Illinois or any other State, who pays an annual fee of \$1.50, either to the Secretary of the Illinois State Beekeepers' Association, to E. B. Tyrrell, 214 Hammond Building, Detroit, or to the Secretary, James A. Stone, of the Illinois State Beekeepers' Association, Springfield, Ill.

The volume also contains the Second Annual Report of the State Inspectors, by A. L. Kildow, Putnam, Ill. This is a complete treatise on foul brood with a report of the number of apiaries visited, and a list of the counties where disease was found.

THE BAN ON BEET SUGAR FOREVER REMOVED.

In times past (and almost up to times present) a good deal of space in the bee journals has been taken up in argument for and against the use of beet sugar for feeding bees. We ourselves have been somewhat undecided at times, although so far as our own tests are concerned we have never been able to detect any bad effects whatsoever, provided the refined sugar is used.

Last spring one of our subscribers, Mr. E. L. Hoffman, of Janesville, Minn., knowing the difference of opinion in regard to beet sugar, wrote to the University Farm at

St. Paul, of the University of Minnesota. The reply which he received is so interesting and convincing that we are glad to place it before our readers at this time.

THE UNIVERSITY OF MINNESOTA.

DEPARTMENT OF AGRICULTURE,
UNIVERSITY FARM, ST. PAUL.

Division of Agricultural Chemistry and Soils.

Mr. E. L. Hofmann:—I am in receipt of your letter with regard to beet and cane sugars. I would say that, chemically, there is absolutely no difference between these two products at the present time. A number of years ago, when the beet-sugar industry was fairly new in this country, the product of the beet-sugar refineries contained a considerable amount of a substance known as betain, which apparently induced fermentation and aroused considerable prejudice against the use of this sugar. Under the present conditions none of this can be detected, and I am surprised that you found any difference in the two for your purpose, as both the cane and the beet sugar of the better grades are practically 99½ per cent pure.

We could readily determine for you the purity of the sample of sugar sweepings, but we could not determine whether it was derived from beet or cane. The station makes no charge for any of its analytical work.

R. M. WEST, Acting Chief.

St. Paul, Minn., March 29.

This statement, coming as it does from the Division of Agricultural Chemistry in one of our great universities, certainly can not be biased, and it seems to us that the question as to the value of beet sugar for bees should be settled now once for all.

DER BIEN UND SEINE ZUCHT (THE BEE AND ITS CULTURE).

THOSE who can avail themselves of German literature, and are interested in bees, will be interested in the book named above, It was written by F. Gerstung, pastor in Ossmanstedt, Germany. Mr. Gerstung is one of the most prominent beemen in Europe, and one who has been often quoted by Dr. Miller in *Stray Straws* in these pages. It is easy to say that the book has 474 pages besides a copious index, and that it contains a wealth of fine illustrations; but a thorough review of it would be almost equal to the task of writing another book as large as this.

The work in question is not only German in language but in its teachings. So far as we can observe, it is confined exclusively to German methods, with the exception of considerable space to rearing queens artificially. In this the author gives full credit to W. H. Laws, of Beeville, Texas, and to the publishers of this journal. Aside from this, however, it contains no reference to American inventions except to give the size of the Quinby and Langstroth frames. Still, to describe apiculture outside of Germany would have been foreign to the main object of the writer besides making an already large book too voluminous.

In looking through this book the American beekeeper will be struck by the great number of beautiful bee-houses, pavilions, sheds, summer-houses, etc., used in Germany, where space is so limited and lumber still more so. The American beekeeper would consider the cost of these all out of proportion to their value as bee-protectors; but as the German attaches considerable value to ornament for its own sake, perhaps the use of such buildings is warranted by the beautiful appearance they present.

Much space is given in this volume to the depredations of the wax-moth. The many illustrations show plainly what a terrible scourge the moth is there, while in this country it has ceased to cut any figure where the Italian bee has been introduced. The Germans still use, as a general thing, the old black or German brown bee.

The process of egg-laying, both drone and worker, is one of the most striking features of this book, and is splendidly illustrated by half-tones photographed from the combs direct.

On the subject of foul brood thirteen pages are devoted, describing it minutely, but not illustrating it. Its method of treatment is very complete.

We feel sure that this, the fourth enlarged and amended edition of this already celebrated work, will be of permanent value to the readers for whom it was mainly designed, and it will also be a literary monument to the skill and industry of the distinguished author.

ANOTHER CASE WHERE BEES HAVE BEEN KILLED BY SPRAYING WHILE FRUIT-TREES WERE IN BLOOM.

We have had a good many reports showing how bees have been killed by hundreds and thousands by the ignorant folly of some fruit-growers who spray trees while in full bloom. The following letter received from the New Hampshire Agricultural Experiment Station, written by the assistant horticulturist, Mr. W. H. Wolff, is pretty convincing proof. As Mr. Wolff is a scientific man, the presumption is that he would not be mistaken.

The beekeepers of this State are experiencing considerable trouble from trees being sprayed while they are in bloom. From several towns I learn of this having been done this year and last, and the few colonies we have here at the College under my care have had their strength considerably reduced owing to a commercial sprayer having sprayed 500 trees within half a mile of us while the trees were in full bloom.

The first knowledge I had of this trouble was on the morning of May 17, when, on looking at my bees, I noticed the ground in front of the hive was covered with many hundreds, dead and dying. This condition of affairs has been going on for the past

three days, until now when it has appreciably decreased the working force of each hive. I should like to know what suggestions the National Beekeepers' Association has to offer when bees are being killed off in this way. Also whether it is possible to frame a law which would protect them against the work of careless and ignorant people.

I have collected about a pint of bees from the college hives and those of a neighbor, and have dried these out. It may be that you may like to have these to analyze for traces of arsenic so as to get more exact data on killing bees by spraying the trees while in bloom.

Durham, N. H., May 22.

W. H. WOLFF.

Almost in the same mail another letter came along the same lines. It reads:

I see you want reports on spraying fruit-trees in bloom. They are spraying trees around here that are in bloom. Parties take contracts, and they spray through blooming time, paying no attention to the beekeeper's interests. Two years ago I had 40 stands of bees ruined by spraying in bloom. Two years ago there were 100 stands of bees in my community. Now there are by actual count only 25 stands. They spray with arsenate of lead and Paris green, yet they say it does not kill the bees. Even neighbors spray this year in bloom. Why not? The law says they may do so.

McGuffey, Ohio, May 11.

H. McBRIDE.

In this connection it is proper to quote the whole of what Mr. Frank Rauehuss says in the last issue of the *American Bee Journal*, page 151. Here is what he says:

Prof. Gillette says: "When the codling moth begins to appear about the time of full bloom, they do not begin to lay eggs until the majority of the apples in the orchard are one-half of an inch in diameter; when they are $\frac{3}{4}$ of an inch they are laid freely. As soon as the little apples lose their fuzzy coverings the moths lay their eggs very largely upon the cheek of the apple, but *never in the blossom*. Later they find their hiding place in the blossom end of the apple. After the blossoms have fallen and the apples have attained a little size, is the time to spray, and not before."

Prof. Gillette, who wrote the above, has raised these moths in great numbers at the Government Experimental Station, and is considered the best authority on this subject in the West.

In Bulletin No. 89, from the State of New York Experiment Station, we find the following statement: "The trees should not be sprayed while in bloom, for the spray may injure the delicate part of the flower." The Missouri State Bulletin No. 36 says: "Never spray a fruit tree while in bloom. You not only injure the delicate stigma and prevent pollinization, but you are in danger of killing bees." Bees aid largely in pollinizing all fruit trees, and with other insect life are of great service to the fruit growers at this time of the year.

Green's *Fruit Grower* says: "It is a positive injury to spray for the codling moth when the trees are in bloom." The Vermont Station prints the following advice: "Spraying when trees are in bloom is entirely useless; it is a waste of time and spraying material." The United States Agricultural Department at Washington sends out the following: "Pomologists may well join hands demanding and securing a law making it a grave misdemeanor to spray trees while they are in full bloom."

Canada has a strict law against spraying while fruit trees are in bloom. Several of our States have passed similar laws.

Spray only when blossoms have fallen. Those trees that have blossoms on them at the time of the first spraying should not be sprayed until the time of the second spraying some 12 or 14 days later.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

DR. A. F. BONNEY, *American Bee Journal*, 61, brings valuable information as to lime from J. M. Francis, a practical chemist who is also an enthusiastic beekeeper. Ordinary lime contains 10 to 25 per cent of impurities, and 100 pounds of it will absorb about 24 pints of water and 62½ pounds of carbonic acid. But after it is slaked, and in powder, it will not absorb another drop of moisture, although it will continue for some time to take up carbonic acid. So lime in bee-cellars has its time-limit.

A. I. ROOT, you object to paying 25 or 50 cts. or \$1.00 apiece for day-old chickens, but think it good sense and real science to pay \$5.00 or more for a rooster of the right stock. But what if a day-old chick turns out to be a \$5.00 rooster? I think you advise—and the advice is good—to buy several dollar queens in the expectation that one or more of them will turn out to be as good as a tested queen. Why not the same rule with chickens? If the day-old chick is of the same stock as the \$5.00 rooster—well, why not?

I SAID, p. 248, that it was not so well known that frequent changes of temperature favor granulation, and you reply, Mr. Editor, that that's just what A B C and X Y Z teaches. Yes; but are there not a lot of readers of GLEANINGS who have no A B C? And that gives me an opportunity to say to all such that they're making a big mistake. If you can't have both, by all means stop GLEANINGS for a year or two and get the book. [This matter of frequent changes of temperature favoring the granulation of honey has been spoken of several times in GLEANINGS. For example, turn to page 135, GLEANINGS for 1910. Some five or six years ago it was mentioned much more frequently than of late years.—Ed.]

I HAVE just read the report of Illinois Association, which contains a report of the last National meeting. In the Secretary's report, which previously appeared in the *Review*, exception is taken to the action of Mr. France in refusing to allow the League fund to be used for any thing but advertising. It seems to me Secretary Tyrrell can hardly be familiar with the full history of the fund. When it was offered to the National, strenuous effort was made to have it given without any string to it, and it was just as strenuously insisted by the League that the National use it solely for advertising or not get it at all. The National received the fund on that basis, and it would

be a breach of good faith now to divert the fund to any other purpose. Nor is such action at all justified by the consent of all but one of those who contributed more than \$25.00 each. If all should consent except a single one who had contributed 50 cents, that one would have a right to protest that it would be wrong to divert the money to any other use.

Mr. France would have less ground to stand upon if it were impossible to carry out the original intention. But at that same meeting at Cincinnati, it was practically resolved that the National should do the very thing that the League fund was intended to pay for. Mr. France is the only living member of the committee appointed to spend the money. If two such men as he and Secretary Tyrrell were appointed a committee, with free hand to use that fund as originally intended, it seems it might do more good than used in any other way. Why not? [Excellent suggestion! It seems as if this might be the solution of an unpleasant problem. GLEANINGS respectfully refers it to the parties interested. If Mr. Tyrrell and Mr. France can agree on a propaganda of advertising, we see no reason why the fund could not be used. Judicious advertising in the magazines, and perhaps the newspapers, showing the real value of honey as a food, would benefit the industry at large.—Ed.]

THAT'S right, Mr. Editor; "jab" when you get the chance, p. 328. You ask if I'm *sure* it's economy not to paint hives. No; the list of things I'm not sure about is about as big as the list of things I don't know. You want to know whether unpainted hives don't gap at the joints sooner than painted ones. I don't know. I haven't kept any till they gapped. I've kept them only since the first dovetailed hives were made, and they don't gap yet. How soon do your painted hives gap? You ask about covers twisting and checking. Now look here. Did you ever know me to advocate unpainted wooden covers? But with a very few exceptions my covers are covered with something better than paint. Some of them are covered with tin that's painted—at least it was painted—but the majority are covered with zinc, which doesn't need paint. You have never made better covers. You ask if it's economy to leave houses unpainted. I don't know. Depends on the cost of new siding when the old wears out, and the cost of keeping the houses painted during the same time. Now that we've discussed economy, perhaps,

enough, it might not be out of place to say that it might trouble you to prove that I ever said it was economy to leave off paint. It was *you* that gave economy as my reason—not the first time I've been libeled. But if you go to hunting up proof I'll help you enough to refer you to "Fifty Years among the Bees," p. 80, where I say, "I suppose they would last longer if painted, but hardly enough to pay for the paint." My real reasons still remain: Doolittle and the health of the bees.

I've just been down through the apiary, and I didn't find a single hive with gapping corners, nor even with the least inclination toward it. I mention this, not because of its bearing on the above controversy, but because, years ago, so much was said against dovetailed hives because the corners would not stand. If mine are still perfect after all these years without paint, it hardly seems a valid objection. [We accept your correction in regard to the covers. You remind us that you have always advocated the painting of these when made of wood. We admit that the dovetailed hives will not gap at the corners, even if unpainted; but a large number of people use hives not lock-cornered nor dovetailed—some factory-made and many home-made. Shall these people be encouraged to use paint? and is it not true, doctor, that, before you began using dovetailed hives, your old unpainted hives that were not dovetailed, gapped at the corners? If so, was it because of a lack of paint? But aside from the economic side of the preservation of the hives, is it not true that an unpainted hive assumes a gray-black hue—a color that becomes almost pure black? Such hives out in the sun will often drive the bees out of them, and stop honey-gathering altogether. Some years ago, as you may recall, we tested out on a hot sunny day the external temperature of the wood of old unpainted hives, some painted venetian red, and some painted with two coats of white lead. The day selected for the test was very warm—between 95 and 100 in the shade. We placed the bare hand on the white painted hives, and found the surface was merely warm, while the surfaces of the dark hives were almost hot enough to blister the hand. Colonies of the same strength were contentedly working in the hives painted white, but were clustered out badly in front of the dark ones. We can not now recall the difference in temperature, but it was considerable.

It may be argued that an unpainted hive should be kept in the shade; but does not experience prove that shade is detrimental to the early spring development of a colo-

ny? While we have not definite figures to show, is it not also true that, other things being equal, a colony in a painted hive out in the open will work more hours in the 24 than one in an unpainted hive? If the latter were kept in the shade, the variation might not be great; but would that colony in the shade be as far along as one out in the open where the sun could get it? If we remember correctly, Mr. E. W. Alexander and other prominent beekeepers have made the statement that a shaded colony will not fly out as early in the morning nor be as strong at the beginning of the honey-flow as the one out in the open.

This is a fruitful subject for discussion. It is not a question whether Dr. Miller, the editor, or anybody else is right; but it is a question for the beekeeper to solve, whether there is economy in the use of paint, in the greater durability and the condition of the colony for honey-gathering at the beginning of the honey-flow. Dr. Miller and the editor are both willing to be "jabbed," providing the truth can be brought out.

That Dr. Miller might have the "last say" or last "jab" we submitted the foregoing to him, and here is his reply.—ED.]

I've read over what you say more than once, Mr. Editor, have studied it carefully to find a weak spot where I could give you a jab, and find you so strongly entrenched that I feel a good bit like surrendering unconditionally. Yet I have something of a fasthold in the winter welfare of the bees. As my cellar is now warmed, I think it would make little difference—perhaps none—but before the furnace was in it I think damp and mold could be so much worse in the painted hives in winter as to make up for the advantages of paint in summer. I may also offer that in my dovetailed hives that have failed through age the first failure is nearly always at the edges, inside rather than outside, where no paint is applied in painted hives.

In my possible downfall I may take a grim satisfaction in reminding you that you failed to give one argument on your side. You say bees don't begin work so early in the morning if their hives are in the shade; but you failed to say that bees in the shade stop work earlier in the evening. I had marked proof of that when in former years bees were brought out of the cellar and the bees of the out-apiaries were massed temporarily northeast of the shop. In the evening there was a plain line of demarcation, each colony ceasing its flight just as soon as it came into shadow. If you had any gratitude about you, you'd give me a nickel for furnishing this missing argument.

SIFTINGS

J. E. CRANE, Middlebury, Vt.

Wesley Foster's advice about tinkering with American foul brood is thoroughly sound, and every young or inexperienced beekeeper would do well to heed his advice. See page 142, March 1.

* * *

That method of ridding cappings of honey by centrifugal motion, by Mr. D. R. Hardy, and described by Mr. Holtermann, page 188, March 15, would seem to open the way to rid the cappings of most of the honey that sticks to them. It will be remembered that this is the way sugar is treated in refineries to rid it of all superfluous molasses or syrup.

* * *

A good deal has been written of late about bee-veils. I have many times wondered if we could not have a special kind of wire cloth for this special purpose, with meshes say $\frac{1}{8}$ inch instead of 1-12 or 1-14 as at present. This would reduce the obstruction to vision from a third to nearly a half, and give a freer circulation of air. [We already have such a wire cloth. The wires are $\frac{1}{8}$ inch apart.—Ed.]

* * *

P. C. Chadwick makes a good point on p. 140, March 1, where he concludes that pollen is of more importance in stimulating bees to breed in springtime than the feeding of thin liquid sweet where they have enough honey stored in the hive. Last March, on the east coast of Florida bees built up readily, although they gathered very little or no nectar, and were growing lighter all the time; but they found an abundance of pollen. "Pollen is a greater aid in that direction than additional stores," he says, and he is right.

* * *

It seems to me that the March 1st issue was, on many accounts, one of the most interesting numbers I have seen in a long time; and any one who shall say hereafter that women can not be successful beekeepers may be counted as not up to modern ways of business. I doubt if an equal number of articles written by men twenty or twenty-five years ago were more scientific or up to the best methods now known than these written by women from their own experience. One can not wonder, when he sees how well women have come to understand and to practice the art of beekeeping, whether the men are not going to turn this work over to them, as they have to so great an extent the rearing of poultry. However that may be, I feel that this number marks a

new era in beekeeping, or at least one not realized before.

* * *

THE OLD QUESTION OF GRADING COMB HONEY.

In the report of the National Beekeepers' Association at Cincinnati I notice that the question of grading was a live one. Evidently this question has never been settled right or it would not be bobbing up continually. Now it seems to me that it would be well to mention here a few facts or what appears to be such. The first I would speak of is that, the closer the lines of grading are drawn, the more beekeepers are turning their attention to extracting their honey, where grading is not so difficult. Mr. Muth would have only two grades—fancy and No. 1. But how much profit will it be to the beekeeper who produces comb honey when he finds he can not sell more than half his crop because it will not come up to these grades? We are not surprised to learn that there is a scarcity of comb honey on the markets. It is easy to see that it would be more convenient for the honey merchant, like Mr. Muth, to have but two grades of honey. It would be even better for the beekeeper to have only one; but, taking the country as a whole, the bees do not all put up honey that way. I think we might make twenty grades quite distinct and easily recognized. These would all merge from one into another so as to be almost imperceptible in some cases, but yet each as a class would be quite distinct from the others.

Now the question is, How can this great variety be classified so as to suit best the trade and consumers? Shall the beekeeper sort out a little of the best, and call it "fancy," and a larger amount and call it No. 1, and melt up the rest? or shall he sort it out so the cases he puts up can have some one, two, or three words that will accurately describe it, each case being of a kind? I believe it is the business (I almost said duty) of the merchant to find a market for the off grades of honey as well as the "fancy" and No. 1. When the oil-refineries found they had an immense amount of gasoline, of so little value that they let it run to waste, they set men to inventing stoves that would consume it, and then engines that would use it for power, until today the demand is such as to bring great profits to refineries. Now, I believe there could be an opening made, or a demand at a fair price for all our grades of honey that are fit to put up, and yet that will not grade No. 1 or "fancy."

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

A NUMBER OF QUESTIONS ANSWERED.

Instead of reproducing each inquiry and answering each question separately, which would take more space and yet not give any more information, I am incorporating all the answers into a short article. These inquiries, from four different persons, are all on the subject of bulk-comb-honey production, some of the questions being identical, while others are entirely different. Many inquiries are made for a booklet on our method of management, the hives we use, and on the matter of using the divisible-brood-chamber hives, and the production of bulk comb honey. To this we shall have to reply that we have no literature on any of these subjects other than what the bee journals have so kindly given during a period of fifteen years or more, although we have been requested several times to have such booklets published for the benefit of those who are seeking information. Our time has been so much taken up that we have not even given the matter serious thought, and consequently do not know whether it would be advisable for us to do so.

THE HIVE WE PREFER.

The most frequently asked question is in regard to our preference of the hive to use in connection with our methods of management, especially for bulk-comb-honey production. It is already well known that our long years of experience with different hives has given us an opportunity to test the divisible-brood-chamber hives to a finish; and since we have had the best results with them we prefer them. They are composed of shallow supers known as the Ideal shallow extracting-supers, of the ten-frame size, with shallow Hoffman frames, $5\frac{3}{8}$ inches deep, as listed in the supply-dealers' catalogs. Our frame has a heavier top-bar, however, $\frac{1}{2}$ inch thick. It is narrower also than the regularly made top-bar, or $\frac{7}{8}$ inch wide. There is no comb-guide or groove for the foundation, as this is fastened with melted beeswax.

BURR-COMBS

The foundation is used in full sheets, of the thin-super grade, and without wires always. This grade of foundation is just right, and heavy enough so that brood foundation is not necessary in these shallow frames. The same supers or *shallow stories*, as they ought to be called, are used the same way throughout for brood-chamber and supers—a great advantage on account of the interchangeability. There is no trouble about too many burr-combs between the several stories, or the frames of one story

and those of another, in our manipulation of this kind of hive. It seems that beekeepers often allow their colonies to become too crowded, and hence experience this trouble. Colonies always allowed room as needed will have little occasion to build between the bottoms and tops of frames of one story and another. Proper manipulation of the several stories, and interchanging with another from below to above, and *vice versa*, which is necessary to accomplish the best results, never allows the stories to remain so long in the same position as to encourage serious burr-comb buildings. Our narrow, thick top-bar is no more, if as much, subject to cause burr-comb building than the thinner and wider top-bars regularly furnished. The latter are more subject to sagging, however, and often there are more burr-combs, as a consequence.

THE VALUE OF SHALLOW EXTRACTING-SUPERS.

With several hundred shallow extracting-supers on hand, the beekeeper has a valuable investment, and is better prepared for bulk-comb-honey production than if he did not have them. By no means would I cut out these valuable combs and melt them into wax, having to fill the frames with full sheets of foundation for bulk comb honey. These supers should be placed on the regular brood-chambers early in the spring. First, to allow more breeding room for the colony, meaning a stronger colony for the honey-flow later; and, second, it furnishes a place for the bees to store the first scattering honey that comes in before the main honey-flow begins. We use these supers, one over each brood-chamber proper during the entire winter. In fact, this super is, with us, part of the brood-chamber until the honey-flow begins. Just before the honey-flow comes on, this super or upper story is raised up, and the new supers with frames filled full of foundation are slipped in between it and the brood-chamber. Tiering up as with section honey is then continued, and this is one of the best ways to induce bees to begin work, and work with great energy in the supers immediately upon giving them. The extracted honey out of the upper or first super with the shallow extracting-combs, is used for putting up the bulk comb honey, hence is that much profit. The same super is again used after the main honey-flow to catch that honey, which would not be enough to warrant putting on another comb-honey super, and likewise goes for extracted honey, as a great deal of it is needed to put up a good crop of the comb honey.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

PROBABLY SAC BROOD INSTEAD OF BLACK BROOD.

I submit the following extract from a letter just received from Mr. J. D. Bixby:

Your Mr. Meeker, County Inspector, is laboring under some misapprehension as to *black* brood. Several parties have been down, and others have written me, and I have also seen fresh samples from four hives in two apiaries, which he had pronounced black brood, which are distinctly *not*, but are unquestionably a bad form of pickled brood or sac brood as the Department calls it. The same also prevails in parts of Riverside Co., and about Lordsburg and Pomona. I had a man here from Pomona yesterday with samples which seem to be worst where the honey-flow has been light.

It is some relief to hear that there is even a possibility of our not being so close to the disease as has been reported. Mr. Bixby is a man of wide experience with this disease, and it is very likely that he is correct, as Mr. Meeker has not had to combat the disease, and has not lived where it has prevailed.

* * *

WHAT TO DO FROM NOW ON.

The problem from now on that will absorb the mind of the California beekeeper will be how to manage the bees with the least possible expense, and keep them in the best possible condition. Some will have the foul-brood question to give them additional concern. Near the coast some will doubtless turn toward the bean-fields for relief, while in the foot-hill region there are those who can go higher in the mountains for relief, the main object being to keep the bees in good condition in anticipation of a honey-flow next season. Nine years ago my uncle and I hauled five loads of bees into the Julian Mountains (a distance of ninety miles) to summer them. They were not returned until the following April, but came back in fine condition, and averaged 240 pounds per colony for the season. There are many places nearer that I believe would be just as good. But we can not all go. In fact, the great majority of us must stay where we are and work out our own salvation.

In the natural course of events eight months must pass before we can expect relief, four of which will be during the hot summer. Then we may have a repetition of the season of 1905, with an open wet winter allowing the weak colonies to build up rapidly, to our great delight.

Honey will doubtless be sold at a good price, and there will be great temptation to take every thing found above the brood-chamber. In fact, it is now bringing 10 cts. a pound for white. The feeding-back of sugar is the plan of those who take all

in sight. This I believe to be false economy, for it will not be possible to secure the same results from a pound of sugar that one would get from a pound of sealed honey. Then, again, sugar may not be as cheap later as at the present time, for it is sure to advance during the fruit-canning season, and may not return to its present level. Even if it should, it is not the equal of honey for breeding purposes.

Many have already extracted all old honey from their supers to prevent it from blending the new crop into a darker grade. This must be fed back or sugar used in its stead.

I have been so doubtful of the season from the beginning that I removed the old honey, but did not extract it, and have now returned it to the hives, placing two supers over the strongest colonies with an excluder below. It will be left there until the weaker colonies need it, then it will be given to them in the comb. I prefer to carry the combs over by storing them on the strongest colonies, for the reason that they are better able to protect it from moth and robber bees where it contains honey. I never make a practice of sulphuring combs for the purpose of keeping moths out if there are bees sufficient in the yard to protect them through the summer months. They may be removed late in the fall and stored until needed in the spring, and thus avoid the disagreeable odor of sulphur.

Usually breeding will not entirely cease if there are plenty of stores on the hive, and in consequence it is not best to let a colony get too low in stores, but to take combs from the stronger ones and give to the weaker ones before they begin to be poverty-stricken, and thus encourage normal breeding. The season may not be as bad as I anticipate; but it can not be very good for breeding purposes after the hot weather sets in, for what little green vegetation there is in the foot-hills will soon be parched and dry from the hot summer sun, and the chances are that in many sections of the foot-hill region we shall find our colonies very much run down by autumn, for many are none too strong now.

Have courage. This is not the first period of the kind California has seen, and will not be the last; but there will be good periods between, and some day we shall realize more for our honey crop than we could sell the bees for at the present time, with interest at 6 per cent added. It is no time to get the selling fever; but in my opinion it is the very best time to buy.

Conversations with Doolittle

At Borodino, New York.

WAX SECRETION AND COMB-BUILDING.

"When may we expect that the bees will secrete wax and begin building comb?"

"Among some of my early recollections is this from L. L. Langstroth's work on bees: 'It is an interesting fact which hitherto seems to have escaped notice, that honey-gathering and comb-building go on simultaneously; so that, when one stops, the other stops also. As soon as the honey harvest begins to fail, so that consumption is in advance of production, the bees cease building new comb, even though large portions of the hive are unfilled. When honey no longer abounds in the fields, it is wisely ordered that they should not consume, in comb-building, the treasures for winter use.' In addition to this I would say that, under the same circumstances, the higher the temperature up to 90 or 95 degrees in the shade, the better results. This is in harmony with all general affairs as they naturally take place. Warm weather being necessary for the secretion of nectar, it is but natural that the bees should go out in search of it, and with the gathering of more honey than is needed for the economy of brood-rearing, wax secretion invariably takes place when more room is needed.

"What is the estimate in pounds of honey necessary to make one pound of wax?"

"This has been variously estimated at from six to twenty pounds. I think it was Huber who first gave the estimate of twenty pounds; but, if I am right, his statement was made after confining the bees and feeding them honey. This, of course, put the colony out of a normal condition, under which circumstances more honey would naturally be consumed owing to the bees becoming agitated through their struggle for freedom. Others, who estimate as low as six pounds, think that pollen helps in the secretion of wax, and a high temperature is considered an important factor, on the principle that it seems to take much less food for hogs to put on fat in warm weather than in cold. Others think that, in addition to temperature, the freedom from vigorous work in the fields has very much to do with the matter. With a partially enforced idleness bees will secrete wax and build comb very fast. There is hardly an apiarist in the world who has not noticed with what alacrity comb-building is carried on by the newly hived swarm previous to extended brood-rearing. With a high temperature and almost perfect immunity from other duties, wax secretion is carried on most economically."

"With a hive partially or fully filled with comb, when does wax secretion begin?"

"Generally, not until all available cells are filled to an extent consistent with the evaporation of moisture contained in the nectar brought in from the fields by the field bees. Up to this time all repair work about the hive and comb requiring wax is made at the expense of other portions of the comb already built, as is invariably indicated by the color. The beekeeper who has not noticed this is an exception and not the rule. Put an empty frame having only a starter down at the side of the outside comb of the brood next to the brood-nest, and see how it will be filled with comb of all shades and colors. Then look at queen-cups and queen-cells as they are being built. These always correspond in shade with the comb upon which they are constructed.

"It is rightly claimed that there are times when *wax secretion is imperative*. Years ago Prof. Cook found that, during the height of a profuse nectar flow, wax scales could be found upon the field bees which were visiting the flowers. With plenty of empty cells comb extension is unnecessary, either for breeding purposes or the storage of honey. But with a good nectar flow, and all available cells filled, the field bees transfer their loads to the comb-builders and nurse bees, which, being unable to disgorge themselves, are compelled to secrete wax the same as a new swarm does when without comb. Under both conditions comb extension is desired. With the swarm this desire can be satisfied, but not with the other. Close observers have noticed that, toward the close of a day when the nectar secretion has been exceptionally good, so that the nurse and comb-building bees are gorged almost to bursting, the old field bees have been compelled to keep their loads, and will cluster out on the hive with plenty of nectar still inviting them to a sumptuous feast. At such times, after 24 hours the old fielders can be found bearing wax scales, even though these scales are generally confined to the comb-building bees under most circumstances. Hence it is easy to see that, with such an exceptionally good flow of nectar, there must come a waste of wax with a hive and supers filled with fully occupied combs; and under such circumstances, where foundation is given, the sheets are not disturbed at all. Then it is that the bees build combs by adding their wax to the foundation, thus giving a heavy base or midrib to section honey."

General Correspondence

A NEW OLD TREATMENT FOR AMERICAN OR EUROPEAN FOUL BROOD

Trapping the Bees Away from the Old Combs by Means of a Bee-escape

BY W. W. CASE

[Last winter we attended a convention of the Pennsylvania State Beekeepers' Association that met at Harrisburg. Among others, we had the pleasure of meeting Mr. W. W. Case, whom we had long known by correspondence. In a paper he read in that convention Mr. Case gave this method of treatment; and as he and his friends have had such excellent success with it, we asked him to prepare a special article with drawings for GLEANINGS, describing the method, and here it is.—ED.]

After more than twenty years of contact with and study of both American and European foul brood, I have evolved, and am at last ready to give to all beedom, a safe and sane treatment that renders the terrors of foul brood one of the least problems in successful apiculture—far less than that of always successfully wintering—a treatment that will not interfere with the work of api-

2. Any infected honey stored in the combs during treatment will always cause a recurrence of diseased conditions.

3. Normally, bees always leave the hive with empty honey-sacs.

4. Bees on being disturbed in the hive always give more or less honey to their fellows, which, after the disturbance is over, is placed by the field workers in their handiest cells before they again go to the fields.

5. At the commencement of treatment there must be no comb in which honey may be stored.

From the above five principles I have been able to evolve the following treatment, which is just as safe in the hands of the amateur as of the expert, and without the loss of colony, brood, honey crop, danger from robbing, or spreading the infection in any way. It applies equally well to both forms of disease.

Infected colonies in early spring may, if not too far advanced in a diseased condi-

W. W. Case's method of allowing the bees to pass naturally and quietly away from foul-broody combs through a tube bee-escape.

ary inspectors in the least, but will prove a boon in solving their problems. In fact, it already has the unqualified indorsement of inspectors in Pennsylvania and New Jersey; and while I have bred by selection a strain of Italians absolutely immune to European foul brood, the treatment for infected colonies is the same for both kinds, and is based on the five following principles worked out and successfully proven in my own apiary, while surrounded, even today, by the most rabid infection of both kinds of disease.

FIVE PRINCIPLES.

1. The adult bee does not carry infection while digesting infected honey.

tion, cast normal swarms, especially if confined to the hive-body, in which case the parent hive should be set to one side a few inches, and the swarm hived on full sheets of foundation on the old stand, after which remove all queen-cells from the hive which cast the swarm, return the combs, and close the hive bee-tight. Next bore a one-inch hole in the end of the hive, over which nail a one-inch tin-pipe bee-escape about six inches long, and tapering to a point just large enough for a single bee (including drones) to pass out at a time, and place the hive in position shown in the cut with the small end of the tube about two inches in front of and above the entrance. It is

imperative that the infected colony hived on foundation (or starters) on the old stand be not disturbed under four (and, better still, five) full days; for when the bees start to the fields after hiving, the wax-workers will take all the infected honey brought from the old hive, and, if left absolutely alone, will digest it all in forming wax; but if disturbed before four days so as to exchange honey, they will, before again going to the fields, place the honey, now probably infected, in the first cell the bees have drawn, instead of giving it to the wax-workers, when it will be fed to the first brood that hatches, thus at once reinfecting the colony. Should it become imperative, from any cause, to break the wax cluster before the fifth day, all comb built must be removed, and fresh foundation given. In the course of about four weeks all the brood in the hive with the pipe escape will have hatched and passed out, and united with the parent colony; and as all have left the hive with empty honey-sacs there is absolutely no danger of their carrying the infection. It is, perhaps, needless to say that the piped hive must in no wise be disturbed until the last bee has hatched and passed out, when it can be removed to a place of safety, and the wax rendered at leisure.

Colonies that do not swarm can be shaken on foundation in a clean hive on the old stand, the hive sealed bee-tight, and piped out as before. In shaking, it is best to leave enough bees to care for the unsealed brood, as they will pass out and unite with the treated colony in a short time any way.

Colonies in box hives, whether diseased or healthy, can be drummed out and transferred with the pipe, with no danger of robbing, infection, loss of brood, nor drone brood to dispose of. Neither does it necessitate smashed-up hives and the general muss accompanying transferring, and the wax rendered by a good press will far more than pay for the foundation used.

I have still to learn of a single failure in the cure of foul brood by the above method absolutely carried out, either in my own apiary or in those of others who have used the method.

Frenchtown, N. J.

[This plan is not new, neither is it old. The basic principle was given by Mr. M. M. Baldrige, of Illinois, in 1894; but Mr. Case's modification of it is new. The old original Baldrige treatment was much the same as that given by our correspondent above, with this difference: Mr. Baldrige put a new clean hive on the old stand. In this hive he placed a frame of brood and bees from a healthy colony, and the queen

from the diseased colony. The queen is of course caged for 24 hours. The rest of the space was filled with frames of foundation. The old hive was set to one side, pointing in the same direction, and as close to it as possible. In front of it was attached a bee-escape consisting of a tapering perforated tin tube, all other means of egress being closed. The perforations of course were too small to admit bees. The flying bees and hatching bees, as fast as they would come out of the parent colony, would go into the new hive on the old stand. The old hive was relieved of its bees and brood, leaving nothing but combs and honey to be melted up.

It will be observed that the Case modification is much the same, except that his tin tube has no perforations. It is six inches long, and just large enough to let one bee or drone through. Mr. Case explained to the writer that perforations have a tendency to attract robbers; that the solid tin tube, with its opening so far from the parent hive, does not draw robbers.

The Case method has the further advantage that it delivers the bees, young and old, to a point immediately in the center and in front of the entrance of the hive on the old stand, and as fast as young bees hatch out from what brood may be healthy, they reinforce the swarm. By this treatment no healthy brood is lost; and as the average of diseased colonies will contain only a small percentage of infected brood, there will be but very little loss through the treatment.

The only caution we wish to offer is that the parent hive be properly shaded if the treatment is applied in hot weather. We have had reports from those who have tried the Baldrige treatment, showing how combs were melted down because of the contracted entrance through the bee-escape. The *solid* tin tube would be worse in this respect than the perforated tube. It will be simply impossible for bees to ventilate a hive exposed to the hot sun with a solid tin-tube bee-escape attached as in the drawing. If hives are in suitable shade, or if the weather is not excessively warm, the treatment will work as described by our correspondent.

This treatment, or a modification of it, has the endorsement of the Bureau of Entomology—see Bulletin 442, by Dr. Phillips, subhead "Treatment with Bee-escapes."

From the fact that we have heard excellent reports from the modified Baldrige treatment, we have no hesitation in recommending it to our subscribers, providing the weather is not hot nor the hive exposed to the sun.—ED.]

THE VARIOUS PHASES OF THE SWARMING PROBLEM CONSIDERED

Caring for the Brood from a Shaken Swarm; Removing the Queen and Destroying the Cells

BY DR. C. C. MILLER

[A short time ago in one of our letters to Dr. Miller we expressed the wish that he would tell us more fully than he had explained in the various 'Straws what he knew about the prevention of swarming for the production of comb honey—that is to say, we desired him to give us in an article his latest revised ideas on the subject. Probably no man in the United States who is a producer of comb honey has given this more earnest and thorough attention than the sage of Marengo. The article will speak for itself.—ED.]

I am requested by the editor to tell what is the best way to prevent swarming. I don't know, because there may be some plan that I know nothing about that is away ahead of any thing I know. But as I have been fighting bitterly against swarming during my whole beekeeping life, it may be that I can say something that may be useful to those of less experience.

Swarming can be prevented—at least for a time; but I question whether there is any profitable plan of treatment that will allow us to say: "There is a colony which has been so treated that it is absolutely certain not to have any thought of swarming during the present season." Even when a colony throws off a natural swarm, although the rule is that (leaving out of account after-swarms) neither swarm nor mother-colony will swarm again till another year, yet there are exceptions to the rule. But those exceptions are so rare in most places that if they should all be allowed to abscond the loss would not be great. It is probably safe to say that a colony can be so managed that it will be just as safe from swarming as a colony that has already swarmed naturally.

One plan of such management is the well-known one of shake swarming. This is really anticipated swarming, as the plan is merely to take away all brood, leaving the bees in the condition of a natural swarm. As the bees sometimes desert when left entirely without brood, one frame of brood may be left for three or four days, or until the queen gets fairly started in one or more of the other frames. It has the advantage over natural swarming, besides other advantages, that *all* the bees may be left with the swarm. It has, however, the disadvantage that taking away the brood weakens the colony by just so many future workers. It may be urged that bees do not go afield till 16 days old, and so it will be from 16 to 37 days before the bees from this brood will become fielders—too late to count much on the harvest. But the harvest may last

beyond that. Besides, the department of labor in which a worker engages is not altogether a matter of age, but depends to some extent on the needs of the colony. Each young bee that emerges to-day may liberate one of its older sisters for field-work, whether that older sister be more or less than 16 days old.

But with shake-swarming there is a way of recouping half the loss caused by taking away brood. When the first lot of colonies are shaken, say half or less than half of the apiary, pile up the beeless brood three, four, or more stories high, over colonies that need not be very strong. Then eight days later, when the brood in these piles is sealed, shake a second lot, and, instead of giving them empty combs, give them the sealed brood from the piles, shaking off all the bees in front of the hive which was under the pile. So far as I have tried it, these frames of sealed brood work just the same as empty combs.

It is often said that a queen of the current season's rearing will not swarm until she has wintered over. That depends. If a colony is fully in the swarming humor, having cells well started, and the old queen is exchanged for a young one, the colony will just as promptly swarm with the young one, even though she may not have been laying a week. But if by any means the colony becomes queenless, and rears its own queen, or if a ripe cell be given when it is made queenless, the resulting young queen will not swarm that season. In general, if a colony be kept ten days without a laying queen, and a young queen be then given, either a laying queen or a virgin, there will be no swarming. But it must be remembered that rare exceptions with these young queens will occur. They are probably more likely to occur with Italians than with blacks. The later in the season the young queen is reared, the less likelihood of an exception.

A way, then, to prevent swarming is to remove all queens (at the beginning of the clover harvest in clover regions) and ten days later destroy all queen-cells but one. Or, better still, destroy *all* cells, and give a young laying queen.

For those who are desirous of improving their bees, this plan of never allowing queens more than a year old has a serious objection. It gives no adequate opportunity to test the value of a queen as a breeder, for the credit of a crop must be divided between the two queens that have furnished the workers. A compromise plan must then be followed, and the one generally followed by the writer may here be given.

As soon as there is any suspicion that the

THE BOSTON IVY AS A HONEY-PLANT

BY A. S. KINNEY

While talking with a neighbor one day mention was made of some honey which he had purchased from a Mr. X in an adjoining town. "This honey," he said, "had such a strong odor of the horse-stable that they could not eat it." Knowing the location of Mr. X's apiary as I did, and the careful kind of man he was, I knew at once that the odor was not that from the horse-stable, but probably from a certain kind of nectar which the bees had collected. Having never seen in the bee journals any mention of the plant which I presumed was the cause of the offensive odor of Mr. X's honey, as he lives near where there is much of it I have thought perhaps the readers of GLEANINGS would be interested in the following observations which I have made upon the Boston ivy (*Ampelopsis veitchii*) of the florists.

This vine was introduced into this country a number of years ago from Japan, and at once gained great popularity because of its hardiness and rapid growth. It is especially adapted to use upon stone and brick buildings, and wherever one finds such buildings in the Northern States they will usually be more or less covered with *Ampelopsis veitchii*.

Where an apiary is located near a city or village where there are mills, often there are acres of the plant within range of the bees. This may be a most desirable state of affairs, as it is in this especial section where my apiary is located, while in other sections, where there is a mid-summer flow of nectar, it might prove a very serious objection. From my own observations, however, it appears to me that the chances are more in favor of the ampelopsis being a help than a hindrance where it forms a part of the bee pasturage. In my own case, now that I know how to take care of the nectar when it comes in, I find that the ampelopsis fills in

a considerable time when the bees would be idle, probably hanging on the front of the hives, or, worse, trying to steal from their neighbors.

The ampelopsis usually, in this region, begins to bloom between the 15th and 20th of July, at which time the clover-flow is about over, also locust and basswood. These plants often continue in blossom four to six weeks, those upon the north side of buildings coming into blossom more than a week later than those on the south side. The bees are very fond of the nectar from these flowers, simply going crazy over it. Although they often collect more than they need for immediate use, and store it as surplus, it is very difficult for me to get any considerable quantity pure, as it is more or less mixed with other kinds of nectar, especially white clover, my bees having access to several acres of lawn upon which there is considerable white clover all summer. The bees work upon the white clover in the morning, as there seems to be no flow of nectar from the ampelopsis until about noon. After this flow begins one will seldom see a bee working on any thing else. This flow usually continues until nearly night, and during this time one would think by the sound that there was a swarm in the vines. In

The familiar Boston ivy, *Ampelopsis Veitchii*.

W. C. Waller, of Wiggins, Miss., with a prime swarm that issued March 25. The bees conveniently clustered on a limb from a fig tree that had been thrown over a fence.

fact, I have been notified twice by persons hearing the noise that my bees were swarming.

So far as I have been able to observe, I do not find the honey from this plant objectionable to eat. One soon becomes accustomed to the odor, and there seems to be no bad taste. I have never noted any injurious effect from its use, either as food or as winter stores for the bees, and have not been able to determine whether the nectar itself has the objectionable odor or whether it is absorbed from the pollen. I have often observed, however, that other honey stored in the same place with the ampelopsis honey will soon become scented. When capped honey is left on the hive while this nectar is coming in, it seems almost as strongly scented as the ampelopsis honey itself.

The method I have practiced for several years seems to work very well with me; but probably under other conditions this plan would have to be modified. As soon as the first ampelopsis blossoms appear I remove all supers. If a colony is very full of bees I put on a second story, and into this I put any combs that are not ripe enough to extract, and fill out with empty combs. If there is a considerable flow of nectar coming in at this time, as soon as the brood-nest begins to get crowded in those hives that have no supers, I put on a second story, and move the full combs above, and put

empty combs below; but as a rule there is not much more nectar coming in than the bees need for food except in strong colonies. When the ampelopsis flow is over I remove all of this honey I can from the strong colonies, and store it above such colonies as are not strong enough to give any surplus from aster and goldenrod, and give to the strong colonies the partly filled sections that I had taken off earlier in the season. When it comes time to take off the supers I distribute the combs of ampelopsis honey among the hives as they are needed, feeding sugar syrup to those colonies that are still short of stores. This method works well in a small apiary.

I do not know whether it will do as well in a large one.

South Hadley, Mass.

THE HOMES OF BEEKEEPERS

BY WESLEY FOSTER

The home is the center of our national life. If we have not wholesome and happy homes it matters not how successful our business is—we are not getting the best out of life. We hear continually of the hardships of life on the farm and the barrenness of most of country living. The majority of specialist beekeepers live near or in towns, so they come in what we may call a semi-rural class. From my observation I believe that most beekeepers' families have fewer hardships and more pleasures than the majority of farmers' families. Rural conditions are improving, and well they may. The point is that beekeeping contributes to a wholesome, full home life. The remuneration for capital invested and time required is better than most callings coming within the agricultural class. I want to show you a few of the beekeepers' homes that have led me to make these observations. These are representative of western conditions.

The upper left-hand view is the home of Hon. O. C. Skinner, Montrose, Colorado. Mr. Skinner owns about 200 colonies of

Some homes of Colorado beemen. The middle view on the right shows R. W. Ensley's "iron-clad" mouse-proof bee-house.

FIG. 1.—Willows struggling to get a start.

bees, and manages a part of them himself. In a later article we will show a picture of one of his apiaries, located on a shed roof. The upper right-hand view shows the home of F. W. Brainard, Canon City; and the next one, the middle view on the left, the home of Geo. F. Lester, at Delta. The middle view on the right, while not the *home* of a beekeeper, is nevertheless the home of one of them for a part of the working hours, being the mouse-proof bee-house built by R. W. Ensley for one of his out-apiaries in Delta County. It is covered with sheet iron painted black. The two lower pictures show the homes of A. F. Foster, Boulder, and A. F. Stauffer, Delta. In connection with the latter, it is interesting to note that the bees paid for it in one year.

Boulder, Colorado.

THE WILLOW AS A POLLEN AND HONEY PLANT

BY J. L. BYER

Among the different honey sources of Ontario and other sections in the same latitude, probably none are more important than the willows, so familiar to nearly every one. True, they are not to be compared to the basswood, clover, and other sources of surplus honey, yet indirectly they play a very important part in beekeeping, as they are very necessary for the early pollen and honey they yield at a time when brood-rearing needs just such a stimulus. I believe it is estimated that there are about 30

varieties of willows native to Ontario; but personally I know only a very few by their right names, and generally the ones we are familiar with are called by local names whenever we refer to them. Mr. Doolittle, if I am correct, claims that the pussy willows yield no nectar; but I am convinced that in this locality they do yield some as well as an abundance of early pollen. In this connection it is well to recall the fact that Mr. Doolittle claims that the basswood yields no pollen in his section, while here, more than once, I have seen the bees getting large quantities of greenish-colored pollen from this tree, all of which goes to show that either localities differ or that observations have been made at a time when atmospheric conditions were not favorable for the secretion of honey in the case of the pussy willow, or for pollen in the basswood.

The large varieties of the willows, such as are commonly seen around mill-dams and creeks, are great yielders of nectar, and I have often seen the bright drops glistening in the early morning of a warm day in late April or early May, according to whether we have an early or late spring. With good weather for a few days, the strong colonies will literally flood the brood-nests with nectar, and brood-rearing receives a tremendous impetus such as no artificial feeding will bring about. Once I knew of a large quantity of surplus taken from an apiary near us, but that was an exceptional season, and the bees were abnormally strong. It is not likely to happen again in twenty years.

The willows in general are very easy to propagate, a small limb stuck in the ground

in early spring nearly always growing, especially if the soil is of a moist nature. Along the banks of streams it delights to grow; and it is wonderful to see the buffeting it will stand from ice, floods, etc. Once getting a foothold it grows rapidly, and defies almost any thing that would easily kill any other tree. Within a few yards of our home a stream runs through a strip of bottom land about a quarter of a mile wide, and for a number of years these "flats" near us were pastured closely. Every thing had been cleared off in the shape of timber, and naturally the cattle kept all willows that might get a start after the spring floods trimmed off at sight. During the past four or five years this land has been devoted to growing hay, and the willows that have started along the sides of the stream are forging ahead, and are in many cases out of all danger of the cattle. The farmers do not object to them, as they act as a soil-binder and prevent the banks washing away each spring. Great floods rush through this flat land every spring, and floes of ice strip off much of the bark of the young trees, but still they grow.

Fig. 1 shows some of the willows referred to, and will give an idea of the harsh usage they have to endure each spring in their struggle for existence. The "flats" had been covered with a raging torrent the day before the picture was taken, and the following night a sharp frost came and the stream lowered, leaving an ice jam about a quarter

of a mile long. The willows can be seen at the left of the picture, with the ice piled around them. In the distance, and to the left, can be seen our house, while to the right, still further away, will be noticed the church that our family attends.

The other picture shows the stream just a few yards west of the house, and a neighbor's bridge for crossing to the road. The large willows shown there were planted to help hold the abutments of the bridge from washing away in the spring freshets; and it is not so very many years since we stuck in mere branches, and now they are great trees that serve the purpose originally intended when they were first planted, and are, besides, a source of delight each year to the beekeeper and his family who live so near them. If any one has waste land it certainly pays to plant the larger varieties of willows for bee forage, as they grow so very quickly and yield nectar every year provided the weather is suitable for the bees to visit the trees at the blooming period. One man I know, who is not a beekeeper, plants willows along a narrow stream that runs through his property, to avoid the land washing away, and in addition to filling that purpose, admirably he systematically uses this ground for producing fuel for his use in summer months, cutting down the trees as they assume large proportions, but all the time putting in fresh slips to keep up the supply.

Mt. Joy, Ont., Can.

FIG. 2.—Willows planted for the purpose of preventing bridge abutments from being washed away.

SOUTHERN BEEKEEPING PROBLEMS UNLIKE THOSE OF THE NORTH AND WEST

BY L. W. CROVATT

When the ordinary every-day beekeeper of southeast Georgia reads in the bee journals of the perplexing problems encountered by brethren in other parts of this great country centering about the wintering proposition he should feel thankful that this is not one of the troubles which confront him.

Ordinarily speaking, the terrific rigors of the snows and freezing temperatures may be said not to exist in "this neck of the woods." True, we have at times weather which is unusually cold; but there is never in the region of the coast, in "the flat lands," such low temperatures that strong colonies would freeze, even with full-depth entrances, such as are used in summer. Hence the bees are wintered on the summer stands.

In other words the original place where the colony is put is regarded as a definite fixture for all time, providing, of course, that no move otherwise be deemed necessary. Hence the average apiarist is enabled to sit calmly by the fire in the winter and reflect upon the troubles experienced in the West and North, where the task of taking the bees to the cellar and again moving them to their stands when the "mystic touch of nature" will have caused the balmy air to be again suited to the needs of the busy workers.

Down in Georgia, on the banks of the Savannah River, some three hundred miles from Atlanta, the capital, the average beekeeper can also smile at the thought of the problem of "building up" for the spring flow. Further upstate there are splendid spring flows, principally from the titi and

gallberry, which afford a water-white honey of splendid color and body and of excellent quality. But down here in Chatham County the spring flow may be said to be a negligible quality, for there is little to be had of the superfine blend of amber honey from the myriads of wild flowers.

It is unnecessary, therefore, to worry particularly about the "building-up" process. True, it is recognized that strong colonies are desirable under any and all conditions; and we, for this reason, keep an eye open for developments, giving "the helping hand of man" to nature if necessary. As a usual thing, however, mother Nature is fully equal to the occasion in this locality.

"Why, far-southern Georgia must be the ideal spot," I hear some one say in fancy. But pause, brother; for, while we have ideal climatic conditions, we get practically no spring flow in this section of Chatham County, and are, therefore, absolutely dependent upon fall flowers, principally goldenrod and swamp myrtle for our surplus, and fall weather is, to say the least, rather uncertain.

This spring I have on the hives at this time (my home apiary of fifty colonies) about eighteen hundred or two thousand pounds of a very dark inferior honey secured from a source unknown as yet, which will probably not net three cents a pound; but this is the exception to the rule as before noted. I get \$2.00 per gallon for fall honey.

Queens in strong colonies as a rule begin depositing eggs about the middle of January. This depends largely upon the honey left over from wintering, as it is unusual to disturb the brood-nest. By early March, peach, pear, and plum trees begin to bloom, and this gives a great stimulus to brood-rearing.

A corner in one of Louis H. Scholl's apiaries of divisible brood-chamber hives,
See Beekeeping in the Southwest.

By April the colonies begin to swarm if let alone; but prevention of natural swarming is greatly desired. I have adopted the method of seeking the queen and removing her on one frame of brood, taking out the brood-nest and placing on the bottom-board the super or full-depth extracting story (which is always empty in early spring). The brood-nest with the other seven frames is placed above the honey-board. If no increase is wanted I go back in eight or ten days and destroy the queen-cells; but when increase is needed I merely leave an opening under one end of the cover. In time I have a fine Italian queen at work, which was raised by the bees. She sees to it that there be no rivalry, by destroying all other cells.

By August our colonies are of rousing proportions with thousands of workers tearing in and out of the entrances as if "possessed," seeking nectar and pollen.

Toward the middle of August the golden-rod begins to bloom. In September the swamp myrtle is showing its pretty minute white blossoms on all sides, and in October the extractor is brought into play and the surplus made ready for the market. This honey granulates in from three to five months.

In handling surplus honey I have always made it a practice to deal directly with the consumer. I guarantee every drop of the honey sold, and frequently have customers who take from two to three gallons at a time and call for more later. Of recent years little comb honey has been produced in my apiary because of the swarming propensities thereby developed; but another year I shall be compelled to return in a measure to such production because of insistent demand for fancy comb products.

Savannah, Ga.

FEEDING BACK EXTRACTED HONEY FOR FINISHING SECTIONS

The Requirements for Success, such as the Question of Bees and Queen, Weather, Feeders, etc.

BY E. S. MILES

Now and then there is a beekeeper who reports success in feeding back; but perhaps the majority do not find that the plan works well at first. I myself was among the latter class; but having studied the theory of it thoroughly I was able to see some of the causes of failure, and after several trials was able to eliminate most of them, so that now I consider the finishing of some of the section honey by feeding back a part of the regular program each summer.

As there is a scarcity of section honey now, as compared with the supply of ex-

One of Scholl's shallow-story divisible-brood-chamber hives. A veritable stack of bulk comb honey.—See *Beekeeping in the Southwest*.

tracted, it would seem that every thing tending toward helping the producer of comb honey would be in order. As to whether it pays to feed back, I can not say positively. I think it has paid me, yet it might not pay another. It would depend upon how he is managing his bees, number of stands, how much his help costs, and what his time is worth in other work.

As to feeding for the purpose of getting sections finished, the following points in the order named as to importance must be considered.

1. Character of bees and condition of colony to be used.
2. Kind of weather to be expected for the purpose.
3. Arrangement of sections in supers; supers on hives; kind and arrangement of feeders.
4. Preparation of feed and method of feeding.

The right kind of bees is absolutely necessary as a foundation to success. As nearly as I can tell, a colony that does first-class work in sections in a honey flow will usually though not always be all right for this. I always try those that have been the best

The hot-weather costume in Uganda, Africa.—See A. I. Root's department

and quickest at finishing their sections; and if they prove good for feeding back I use the same colony each year until the queen begins to fail. I do not say black bees are the best, nor hybrids, although more suitable colonies may be found in a given number of these; neither do I say a good prolific queen will insure that colony being a good one for this purpose. My experience is that any colony that does good work in sections has a queen that keeps at least a reasonably good-sized brood. But on the other hand I have known some very prolific queens whose bees did not seal and finish their combs as quickly as others. So in working the colonies for section honey during the flow I watch for quick sealers.

It has been my experience too (but this may not be the same in all places) that the colonies fed are quite apt to swarm. As this should be avoided, I make it a point to select among the quick sealers those that have stood the greatest pressure without swarming. Luckily these two traits often seem to go together—those that are slow to swarm usually being good storsers and sealers. It is hardly necessary to add that, every thing else being right, the stronger these colonies are, the better. One does not want to use any more colonies than will finish the number of sections he expects to have, as each colony uses considerable honey before doing the best work in the sections; and the more sections one colony finishes, the greater the chance for profit.

This depends largely on the weather and length of time one has to continue the work, and his success in choosing the right kind of colonies for the work. My experience for

western Iowa is that the white-honey flow from clover and basswood usually stops about the middle of July, and heartsease begins to yield a little from the 10th to the 15th of August, so that I can count on about three weeks between flows in which to feed. I am doubtful whether it pays to feed during a flow. Mr. Alexander, whose opinion we all respect, said it did; but the one time I tried it, those colonies did not do as much in the supers as the ones not fed, and 75 per cent swarmed within a week or ten days after the feeding was started. One swallow, however, does not make a summer, we are told; so this experience might not always be repeated everywhere. In the two or three weeks' time between clover and heartsease I have usually gotten from 15 to 25 supers finished per colony. The right kind of weather is also necessary. But, fortunately, here in Iowa we usually have good weather for feeding at just the time needed. It is hardly necessary to say that it requires good hot weather with warm nights. The arrangement of supers and feeders is of importance, as the better these are, the more chance for success. I was never able to make much headway at feeding back until I began using the Alexander feeder. There may be others as good for this purpose, or even better; but I know the Alexander feeder is all right. I have some made of 2 x 6 stuff, and long enough for ten-frame hives, which I use on eight-frame hives, and I prefer two feeders on each hive. This gives capacity for a large feed, so that, if one does not feel able to take the time to feed any during the day, a feed each evening is equal to a good fair flow. When placing

the feeder, set your colony to one side, lay down one or two solid pieces of plank three or four feet long; put on the feeders and bottom-board where the hive stood; then replace the hive of bees, first driving them from the bottom of frames by smoking them so as not to mash any bees when setting on the end cleat of the bottom-board and partitions in feeders. The hive should also be blocked up $\frac{7}{8}$ inch at the front end for ventilation. If this blocking up leaves a crack between the first feeder and the hive, push a couple of small strips under it so that all will be tight around the feeders.

One must be careful to see that robbing does not get started; for while these strong colonies may not be robbed out, yet a big fight, and bad bees to handle, may result, as well as having the work hindered.

After the feeders are adjusted properly, put on two or three supers of sections, and in arranging the sections to go back put those which are the nearest finished on the outside of the supers. If there are as many as eight sections for each super all sealed on one side, put the sealed side to the outside of the outer row in each super. It is doubtful whether it pays to feed for any less than half built out. But those needing the most work must always go into the middle rows. The nicest work is on those just about built out but not sealed over. For securing the best results, those partly sealed should be uncapped. I think it is preferable to take off all sections a little sooner than usual where one feeds back, as it not only keeps the combs and sections freer from travel-stain and propolis, but it is not so necessary to uncap the sealed portion as it is after the flow has slackened when some combs are sealed light or thin. If feeding, or another flow starts, the parts unsealed will be "bulged," for the bees will build these unsealed parts out to the proper distance from the separators, even if it is only two or three rows of cells at the bottom or sides.

If, however, they are taken off as soon as the height of the flow is over, in most cases only the part built out will be sealed, so that, when the work is taken up again, it is more as it would have been if the flow had continued until the combs were finished. I think this is worth considering; for not only is it a puttering and difficult job to uncup sections, but these uncapped combs drip, and tempt robbers, and make more work for the bees, for a good part of this uncapped honey will be taken out of the combs as soon as the bees get a chance.

I do not like the common standard super for getting honey finished. I prefer a super $\frac{3}{4}$ inch wider than the standard width, so as

to allow a slatted separator to be tacked to the sides of the super, using $\frac{1}{2}$ or $\frac{5}{8}$ inch sticks behind it, thus giving a clustering space *outside* the outer row of sections in the super. These sticks are put one at one end of each section, thus using five sticks to each super. Then have the follower board perforated with $\frac{3}{8}$ -inch holes, or slots, so the bees in clustering behind the follower will also have access to the outside of the combs on that side. Such an arrangement is a great help in getting the outside rows built out, either during a flow or when feeding. There is no trouble in using such a super on a regular hive, as it projects only $\frac{3}{8}$ inch on each side; and any cover, unless, perhaps, a telescope, will cover it just as well.

The feed for finishing white honey must be white honey, of course; but it need not be ripe; in fact, it must be green, or else thinned to the consistence of green honey, and it should be fed as warm as can be used without killing bees.

When the flow is drawing to a close, if a colony has the supers about finished, instead of putting on another section super on top, as is usually recommended, put a shallow extracting-super on the brood-chamber and put the sections on top of an escape-board, and get them off; mass the unfinished into supers as described above, on quick sealers, and extract these shallow supers as fast as needed to feed the quick sealers. To one who has not tried it, it may be a surprise how much some colonies will put into a set of built combs after section work has about come to a standstill. I would recommend that the first few feeds be given at dusk, so as to avoid any danger of robbing; but after that, the bees become somewhat accustomed to it, and the feeder can be filled as fast as emptied all day. Use a good smoke in feeding, keep the bees out of the way so the feeders can be rapidly filled, and keep any robbers or stray bees away from the feeders while uncovered. The hives should stand level sidewise, so that the feeders will hold their full capacity; and they should not slope much toward the entrance, for the same reason.

As soon as wax secretion is well under way, as can be told by seeing that the lighter combs in the center are being built out, raise up the supers and put on two more. I always try to have five or six supers on after wax secretion is well under way, always having the nearest finished ones at the top, and one or two with plenty of storage room in them next to the brood-chamber.

If I have about all the supers necessary on, and still no super is all finished, I take

off one or two of those nearest finished, and either raise the others and put on more, or, in closing up, mass the unfinished from these on one or more of the best of the colonies fed; and as I finish up I drop the number of colonies used accordingly. I also taper off the feeding when there are no more partly built ones to put on. In putting back the last few supers of these fed sections that are nearly done, only a little feed comparatively is necessary in order to get them capped.

The last super to the hive will be likely to be a little travel-stained, as it must be finished next to the brood-nest. The others having been sealed one or more supers up from the brood-combs, and while new wax is plentiful, are very good, although not quite equal to those built and finished in a good steady flow. But I think that often what would otherwise have been No. 2 to culls, can, by this management, be made into No. 1. I find less honey in the brood-chamber after two or three weeks' feeding than one would expect where there is a good queen. At first, as in the beginning of a heavy natural flow, the brood-nest is chock full; but after the bees begin storing above, they seem to get their "second wind." The queen gets down to business, and the loose honey goes above.

I frequently find colonies with hardly winter stores in the brood-combs after two or three weeks of heavy feeding. But these colonies will be "powerful" strong, and must have attention so as not to swarm after the super room is taken away, especially if there is a little natural "picking."

Dunlap, Iowa.

THE VARIOUS PHASES OF THE SWARMING PROBLEM CONSIDERED

BY DR. C. C. MILLER

Continued from page 405

bees are thinking about swarming, make search for queen-cells in some of the strongest colonies. If no cells are found in these strongest, no need to go any further. If any are found, then it may be best to go through the whole apiary, destroying all eggs and larvæ found in queen-cells. Ten days later make the rounds again. Destroy, as before, all eggs and *young* larvæ in queen-cells. But if a colony is found with sealed cells, or cells containing larvæ well advanced, then the colony must be treated. If the queen be a good one that you wish to retain, take her with two frames of brood and bees, and with these form a nucleus, and kill all cells on the frames left. About ten days later, kill all cells again, and return the

queen with her two frames and bees. Leave a vacancy at one side of the hive while those two frames are absent—little danger that those queenless bees will build comb there. That colony may not make any further start toward swarming again, but it may; so you must examine every ten days, and treat it again if advanced larvæ are found in cells. I don't think I ever knew a colony to need more than the second treatment.

Suppose, however, you come to a colony needing treatment whose queen you do not care to continue. Remove the queen, kill all cells, and at the end of ten days again kill all cells and introduce a young laying queen. (Having young laying queens ready is an important part of the game.) If your young queen is in a nucleus with full-sized frames, a nice way to introduce her is to take her with two frames—more frames if she has them—as also the adhering bees, and put them in the queenless colony. That colony you may now call a "passer," for you will "pass" it at each examination without further attention for the season.

Some colonies will never get any further than to have eggs or small larvæ throughout the season, and, of course, they will need no treatment. Some may be found, especially if you have good stock, that will never have even an egg in a queen-cell throughout the season. These will be the ones likely to have record crops, and among these you should find your stock to breed from.

Marengo, Ill.

[In his article Dr. Miller refers to the shake-swarm method, assuming that our readers are familiar with it. As some of our newer readers and some beginners may not know just what it is, we here give it as it appears in the latest edition of the A B C and X Y Z of Bee Culture.

After the honey-flow has begun, and perhaps three or four days (not earlier) before the colony is expected to cast a swarm, the hive is moved to one side of the stand, and an empty one, just like it, is put in its place.* In this hive are placed frames having foundation starters or frames with full sheets—preferably the latter. But if neither is available, empty combs may be used. The bees of the parent colony are then shaken or brushed in front of the entrance of the *new* hive on the *old* stand. Some go so far as to brush *all* the bees out of the old hive; and this can be done if the weather is hot and the nights warm; for young hatching brood will soon be out to take care of the young brood. The supers from the parent hive are next put on the new one. The parent colony is then moved to a new location or left by the side of the new hive with its entrance

* Reports show that if the colony is shaken or brushed, from a week to ten days before a swarm would otherwise issue, no good will be accomplished, and that the bees will be likely to swarm. The shaking should not take place *before the bees feel and show the desire to swarm.*

facing in the same direction. In either case the entrance should be contracted.

If work is already partly begun in the super, the bees will continue work, and rush the honey above. In some cases it may be advisable to use perforated zinc between the super and brood-nest to keep the queen below.

It is encouraging to note that Dr. Miller still thinks favorably of the shake-swarm plan. Some years ago it was believed that this method was going to solve this much-mooted problem more fully, perhaps, than any thing else that has been proposed; but of late years we have not heard so much about it—not because we supposed it is not in use, but rather because it was so much discussed years ago that many users of the method think it unnecessary to keep harping about it. But it occurred to us that the shake-swarm method might be profitably discussed again—that is, as to whether it has been a success as it originally promised.

So far as we can see, Dr. Miller is entirely orthodox—that is, he has set forth the general principles governing the laws of swarming, and the beginner will do well to read very carefully what he has to say.—Ed.]

SOME SEASONABLE DONT'S TO THE OWNERS OF AUTO TRUCKS

BY ROBERT M'LEAN

Having noticed Mr. D. L. Woodward's article on auto truck for migratory beekeeping, Apr. 1, p. 213, I will give a few suggestions which may be of use to him.

Mr. Woodward speaks of his first season's experience being pleasant but quite expensive. Well, that is the case with most people in their first season's use, but with a large number the pleasant part is omitted. From the appearance of his car and the horsepower he must terribly overload it or the engine is not in the proper condition if he uses a gallon of gasoline for six miles. Usually with a car of 40 or 45 H. P., double the mileage he obtains from a gallon of gasoline is not considered any thing unusual. Although the care and condition of the engine goes a long way toward obtaining the proper mileage, there are numerous causes which would tend toward excessive consumption of fuel.

First, if the carburetor is not properly adjusted it will cause the engine to burn gasoline without getting good results, and would cause an excessive deposit of carbon in the cylinder.

Leaky piston rings or valves cause loss of compression, likewise a loss of gasoline vapor. The remedy is to use new piston rings or grinding in the valves.

If the spark is not kept well advanced while running, the consumption of fuel will be greater than when operating under an advanced spark. On some cars the throttle can be opened so the car goes about 15 miles per hour on retarded spark, and by advancing the spark the speed can be doubled without any increase in fuel consumption.

As a general rule, converted touring cars are not very successful when operated as trucks, because the owner usually thinks that a touring car having from 30 to 60 H. P. can carry a load on its chassis equal to a truck of the same power. Overloading is death to pneumatic tires—in fact, any tire, even a solid one, will not give satisfactory service when overloaded, and the same applies to the car as well as the tires.

From all appearances Mr. Woodward has an extremely heavy body on his car, which, when loaded, will account for some of his cost of operating and upkeep. A commercial body placed on a car should not be any heavier than the touring body it replaced, and better if not as heavy, if it can be built substantially enough without excessive weight.

It is not considered good practice to have the body overhang at the rear more than one-third of the total length of body, as it puts too great a weight on the rear wheels, resulting in excessive tire wear, which every one owning an automobile knows is expensive.

I think that, if a person secures a sturdy car of some good reliable make, and has convertible bodies, one for pleasure and another for commercial work, with a reasonable amount of care they can be operated more economically than a team of horses, considering the amount of work done and the larger territory it enables one to cover.

There is undoubtedly a great future for the light truck in the beekeepers' line of work in nearly all parts of the country. I have had considerable experience in the manufacture and repair of cars.

South Haven, Mich.

SPRING MANAGEMENT

Caution Regarding Early Manipulation

BY CHAS. H. CARGO

When I began beekeeping it was with a clear board—no designs of the art, good, bad, nor indifferent, clouded my views. I had no knowledge of either the box hive, Langstroth hive, Danzenbaker hive, nor any other hive. Viewing my assets in this light I discovered that this negative fact was of real value, as I was not called upon to part

with preconceived notions, and could listen to the pro and con of argument.

The best results in a practical way are obtained from methods which have been put into practice by the individual beekeeper himself, and with which he has gained experience, spelled with a rather large *ex* too.

The first thought in returning springtime is, "How are the bees?" Well, we must see. No, don't. In taking this first walk among the bees we will imagine a large sign ever hanging in front of us on which we see the words, "Bee Careful." The first visit may well be confined to changing bottoms for clean ones, and leveling up all the hives to a true level sidewise, and an examination of a few hives throughout the apiary only. An axiom comes in to explain this, and it is handy all the year—"Never disturb bees without brood." Bees without brood sometimes leave their hive; and in one case bees in an upper brood-chamber left their hive while it was set aside a few moments, and attempted to return to their regular entrance below, and were killed (some reason to be a wee bit careful). I believe the bees need to be stirred up to their work, but it is to be done gently. One season I found a hive being robbed. The robbers were trapped, and I thought it was just the thing; but, alas! I found later I had ruined another colony as well as the one robbed. Be sure you know the whole trick before going too far.

In a day or two we go to the yard again, and with more confidence if fair weather has intervened. Hives are now opened and brood-nests hastily examined and contracted wherever necessary, and the hives closed. The condition in which the bees are found is left penciled on the side of the hive. The season's work now swings out in full view before us, and the notes left on the hive become our chart to study and ponder over. What method shall be pursued, and what harvest is to be sought? Market conditions and flora both are to be considered. Early queens are to be raised or bought, and the extent of increase fixed.

Swarming is to be provided against by proper management, and bees must be watched closely to prevent heavy injury from orchard spraying. The National Beekeepers' Association should test out a case of intentional poisoning under our present laws against some blossom-sprayer, so as to define clearly the right to put out poison on blossoms, whether bees are known to be kept within a reasonable distance or not. No new law is needed to cover such cases, but a precedent ought to be established. I doubt if it is necessary even to prove that

any bees were killed. Proof of the spraying and its poison on the blossoms is usually sufficient. That is, prove that honeybees visit apple-blossoms, and that such blossoms were intentionally poisoned. How would a very small entrance do for the week of apple-spraying, to save brood?

Beginners should not treat their bees as so many treat their horses—turning them into a field but never looking over the fence to see if any grass is there. Examine your flora. Know it. Fill in the gaps as best you can. Even a very small flow is then of increased value. Raise any thing, or see that some one else raises it near you. Alsike clover, sweet clover, buckwheat, are standard. A small patch of sweet clover is of great worth to a whole apiary for a fall flow.

Bladen, Ohio.

ANOTHER UNSATISFACTORY EXPERIENCE AS A HELPER IN AN APIARY

BY B. H. VAN TRESS

On p. 58, Jan. 15, the editor thinks "Subscriber" was a little hard on the California beekeepers. I know that there are many perfect gentlemen among the beemen of California; but I also know that there are others just the reverse. I had an experience very much like the one described, and, in addition, I had a sick spell of two weeks caused by eating food not fit for human consumption. My employer then refused to pay me full wages for the little time I was able to work; and as I was among strangers I was obliged to take what he offered or nothing.

My advice to those looking for work of this kind is to make diligent inquiry first; and if the one looking for help does not answer fully it is better not to make the experiment at all. In the future I shall stipulate \$5.00 more, and traveling expenses one way, if the bargain is not lived up to strictly.

Greenleaf, Idaho.

[Undoubtedly there are unscrupulous beekeepers who will take advantage in every way of a helper; but there are plenty of good men who are anxious to get good help, and are willing to pay reasonably for it. It is a great education to a young man desiring to learn the bee business to work a season with different producers.

As a matter of business we advise having a full contract drawn up in writing, which should be signed by both parties. A lot of trouble? Yes, to be sure; but such a precaution might save ten times more trouble later on.

The following from J. G. Gilstrap shows the class of helpers that many ranchers have to depend upon in an emergency, and this condition, of course, influences the wage paid for help in general.—Ed.]

AN ANSWER TO "SUBSCRIBER," PAGE 58

BY J. G. GILSTRAP

We are glad that GLEANINGS conducts an "experience" meeting. "Subscriber" gives his experience in California. I have had nearly thirty-seven years "experience" in California, and about twenty-five of that has been devoted to apiculture. There is nothing strange nor startling about Subscriber's experience when one knows the conditions here. The climate here, warmer than exists in most of the States, induces thousands of the hobo class to come. They are usually found counting ties along the railroads or else in squads or bunches of half a dozen or a dozen at the hobo camps along the railroads cooking their mulligan stew in an old can. Not infrequently these pestiferous fellows have in their stew a chicken from the much-hated rancher's hen-house, together with potatoes and other edibles gathered at random from the fields, and that, with a chance loaf of bread begged from the good lady of the near-by farm, gives a feast for the "squad."

These hoboes may justly be classed into two lots—professionals and blanket men. The professionals have reduced the system to such a science that they rarely "sleep out." As a rule they are the smooth fellows who try to keep up a better appearance, and get a bed furnished if they can, in some bunk house about the large farms where many men are employed. They do not carry a bed except in the winter season, and sometimes not then. These professionals are divided into two classes—those who work part of the time, and those who never work.

Well, the blanket men are usually a better set to have around than the professionals, but the same danger exists in contact with either. I speak from sad experience. My friends, too, have often had the experience of having been stocked up with vermin (we always just call them lice or graybacks), from the hoboes. It has come to pass that here in California not one of them will be hired by any self-respecting apiarist or farmer except for a short time when an extreme emergency demands help.

The class of apiarists that Subscriber tells about working for, however, has a hard time generally in keeping or securing decent help, so they have to take what comes, and

too often it is dear help then even though the pay be only \$30 a month. I hope to see the day when the State law will regulate the premises of the beeman as thoroughly as does the present State dairy law the premises of the dairyman. Make them clean up, if they have not enough pride and self-respect to clean up themselves.

I have kept bees in several counties in this State, and have worked for a number of apiarists; and a cleaner, more refined lot of men I never met as a class than the California apiarists. Most of them are Christian men. Many apiarists pay \$1.50 per day and board when they hire help.

Ceres, Cal.

THE TREATMENT OF EMPLOYEES ON A BEE-RANCH.

I notice a communication, "The Other Side," Jan. 15, page 58, under the above caption. Will you please allow me to refute, at least in part, a portion of the statements made, and to give some facts on the other side? My brother and I run 800 colonies for The J. W. George Bee Co., and receive as wages \$65 a month each through the season (eight to ten months). We have access to a grocery store, and have every thing we wish to live on—good camps and rigs are furnished us to go to our outyards. Mr. George takes us to Sunday-school, and Mrs. George comes out and cleans up for us sometimes, and cooks us a nice dinner. I do not think good and worthy labor ever goes begging in California.

Imperial, Cal. THOMAS Y. ATCHLEY.

A Paper-hanger's Tools for the Apiary; Fountain Pen Filler for a Foundation Fastener

Being a paper-hanger by trade I have been using some of my paper-hanging tools to good advantage in my apiary. Among them is the clipped-point wall-scraper, three inches wide, which I use in scraping hives, bottom-boards, for prying, etc., the point being clipped in such a way as to reach in corners better than the regular scraper or putty-knife.

I also use my 16-inch smoothing-brush in brushing the bees off the combs, which takes them off at one sweep.

Another little tool I am using to advantage is a fountain-pen filler, or eye-dropper, as a wax tube. I have a can about two or three inches deep, the top being narrow enough to prevent the tube, when standing upright in the wax, from falling over. This can, about two-thirds full of wax, is placed over a lamp which can be kept at the proper temperature for flowing freely by regulating the blaze. By using a small tube of this kind I can do very neat work in fastening foundation.

I have read that some beekeepers are having trouble with the spur wire-imbedder weakening the foundation so that it breaks at the wire under the weight of the bees. I have overcome this trouble with my little wax tube, with which I can run so small a stream of wax down the crease over the wire, strengthening the foundation very materially.

Bedford, Iowa, May 17.

Heads of Grain from Different Fields

What are the Difficulties in Shipping Bees without Combs?

Dr. C. C. Miller:—I want to buy a lot of queens with 1 to 3 lbs. of bees without combs of brood or frames, and put them in ten-frame hives with full sheets of foundation. Kindly advise me what I am to guard against in order to prevent its being a failure, for, buying bees on combs, I am liable to get foul brood. The A. I. Root Co. have shipped bees by the pound this past summer to test it, and have been successful. I will not have any drawn combs or brood—only foundation in full sheets in Hoffman frames.

Canastota, N. Y., Jan. 6.

WM. P. FRITZ.

[Dr. Miller replies:]

I had three separate shipments of this kind, and had difficulty in only one respect; so I know of only one thing to put you on your guard against. Otherwise a cage of bees shipped in this way may be treated exactly as a swarm. My one trouble was to get them out of the cage. The first lot that came was a beautiful sight to me, they looked so nice and comfortable. They had a pleasant look, too—a smiling look, you might say, as if saying to me, "Just see what a nice place we have here, snug as a bug in a rug; nothing better could be desired." "Yes," I replied, "that's a nice cage, but I can give you something better. I'm an old beekeeper, and I know all about bees. I'll soon have you out of that."

I put into an empty hive a brood-comb containing some honey, set the cage in the hive beside it with the opening of the cage directly facing the comb, covered up the hive and went away, leaving the bees to come out and cluster on the comb at their leisure. When I went back later in the day to take out the empty cage, there was no empty cage there. It was just as full of bees as ever. I began to think that may be I didn't know all about bees after all.

I'll tell you later how I managed to get them out; but first I want to tell you about the right way, as learned from Medina, to which place I applied for light as to the right way. It seems that they too had suffered under the delusion that I knew all about bees for they had sent no instructions as to getting out those bees. Promptly came back the response, "Shake them out, just as you would shake out any swarm!" Sure enough! how simple! Why hadn't I thought of that?

So I was ready when the next lot came. I opened the hole in the cage, and gave it a gentle shake. I didn't want to be too rough with those bees. But the shake was too gentle. The bees stayed right where they were. Then I shook harder, and a few bees were thrown out. To all further shaking the bees replied, "We're quite comfortable where we are, thank you," and stayed right where they were.

Then I set the cage on the top-bars, the opening of the cage at the bottom, and covered over the rest of the hive with little boards. I then blew a stream of smoke horizontally at the top of the cage, kept the smoke going steadily, and lowered it as the bees went down until the cage was empty.

You intend to put your bees upon foundation; but I think you will do well to borrow a frame of brood for the bees to go down upon, and then you can take away the brood as soon as the bees are out of the cage.

Marengo, Ill.

C. C. MILLER.

[Bees will shake out of a small cage because the filling-hole is relatively large to the size of the cage; but in the larger sizes this is not always practicable. A better way is to take off the wire cloth on one side, shake, and then lay that side of the cage over the set of combs or frames on which they are to be hived. If there is a frame of unsealed brood and honey it will be better. A frame of eggs and young

brood will "draw" as nothing else will. In a few hours all the bees ought to be out of the cage, and on the brood.—Ed.]

Golden Bees Hardy, Gentle, and Good Honey-Gatherers

After reading Mr. Snyder's article, Jan. 15, page 53, I felt like throwing my hat into the air, it did me so much good. I have noticed that our editor for some time has given the Goldenes the "black eye." I have felt like speaking out for Goldenes, but have been afraid to, for we little fellows can't make noise enough for any one to hear us, especially when "one of the largest honey-producers, and a queen-breeder as well," has the floor.

A few years ago I bought some red-clover queens, and then the season following a Golden queen. I kept them in the same yard and watched them carefully. I found the Goldenes as hardy, gentler, and better honey-gatherers than the three-banders. I remember well two three-banded queens and their bees. One queen and her bees were light in color for three-banders, and her bees were more gentle than the darker ones.

The darker bees swarmed out one day; and when I undertook to hive them they would sting. 'So I killed all my three-banded queens and used the Golden queen for a breeder. The Goldenes worked red clover just as well as the three-banders. After this I saw the queen-breeder that I bought my Golden queen from, and he told me that he had quit breeding the three-banders because he liked the Goldenes much better, and that they were better honey-gatherers, and more gentle.

By the way, I have two Swarthmore pedigreed Golden queens, and I intend to test them out; but I am afraid they will not have bees gentle enough for my little children to "grab out honey by handfuls." But one thing is sure, if they prove to be as cross as the three-banders I just told you about, I will pinch their heads.

Of the three leading types of beef cattle, two are bred for color as well as beef. The Aberdeen-Angus are black, the Herefords must have white faces, the Durham or shorthorns may be "off" in color. But what of these cattle at the international stock show, Chicago? The types that carried off most of the ribbons were bred for color as well as beef. Why not honey and color in bees as well as beef and color in cattle?

Naylor, Mo., Jan. 29.

R. O. MARLIN.

[GLEANINGS certainly does not wish to give any strain of bees the "black eye" if such is not warranted. We merely maintain, as we have explained before, that, while many individual colonies of Goldenes are hardy and gentle, the majority of them are below the average of the leather-colored Italians in these two points. Note the opinion expressed by G. A. Barbisch which follows; also that reported by E. G. Ward on another page.—Ed.]

Golden Bees Do Not Stand Cold Winters

I have been experimenting with golden Italians for the last five or six years, sending for queens from queen-breeders all over the country; but I am sorry to write that I have been disappointed with them in every instance. They can not stand the severe cold and backward springs we have up here in the North. If they do not die altogether they dwindle so that they are no good whatever in storing surplus. They are very backward in breeding up early in spring, and are much slower than the leather-colored Italians. They swarm about as much as any bees I ever had, and they are just as cross and irritable as any Italians I ever had in my yard. These Goldenes may be all right in the South; but

one thing is certain—they can not stand the cold and rigid weather of the North.

They are beautiful bees to look at, but that's about all there is in their favor. In nearly twenty years of beekeeping experience, and after trying nearly every strain of bees advertised I have found the pure leather-colored Italians ahead of all the rest—at least they are the best bees for this locality. The past season, when so many bees died, the Goldenes were the first to succumb; and while many of my Italians pulled through, not one of the Golden colonies did. In the future I shall have none other than the leather-colored.

La Crescent, Minn., Jan. 21. G. A. BARBISCH.

Hoffman Frames with Square End-bars; Some Relics of the Past

I like the Hoffman frames in every way except that mean V shoulder. It slips over the shoulder of the opposite square one. Why not make all the shank shoulders square?

The Langstroth hive is hard to beat, and the Italian bee has come to stay; but what about the hive that was going to do away with swarming? I think it was called the "reversible" hive. It was claimed to stimulate brood-rearing by turning it upside down; and if at any time you suspected a swarm was about to issue, all you had to do to forestall the swarm was to give it another turn upside down. I wish I had such a hive. I have been looking for it ever since.

Have queens mated in confinement been a success?

What was the outcome of the lamp nursery?

Slate River, Ont., Dec. 10. J. M. MUNRO.

[There has been some objection to the V edge of the end-bars of the Hoffman frame. The purpose of this was to cut the propolis, as the frames are crowded together. Some beekeepers wish the end-bar square on both sides, and we have made Hoffman frames in this way, although by far the greater majority prefer the V edge, for the reason stated. There is no question but that in localities where propolis is very bad the square edge end-bars are much harder to keep accurately spaced than the V edge.

Reversible hives and reversible frames have come and gone, and probably more will come and go in the future. There are some advantages to be gained by reversing the frames or reversing the whole brood-chamber; but in the end the extra expense of the equipment and of the labor required probably offset these advantages.

So far as we know, there are no experiments being conducted at the present time along the line of getting queens mated in confinement. The experiments that seem the nearest to success were those in which mammoth tents of wire cloth were used, but there were so many failures that the few successes did not pay for the expense of the undertaking.

The lamp queen nursery or incubator is likewise a thing of the past. There were possibilities, but it was found that bees can attend to work of this kind better than man aided by artificial heat, etc.—ED.]

Carniolans Not Immune to Disease, but Fully as Resistant to it as Italians

Nov. 15, page 744, H. Perkins, of Artesia, Cal., mentions the claim made by Eugene Baker, of Los Angeles, that Carniolans are more resistant to European foul brood than Italians, and asks that others having tried them give their experience.

I have been battling with European foul brood for two years, my apiary being located about half a mile from Mr. Baker's. When I first discovered the disease I purchased a few leather-colored Italian queens, and with cells from these I requeened my

apiary. By winter they were, to all appearances, free from disease. As most of my colonies were weak, and the following spring was cold and unfavorable, the disease broke out anew. Many colonies showed but an occasional bad cell; but I decided to treat all that showed any disease. Nearly all the queens were full-blooded Italian, but mated to black or dark hybrid drones.

As Mr. Baker seemed to be having better success with Carniolans I procured some eggs and larvae from his bees, and raised cells with which I requeened nearly all of my apiary. They cleaned up nicely, as they had done the previous season, but in like manner the disease reappeared later on. These queens were also mismated, no doubt, though it is difficult to tell from the appearance of the bees. As there are hundreds of colonies in other apiaries, and in houses and rocks near by, it is a difficult undertaking to cure disease permanently or to get queens of any race purely mated. On this account I ordered two dozen Carniolan queens from the same breeder from whom Mr. Baker gets his. These were placed in strong and apparently healthy nuclei. Two were lost in introducing; and in the remaining twenty-two disease appeared in six before fall. I also ordered two more Italian queens at the same time, and later two Caucasians. One of the Italian colonies became slightly diseased late in the summer, but the Caucasians have shown no disease so far.

In the fall of 1911 I had 100 colonies. While the most of these contained mismated Italian queens there were several purely mated, and also one colony of Banats. The queen was sent me for trial by the late Walter M. Parrish, of Lawrence, Kansas. That Banat colony is the only one of the hundred which has never shown a trace of disease up to the present time. I expect to try the Banats out further the coming season. Of the large number of diseased colonies which I have had during the past two years, in many cases it became necessary to unite several into one before treating by the Alexander method.

Most of those which became infected during the past summer and fall were taken in hand upon the first appearance of disease, and were cured by caging the queen for two or three weeks, or by placing the brood above an excluder. The latter plan, which I believe was first mentioned by Percy Orton, of Northampton, N. Y., I consider the best of any I have tried for mild cases, provided the colony is strong and already has a desirable queen. This plan will prove a success, however, only during a honey-flow, as at times when no nectar is coming in the bees will allow the dead larvae to remain in the cells week after week, making no attempt to remove them.

As to the disease-resisting powers of the two races, my experience would indicate that the Italians are superior to the native blacks, and that Carniolans are equal to and possibly somewhat superior to the Italians. They are, however, by no means immune. Carniolans build up for our late flow better than the Italians, and for that reason I intend to continue keeping them, unless, after further trial, one of the other dark races should prove superior.

Monrovia, Cal., Jan. 1.

LEVI J. RAY.

My Experience in Early Brood-rearing

I remember being located in a high cold part of northern Vermont where it was necessary to build up colonies quickly in order to keep up with the season. I used the old-style ten-frame Langstroth hive. The first day after taking the bees from the cellar I used to examine every colony; and as I did this I had an extra hive in which I had fitted a tight movable partition. I took out the comb with the most honey in it, putting this comb at the side of this extra hive. If this hive was to face the east I put this comb on the south side. Next I selected a good brood-comb with some honey in it, and scrapped the cappings of this honey with a common table

fork, this making small holes in the cappings. I placed the two combs with brood in them next to a good brood comb with more or less honey in it. I used to scrape all combs with the fork, as this caused the bees to remove the honey which would stimulate them in brood-rearing. I spaced these five combs as near together as I could and leave a bee-space between them. I moved up the partition as close as I could and leave a bee-space. I then used a stick just fitting the entrance, and long enough to reach half way across the hive. After providing a narrow honey-board I shook the remaining combs in front of this five-frame hive, taking these combs and the old hive to the honey-house for safe keeping.

I took a large basket to the barn and filled it with chaff from the barn floor. I filled the empty side of this hive with chaff. I next took some old four-inch boards and made a frame or rim the exact size of the cap. I put this frame in place of the cap, and filled this extension level full of chaff, covering the honey-board three or four inches deep with chaff. I then placed the cap over all, and contracted the entrance to about one inch. I did this with all strong colonies, using fewer combs for the weaker ones. The hive being thus warm, the bees went to the field in large numbers, and were able to push breeding to the utmost.

I let them alone for about ten days. I then took the big basket, and with my hands removed most of the chaff, so I could move the partition. I always found the comb next to the partition filled with eggs and larvae, also the center combs well filled with brood. I took another comb from the store hive and scraped the cappings with the fork and placed this comb next to the partition, and covered all again with the chaff. I made all additions of comb to this warm side of the hive. I had to make these additions every few days. When I got the hive nearly full of combs I removed all the chaff and the partition, filling the hive with comb. I had to work fast to keep ahead of the bees, as they would get the swarming fever. There was work in this, but it paid.

I recollect having a lot of nuclei; and when a swarm came off I hived it with a nucleus; and after removing the cells from the old stock I returned the old queen. In about three weeks she would lead out another swarm. I have thus had three prime swarms from a single old colony, and a surplus besides.

Lyndon, Vt., Feb. 26. H. E. HARRINGTON.

Prospective Co-operative Beekeepers' Association in New Zealand

The chief drawback to our industry here is want of organization; but there is hope that this will be rectified shortly. A movement is on foot to establish a co-operative association in Canterbury, and if enough support is forthcoming a company will be formed in time for next season's crop. A Dominion association may be formed eventually, something on the lines of the National Association in America. A committee was appointed at last conference held in Wellington last August, and the members have been collecting information. This committee will submit a scheme at the next conference, and there is every prospect that a workable scheme will be evolved. Promises of support have been received from many of the leading beekeepers who intend to be present when the next conference is held. Prizes this season are low, probably on account of the crop being so much above the average. It is hoped that an export trade will be established; and if this is done, the local market will be relieved. A comprehensive scheme of advertising is contemplated in connection with the above, as honey is not as extensively used as it deserves to be.

Christchurch, N. Z.

E. G. WARD.

The Help of Bee Experts Wanted

I wish to suggest a possible opening in the way of what ought to be a good business. I keep bees because I must. My business demands it, yet it is impossible for me to give them necessary care or to look after treatment should brood diseases get among them. All through the country are farmer beekeepers who do not know how to work their bees. If a man were to come to me two or three times a season, certified as competent and trustworthy by a recognized authority, say the secretary of the National Association, or the State Inspector, I would gladly pay him three dollars for a day's work, or the work necessary, on my few stands. Perhaps I could better afford to pay five dollars than to let him pass on. So could others, though perhaps they would not.

It is possible that a bee expert could not develop a business at itinerant work; but I wish there were one whose territory would include my place. It would, of course, be absolutely essential that such a one be thoroughly grounded in the scientific knowledge of brood diseases, and competent to use the best methods, and exercise all the precautions necessary in treating and handling diseased colonies.

Carthage, Mo., Jan. 20. BENJAMIN C. AUTEN.

[Possibly some such plan could be worked out; but it occurs to us that in most parts of the country the traveling expense would be almost prohibitive.—Ed.]

Wire Cloth in Connection with the Alexander Plan for Making Increase

I wish to add one improvement on the Alexander plan of prevention of swarming as given on page 314, May 1. When the change is made with the queen in the new hive, and the excluder on, put a wire screen on the excluder, and then set on the hive body containing brood. Then shake most of the bees in front of the new hive. What are left will care for the brood, and the heat will pass from the colony below, and will be saved. This makes the colony shaken the same as a natural swarm—no brood to care for, and it forces twice as many bees into the field.

In eight days remove the screen and cut out all queen-cells. The upper colony or hive body containing brood should be given a small entrance in front when the cage is first made. I have tried the plan a number of times without the screen, but in almost every case too many bees would go above with the brood. This discourages the queen so that in a few cases she stops laying. The plan is not a success without the screen unless with an extra populous colony or with very warm weather.

Simi, Cal., May 19.

GEO. W. RICH.

A Lining for the Firebox of a Smoker

I have made a "discovery," or learned something, whichever way your old friends care to put it. Cut a piece of galvanized iron or good heavy tin as long as the circumference inside, and as wide as the depth of the fire-box on your smoker. Bend it into a hollow cylinder, and slip it into the fire-box. I have used a smoker thus for nearly a year, which had burned through before I put it in. If put in when the smoker is new it will certainly double the smoker's usefulness.

San Juan, Porto Rico, May 1. F. E. HARTWELL.

Alfalfa Does Well at High Altitude

On page 272, April 15, is an inquiry from J. W. Hontz, of Portales, N. M., regarding alfalfa at high altitudes. I am in the far-famed San Luis Valley, which is 50 miles wide by 100 miles long. The altitude is 7500 feet. Alfalfa does well, and the bees also do as well as I have ever seen anywhere.

Monte Vista, Cal., May 21.

Our Homes

A. I. ROOT

And God said, Behold, I have given you every herb yielding seed, which is upon the face of all the earth, and every tree, in the which is the fruit of a tree yielding seed: to you it shall be for meat.—GEN. 1:29.

In all they ways acknowledge him, and he shall direct thy paths.—PROV. 3:6.

Behold the birds of heaven, that they sow not, neither do they reap, nor gather into barns; and yet your heavenly Father feedeth them. Are ye not of much more value than they?—MATT. 6:26.

My good friends, I have made another "great discovery." While it is not exactly new, I am sure it is absolutely true. The greatest part of my discoveries are, as a rule, *not* exactly new; but they are new to me, and wonderfully precious, for I feel that they come straight from the hand of the great loving Father. Years ago, when my good friend Terry said so much about simple eating, uncooked food, etc., I took a trip over to his place expressly to partake of one meal just as he recommends and practices. Some of you will remember I told you about it in these pages. My digestion was a little out of order on that day, and I did not know whether his "menu" would agree with me or not. Terry and his wife, who were living by themselves, have only two meals a day. I think the first one is about eight o'clock, and the other about two in the afternoon. When I arrived there at the usual dinner time, and was told that the hygienic spread was for myself alone, I begged that it should be simply uncooked food just as Terry writes about, and *nothing else*. Well, just now I remember only three things on the table—rolled wheat, uncooked; evaporated peaches, uncooked, soaked in cold water; and butter. Friend Terry figured up the cost; and although I had a good square satisfying meal, the cost was only 6 cents. The wheat cost perhaps one cent, or a little more; the butter, one cent; but the peaches were so delicious, and I enjoyed them so much, that I ate about *four cents' worth*, and I do not know that I ever had a more satisfying meal, and, somewhat to my surprise, my digestion after it was perfect, with no disagreeable taste in my mouth afterward, *at all*. I do not remember what I had to drink; but I rather think it was some of Terry's beautiful cool filtered rain water; or it might have been roasted-wheat coffee; but I rather think it was just water.

Now, the reason I go into these details is as follows: Most of you know that my last meal for the day, say about five o'clock, consists only of apples—good ripe ones. In Florida I take a fair-sized grapefruit with my apples. I have tried mulberries, and,

in fact, almost all kinds of berries and fruit as a substitute for apples, but none of them seem to answer as well. After I got back from Florida I happened to go into the grocery where we get our supplies, and there I saw a case just opened of beautiful evaporated California peaches. The peaches were, of course, dried with the skins on. They were unusually large, and looked so tempting that I took a pound of them. One of my happy surprises was that they were only ten cents. As they were fancy stock I thought the price would be a good deal more. Well, remembering my experience at friend Terry's years ago, I told Mrs. Root to soak them in water and not stew them at all. At the end of 24 hours I cut one of the great luscious halves in two, and put the quarter of a peach in my mouth. I at once uttered an exclamation of surprise. I believe it was not only the most delicious peach, but the most delicious food of *any* sort I ever tasted. You may remember I said something in the same strain about that baked dasheen. Now, I do not know whether those peaches *were* something extra, or whether I had somewhat neglected to give uncooked peaches the attention they deserve. I remember that, after my experience at Terry's, we bought some ordinary peaches and soaked them, but I did not think very much of them. These peaches were not only uncooked, but no sugar was added. They were plenty sweet; but it was the sweetness that *God*, through the influence of the California sunshine, put into them. I asked Mrs. Root if she had tasted them. She said she had not, but she drank some of the water they were soaked in. By the way, I think she put about one pound of peaches to a quart of water. At her suggestion I poured some of the water (or "juice") into a teacup, and took a drink. Well, if the taste of the peach was a happy surprise, the peach juice, or, if you choose to call it so, peach cider, was a greater surprise. It certainly was the most delicious fruit drink, or drink of any kind, I ever tasted.* It did

*By the way, once or twice every summer, and several times in the winter, at my Florida home, I have taken a glass of soda at the soda-fountains just to see what they have that entices so many men, women, and children to spend their nickels in this way; and I have several times thought that perhaps the "high cost of living" was brought about largely by the nickels deposited at the soda-fountains. Who pays for this expensive apparatus to be seen in most of our drugstores that dispense ice cream and soda? It is the nickels; and if you watch the crowds as they take their various sodas, you will find a lot of children, and perhaps grown-up people, who look as if they did not have any nickels to spare. I may say the same in regard to coca-cola and Hires' root beer. Now, if the present generation demands some such drinks, usually called "fruit juices," for

not seem possible that a pound of peaches should diffuse its natural juices through that whole quart of water so as to make it so delicious and nourishing.*

That book, "Starving America," has a lot to say about uncooked food, or the food eaten just as God and the bright sunshine and the summer showers made it. With these dried peaches, of course we get every bit of the skin or peeling, fuzzy down and all. After eating these soaked peaches with my apples for a couple of weeks past I feel there is a special element in the peach skins and juice that nature demands. It furnishes those mineral salts about which the author of that book has so much to say.

Our first text tells us how God planned in the beginning to give our bodies the nourishment they need. You will notice the special mention of the *fruit* of the tree, and that "to you it shall be for meat." Not only did God intend fruit should be not only a large part of our daily food, but he meant that we should take it and eat it *just as he gave it*—peelings and all, the way the animals eat it. In other words, the expensive and wasteful fashion of throwing away one of the most important parts of our daily food is a great blunder. The water the peaches are soaked in contains a large part of the nourishing property of the peach. In the same way, the water in which your potatoes are soaked over night is rich and nourishing, containing mineral salts besides the starch, etc. The water the potatoes are *boiled* in is still more valuable. I know the women folks and the cook make objections; but by studying God's laws, and following

instance, remember that book, "Starving America," tells us the greater part of the ice-cream sodas have no fruit juice at all—only an imitation made mostly from the products or residue of our oil-refineries. Well, now, if such drinks are really *needed*, why not have fruit juice from the evaporated peaches instead of having them rot by the hundreds of tons? If you think I am mistaken, soak some evaporated peaches for 24 hours in pure cold water, and see if the drink is not ahead of any thing at the fountains. And this pure fruit-juice is straight from the hand of the loving Father.

* These peaches I am talking about were evidently very ripe when first spread out to be evaporated. Some of them, and I should say most of them, were probably soft and mushy; and I remember years ago in childhood of drying peaches out in the sun that were so soft that we just squeezed the stones out. On page 385 of our last issue, J. A. Green tells us of *hundreds of tons* of the finest peaches grown in the world rotted on the ground last August in Colorado. Now, if I am correct, evaporated peaches, where the work is properly done, can be kept safely year after year; and by soaking them in water according to Terry's plan you can have them *every day* in the year, almost as good, if not quite, as they were when picked from the trees. May God be praised for the beautiful peaches that are now produced, and for the improved methods of preserving them by evaporating so as to lose little or none of the deliciousness or healthfulness; and may God hasten the time when shorter cuts and less expensive cuts may be made from producer to consumer. How about "parcel post" for disposing of those "hundreds of tons" (in the shape of evaporated peaches) that were left to rot?

out the plans he has laid down, I should not be surprised if Terry and I would be alive, and well and happy, long after a lot of you who think you must follow *fashion* in eating (as well as in dress) are dead and gone. In fact, Terry and I can even now, when we are in our 70's, look around and see *hundreds* who were born some time after we were, that have died—"worn out," so the world says.

Let us now touch a little on the second of our texts—"In all thy ways acknowledge him, and he shall direct thy paths." God will direct us all as to what we shall eat and how we shall live, just as well as in spiritual matters, if we "acknowledge him" and confess that his wisdom is greater than ours, and learn to take the food he has provided as he gave it, straight "from the producer to the consumer." We shall not only live long, but we shall be well and happy.

Of course, we can not eat *every* thing uncooked—that is, we can not very well at the present time; but as Terry and the author of that other book say emphatically, we should endeavor to have a *large part* of our every-day food uncooked. Let God's *sunshine* do the cooking. You may remember there is quite a nice book out now already entitled "Sun-cooked Food."

In the matter of drink, God sends the needed water in most localities straight down from the clouds—you might say straight down from heaven, and say it truthfully; but as it is inconvenient to get it straight from the clouds, especially when it does not rain, the duty devolves on us of *keeping* rain water. Now, in order to be sure that the water I drink is pure and wholesome, I drink only boiled rain water. I do not care very much about having it cold or very cold—so it is pure and clean, free from all vegetable matter, especially during hot weather. I have repeatedly drank water right from the cistern, say for a couple of weeks, and watched its effects. Then I would take the same water and have it boiled, and (of course) cooled off. I have not used *hot* water of late unless I eat something I ought not to eat, or overeat. Then a good big drink of hot water until it starts a good perspiration seems to be beneficial. I usually drink half a cupful of milk at my meals. Milk, like fruit, is the food God provided and intended for us, especially the little ones. Great pains is now being taken, I think, almost *all over the world*, to have the milk as well as eggs fresh and pure. Why, it is just "fun to live" when you are following God's plans, and when you let him direct and advise.

Sometimes it sounds extravagant to hear

Terry keep insisting that correct living will cure you, no matter *what* the trouble is; but the longer I live, the more I am convinced he is right. Of course, we are all liable to accidents; and in such a case or at such a time we need the advice and skill of our expert physicians and surgeons. May God be praised for what has been accomplished, and is now being accomplished more and more every day in the line of intelligent surgery.

I suppose it will not be out of place to suggest in this talk that, aside from uncooked food and pure water to drink, we need to keep our bodies clean. Every inch of my body is washed with pure soft water, and well rubbed till dry, every day of my life, and I enjoy it, and would not think of taking up my tasks without it.

One thing more: Almost every day of my life I work at something until the perspiration starts through almost every pore of my skin, and until I feel tired enough to sit down at my desk. Last, but not least, I take a short nap before my noonday meals so that I rarely ever sit down at any meal exhausted or tired out. Of course, when I get up in the morning, and have my breakfast between five and six, I am in good trim because of my restful sleep; and this reminds me that when one gets his *digestion* in proper trim, as God intended it should be by the use of wholesome food, and not too much of it, there is almost no trouble about sleeping. When I have a large lot of books and papers that I feel as if I *must* glance over, at least hastily, I take another nap in the evening before going to my task, and then go to bed about ten o'clock; then I go to sleep instantly, and do not remember any thing or know any thing until toward five o'clock next morning.

Now for my concluding text. The dear Savior reminds us that God cares for the fowls of the air. Although they do not reap nor gather into barns, yet our heavenly Father feeds them. He tells them by instinct where and how to get proper and wholesome food. Then he asks the question, "Are not *we*, the crowning act of his creation, of more *consequence* than the birds of the air?" If he makes provision for them, has he not, in his infinite wisdom and loving kindness, also made provision for us? Did he intend we should be sick and ailing as so many are? *Should* we be ailing if we used the common sense he has implanted in us all, in studying out what his plans are?

As warm weather comes on, and I begin to protest against the fashionable way of clothing, I meet with remonstrance; and I am told that we must, at least to a reasonable extent, look like other people. Peter

said, you will remember, in olden time, that we should obey God rather than man; and when fashion conflicts with health, I for one propose, at least to a certain extent, being *out* of fashion. The fowls of the air live out of doors; and I am sure God intended we should be out of doors at least a great part of our time. When any thing takes us indoors and keeps us at least a good many hours of the day under the influence of artificial heat, and without a great abundance of outdoor air, we have no right to expect to gain the blessings of health. People are committing suicide; in fact, the suicide mania is increasing if any thing; and I feel sure a lot commit suicide because they are disregarding God's laws.

There is not so much complaint, just now, about people being out of work. Everybody—good, bad, and indifferent, has a chance to work if he wants to; and I am sure it was God's plan that we should be busy, using our muscles and brains during all our working hours. I picked up a health journal a few hours ago, and read of a man who rushed into a doctor's office, and told the doctor he would give him fifty dollars, a hundred dollars, or even one thousand dollars, if he would make him well. At the same time this man's breath was reeking with the fumes of whisky and tobacco, and his face gave abundant evidence of excesses of every sort. When the doctor assured him there was no permanent help or hope unless he would leave off *all* of his bad habits, he got into a rage, and declared that if this particular doctor could not *give* him something he would hunt up a doctor who would. There is no help for such people along the line of God's plans. "Whatsoever a man soweth, that shall he also reap."

THE JAPANESE PROBLEM.

Quite likely I am too poorly posted to pass an opinion on the matter in question; but notwithstanding I wish to have a little say in regard to the matter. We are sending missionaries at great expense all over the world wherever there is sinful and suffering humanity; and although the great business world for a considerable time did not seem to recognize the importance of missionary enterprises, I am glad to say that within a few years or so things have changed. The skeptics and agnostics, and the business part of humanity (that has been so greedy for gold) just now are recognizing what the missionaries are doing to develop and civilize the uttermost parts of the earth. For a long time heathen nations held aloof, and could not be induced even to take notice of what the missionary

had to present. A little later, however, the current changed and began to go the other way; and these very heathen, both saints and sinners, began flocking to our shores in such numbers that there is talk about putting a stop to it; and while our United States is composed so largely of all tribes and colors of humanity it becomes a little difficult for those of us who are "born Yankees" to dictate for the rest of our people. Well, now, contrast the difference not only in expense but in the facility with which we can convert our *next-door neighbors*, compared with, for instance, the inhabitants of the islands of the sea on the other side of the globe. Ought we not rather to *rejoice* at the opportunity it affords us to spread the gospel among people of all nations who are sprinkled like salt throughout our whole domain in "the land of the free and the home of the brave?"

Ten years ago or more Mrs. Root and I paid a visit to some friends in San Francisco. They had a Japanese cook; and the lady of the house said he took *entire charge* of the dinner; and every one of us could testify that it was gotten up in fine style. The cooking was superb in every particular; and this young "Jap," as spry as a cat, did the whole of the work. So far as I can gather from the papers, the people of California object to the Japanese because they not only work *cheaper*, but are *better skilled* in housework and ever so many other things. California does not want them, because they stand in the way of—well, I should say of "bigger wages and shorter hours." I have been wondering what our good women folks who are obliged to employ hired help have to say in regard to the matter. Lots of industries are being abandoned (and this includes even the "chicken business") because faithful and skilled help costs so much. I would by all means put a stop to Japanese men coming over here for a little while, leaving their families in Japan. If I am correct, Arizona cuts off the Japanese unless they bring their *wives and children*, and become naturalized. There seems to be some good sense in such a course. It rejoices my heart to see that the *American Issue* for May 17 indorses my sentiment, at least to a great degree. Read the following:

CALIFORNIA AND THE JAPS.

In California 334 Japanese farmers are provoking the soil into growing things for the common good.

These Japs beat the world in intensive farming. They are sober, tremendously industrious, and have the science of raising much crop from a wee bit of land reduced to a science.

They bathe every day, and eat fresh vegetables, nuts, and fruit instead of beefsteak at 28 cts. a pound.

The American farmers are beaten at their own game, and call upon the legislature to help them out

by eliminating the Japs from the farming industry.

It is suggested that these 334 Jap farmers embark in the saloon business. Let them embark in the business of skinning the poor of their wages, the business of getting people drunk, and sending them home to beat their wives and pound their children.

Let these Jap farmers embark in the business of filling the stomachs of the city poor with forty-rod lightning instead of cabbages and potatoes. Let them embark in the business of debauching California citizenship, in the business of breaking up California homes, sending California boys to prison, and the girls to hell.

The California legislature won't kick on this, provided the Japs deliver over a portion of the profits in the form of license money.

If the little Japs will engage in the business of raising Hades instead of potatoes, all of these international complications will have been abated.

Now, dear friends, shall we not extend a hand of welcome to any sort of humanity, white, black, or *yellow*, if they come over here and become one of us, obey our laws, and bring their wives and children?

MISSIONARY WORK IN BARBADOS.

We have been fondly congratulating ourselves that cannibalism was about wiped off the face of the earth, and that the gospel of Jesus Christ had so thoroughly penetrated every remote spot that in the near future starvation, and cruelty of every sort, would soon be done away with as they are here in America, at least as a general rule. Below is a letter, however, from Barbadoes that should stir up not only America but the whole wide world. I am glad our good friend Hutchinson has taken the pains to inform us of such terrible things; and I hope this printed letter may be the means of awakening all mankind to what is still going on in some remote parts of the globe.

Dear Mr. Root:—At the close of another year I have to return your firm my hearty thanks for their kindness in sending me GLEANINGS for the previous 12 months. An equal debt of thanks is due to you, as senior partner, and with a preponderating vote in the counsels of the firm. It is a great pleasure to be able to render such thanks, as GLEANINGS has always a special welcome in my house; and your steady fight for righteousness is always of great interest.

During the year we have been interested in this island in the Putumago atrocities, as many of our people were at work in that region. What attracted public gaze to it, was, a man settled here, married, opened a hotel, which he gave somewhere, north or south, the doubtful compliment of naming after it. But Peru telegraphed here to arrest this proprietor of "The America," and the allegations made at his trial were something awful. Beating individual Indians to death was only pleasurable compared with other horrors. On one occasion he tied up 20 Indians, and flogged them. Then from morning to evening they were kept tied up under his house. In the evening he brought them out again, flogged more flesh off their bones, then laid them out on the ground, poured kerosene oil over them, covered them with wood, and set them on fire. That fend in human form actually got off through the indifference of the Peruvian government!

W. G. HUTCHINSON.

St. Joseph Rectory, Barbados, Dec. 23.

Poultry Department

SITTING HENS, AND HOW TO MANAGE THEM.

There is an article by our good friend Stoddard in the *American Poultry Journal* that is worth ten dollars to me. I have read it over three times, and I am going to read it again. The article certainly ought to be worth the subscription price of the journal to *any one* interested in poultry. If you do not subscribe right out for a year, send for the June number at least, and read Stoddard's two articles in that issue. I know friend Stoddard is getting to be an old man like myself; and I have criticised him somewhat in times past on account of the complicated machinery he recommends. But notwithstanding all this, I believe our old friend has studied chickens more than any other writer who is living and making "things hustle" in chicken matters at the present day. The article that I have read with so much interest is on the value of poultry inventions, and is particularly about sitting hens. See the following extract:

I would a hundred times rather invent something that will aid in producing food for generations to come than create the advanced types of monstrosities in fowls and pigeons that have appeared in England for a century past all put together, were it possible for one person to do this.

A while ago I published in this magazine a description of what I named the "duplicate system" of yards for management of sitting hens, which method pleased me so much that I felt like jumping over a two-story house. I thought it was not capable of improvement. It has worked like a charm with me and saved endless labor and vexation of spirit; and had my sitters been of a better breed, with more uniformity of disposition, it would have worked still better. To find the very best breed for sitting purposes, in the sub-tropics, is a consummation devoutly to be wished. Climate is evidently not just right for heavy breeds.

I kept calling on poultrymen for years and years to invent good methods of taking care of hens engaged in sitting, but my appeals were largely in vain. In all, volumes of diatribes against mother hens have been written, though they are among objects most worthy of admiration found in the entire realm of animal life below the human race. "As a hen gathereth her chickens under her wings" suggests a picture than which there can be no finer in nature in the eyes of her true votaries.

The latest depreciation of the use of sitting birds I have seen is in the April issue of the *Poultry Advocate*, from a writer who gives a very valuable article, and is in part as follows:

"As the nests were attended to, the hens fed and watered, there were broken eggs discovered. This called for fresh nest-filling, washing of the eggs that remained whole, and sometimes the getting of a fresh sitter. One of the hard things in hatching with hens is the bowel trouble that comes from feeding injured corn to them. . . . More hens soil their nests, more chicks die of bowel trouble, from musty corn, than all other causes. If in any doubt as to the corn—and you can not get other—bake it in the kitchen oven till the color of it is slightly darkened. Then cool and keep in dry box till needed."

The baking advice is excellent; but this writer has missed the most general cause of bowel trouble. It occurs from lack of exercise in twenty cases to

one of musty corn. Sitters closely confined are afflicted as described time and time again, while their flock mates not engaged in sitting, but of the same age and breed, and fed on the same corn exactly, are exempt.

Study the actions of a sitter off her nest of her own will, with plenty of room to run and get up full speed, and fly to the fence top, or upon some other elevated object, and down again, and bustle around generally, and hunt up her flock for a short visit, and race back near her nest, then scamper away again. Once I thought these antics were merely manifestations of delight at respite from the irksome restraint of sitting, but now I know better. They are fraught with deep meaning like many other habits of animals. Probably hens which steal their nests do not have bowel trouble and foul their nests in one case in a thousand. I will warrant not a reader of this magazine ever knew of such a case.

TRIALS AND TRIBULATIONS.

Our writer's other vexations are familiar to readers. Hens do not return to their proper nests, for instance. The hen which steals her nest makes no such mistake. Her brain is loaded to the limit with thoughts about her nest, and her previous nest. She spent lots of time considering the matter in the first place, and compared various localities before she laid an egg. All her actions proceed like clockwork if she is not "taken off by hand" and "put back," and stirred up and confused generally. The more she is handled and made anxious about her nest, the worse she behaves. Even if she is quite a tame specimen, and not nervous on ordinary occasions, she is excited when the sitting fever is on. The love for her eggs is almost as strong as love for actual chicks, and all the fine program of nature is disarranged by a "brain storm."

What if some way could be contrived by which sitters could be let severely alone after eggs were assigned, all the time till hatching begins, just as if they had stolen their nests! Eureka! All fussing not only menaces success and vexes the poultryman, but takes up so much time as to mean good-by to profits.

Contrive some way of letting sitters alone, and they will regularly air and turn their eggs and carry out the whole of nature's exquisite program just as the one which steals her nest does.

You perhaps gather from the above that both writers refer to an arrangement for confining the sitting hen to a little yard or yards. Let me digress enough to say that it is virtually the same thing we frequently see advertised—the "natural-hen incubator, for only \$3.00." I have shown it up again and again in years past; but still the advertisements are seen in a great part of our poultry journals. Briefly, the man has no incubator to sell at \$3.00 or any other price, and he never had one. All he has to sell is a single sheet of paper—price \$1.00; and if you do not buy immediately he will come down to 50 cents and then to 25, for his wonderful sheet of paper. He just tells how to give each sitting hen a little doorway where she can eat and drink and take a little exercise. Now, friend Stoddard's plan as described in the June number of the *American Poultry Journal* is to make these yards a good deal longer. They may be three feet wide or less, and as long as

your ground will admit—the longer the better. Friend Stoddard recommends letting sitting hens severely alone. Instead of annoying them and getting them out of temper by human intervention, he lets the great God who made them do all the managing, or, in other words, he lets them follow out their own wonderful instinct. Let me digress a little right here:

Along about the first of April, in our Florida home, Wesley announced that a Leghorn hen had just come out of the brush with a fine brood of chickens. We went down, picked up the hen, gathered up her fifteen chicks, and put them in a coop. She behaved so nicely that I began to think she was a jewel of a mother. By some mishap, however, one of the chicks got out of the box just as we thought every thing was all right for the night; and when I tried to catch the chick her motherly instincts all at once were aroused. She got out of the box, and I had one of the biggest fights I ever had with a sitting hen. We finally got her put back, and I kept her several days shut in a coop. Finally I decided to let her go out for exercise. Her first performance was to dig the mulch away from the fruit-trees in our dooryard, sending the dried Bermuda grass "sky high" in her search for crickets for her brood of fifteen. When we "shooed" her out if the dooryard she got over into the cornfield; and when the chicks were a week old, she and they had been pretty much all over the premises. The fences of the convergent poultry-yard were no obstacles to her at all. In fact, her daily plan of getting over one particularly high fence was to fly up to a limb on a pine tree, twenty feet or more from the ground. She would fly right straight up and alight on that limb, and, after resting a while, sail down or "glide" as the flying-machine men do. The chicks were very soon following her everywhere. They did not need any feeding nor any thing else, apparently, for God's earth was fruitful enough and broad enough to give them all things needed. By the way, is there not here a lesson for poor humanity? If the fathers and mothers of our land had the grip and faith in their own muscles, and the ability to see what God has spread out before us, I do not think there would be much complaint about "the high cost of living."

Well, when we came away Mrs. Root declared that this particular hen would have to be sold with the rest of the two-year-old layers. The chicks were then about three weeks old; but they had become so independent that they did not seem to mind the loss of their mother at all. They were the last to get home at night so I could shut

them up, and about the first to get out in the morning. Now, Providence permitting, I am going to raise a strain of chickens from these fifteen, even if they do defy fences and every other obstruction. I take it the little family is *still* unbroken. See the following letter.

Mrs. A. I. Root:—Wesley came last Saturday, the 10th, dug the Irish potatoes, and sold the best of them and put the rest into the barrel in the cellar, and covered them with dry sand and put wire screen over to keep rats out. He dressed out the dasheens, and sprayed the chicken-house with kerosene to kill the mites. My dasheen looks very well, but rain would do them good. The fifteen little chicks seem to be doing well. They come over to see us every day and gather whatever bugs they can find. There is nothing they can harm, and we like to have them catch the bugs.

Bradentown, Fla., May 19. C. L. HARRISON.

FRIEND STODDARD'S LATEST INVENTION.

You will notice in the above extract he has been studying on some plan of letting a sitting hen remain right on the nest where she first wanted to sit. She is not only to have a nest all to herself, but she is to have liberty to go off and fly on top of the fences or even on top of the barn if she chooses, and come back when she is ready. Come to think of it, however, she can not fly up on top of the barn, for this long narrow yard is to be covered overhead with poultry-netting or a few boards to give shade, say over the nest-box. Now for his plan for accomplishing all this or letting the poultry themselves accomplish it: The hens that lay the eggs to be used for hatching are in one yard. Adjoining this yard are the poultry-nests, each one having a runway, as I have explained. Of course we use nests enough (each with its little yard) so as to have one for each of the sitting hens, more or less. Each nest has a little door. If you close all but one, and there are no other available nests in the yard, or connected with it, your flock of probably 12 or 25 will all lay in that nest. If the nest is a good-sized one, shaded and ventilated, and at the same time darkened and secluded, a dozen hens may lay their eggs in it during the day.

There is one nest in my yard that the hens all seem to prefer, and several times I have found eleven eggs in that nest. By the way, down in Florida hens frequently begin to lay between six and seven o'clock in the morning, and quite often there are more or less eggs laid as late as four o'clock or even later. It seems to be a natural instinct on the part of the hens to lay where there is a nestful. You may recall the fact that I could not get the hens to lay in my newly planned nest until I put three or four eggs, *just laid*, in that nest. After that, they would lay there right along. Well, after the whole 12 or 25 have got a

fashion of laying in this one nest, especially if you have chosen a breed of sitters, pretty soon you will find there will be a hen that tries to sit on the eggs all night, and will fight if you try to put her off. Do not get her off. Do not annoy nor trouble her. Shut up that little door and open the one further along. As the pens are exactly alike, your flock of layers will never know the difference; and as soon as another hen wants to sit, shut her in and open the other doors, and so on till you have as many sitting hens as you want. If you have some choice eggs, put them in, say, after dark, disturbing her as little as possible. The nests, you will notice, are near the door where the fowls go in to lay. At the opposite end of these narrow yards you have some corn, dripping water, shells and grit, and the dust baths—that is, if the ground is not already suitable for a dust bath. If you want a diagram of the whole arrangement, send for that June number of the *American Poultry Journal*, 542 South Dearborn St., Chicago.

Whatsoever a man soweth, that shall he also reap.
—GAL. 6:7.

FORTY CARLOADS OF POULTRY IN NEW YORK CITY WAITING ON THE STRIKE.

The particulars of the above I find in the *Cincinnati Packer* for May 24. The only reason why I give it place in our Poultry Department is that the New York buyers claim that these carloads of poultry were made very hungry, and then all at once given all the corn and *sand* they would eat. The buyer registers three specific complaints: First, that poultry is starved on its way from the West, then is overfed with

sand and corn just before arriving in Jersey City, the extra weight of sand in the crops increasing the weight fully 15 per cent, which is a total loss to the buyer, and they (the buyers) have finally made a kick against that way of "doing business." Now, I do not know how true this is; but it seems to me almost incredible that it is possible to feed chickens *sand* until it represents fifteen per cent of their weight. Of course, this would mean *live weight*. But it is true that every man who is even a party to that kind of business should "reap" what is justly due him. If such is really the case, they had better get our good friend Billy Sunday to hold some meetings among the chicken men, and preach on the text that "honesty is the best policy." In fact, it is the only policy that will succeed in business year after year, and win heaven in the end.

"Wherefore do ye spend money for that which is not bread? and your labor for that which satisfieth not?"

Some time ago I read of a lot of poultry in California that seemed to be so unusually heavy that the buyer opened several, and found a lot of bullets had been pushed down their throats—probably after the fowls had been killed. Some of us have been congratulating ourselves that the people who work out in the open air, or, say, the "honest old farmer" and those who raise chickens and keep bees, are more honest than the city dwellers—middlemen, for instance. By the way, I wonder if it is true that *beekeepers*, any of them, are trying to work in "sand and leaden bullets" until their crops of *honey* are "podded out." God forbid.

High-pressure Gardening

SWEET CORN—A CHOICE STRAIN; HOW TO TREAT THE SEED TO KEEP OFF GRUBS, CROWS, ETC.

Some years ago a reader of *GLEANINGS* sent us some sweet corn that we folks at Rootville decided was ahead of any thing else we had ever gotten hold of. Well, we finally lost the seed, but the friend who sent it was kind enough to send us some more that got here just at planting time. Here is what he says about it:

The corn I sent you is the Gilmore. Some years ago I sent you some of it, and you said it was the best corn you ever saw. It is a cross between a sweet corn and the Tuscarora as host. Not a thing will touch grain or plant. Since 1847 I have prepared corn thus: For one peck of seed, immerse for a minute or less in hot or boiling water; drain, and immediately add two tablespoonfuls of pine tar. Stir briskly until every grain is coated with tar. Then add lime to dry and prevent sticking together. Please publish this; for if farmers practice it, and

have good seed they will always have a good crop. It will add millions to the country.

MOSES GILMORE.

THE WAY THEY TEACH "HIGH-PRESSURE" GARDENING ON THE GROUNDS OF MENGU HIGH SCHOOL, UGANDA, AFRICA.
SEE PAGE 416.

Shortly after my talk about simplicity in dress, in our issue for May 1, I noticed a picture in the Planet Jr. catalog, and the proprietors of these celebrated hand cultivators have kindly loaned me the cut. I think I mentioned once that, while in Florida during July and August, I used to go out in the garden and sometimes work quite a spell in my night dress. As the poultry are all shut up tight during the night in order to let them out at the "peep of dawn" I was not only *obliged* to be up quite a spell

before the rest of the neighborhood, but I rather enjoyed it; and I remember thinking what a pity it was that folks could not go about all day in night dresses—that is, when the temperature is up to 80 or 85; and it also occurred to me that many of us would accomplish very much more if we were unhampered by fashion and clothing we do not need. We do not *know* at present just

how much better off we should be. I can not tell exactly, by looking at the picture; but my impression is that some of the pupils(?) are well along in years. My good friends who run hand cultivators out in the fields, would it not be a luxury to be permitted to dress like that chap holding the cultivator on the right hand of the picture?

Temperance

ANOTHER STRAW WHICH SHOWS WHICH WAY
THE WIND IS BLOWING; SALOONS BAN-
ISHED FROM THE PANAMA CANAL ZONE.

We clip the following from the *Union Signal*:

A SALOONLESS ZONE; NO SALOON LICENSES TO BE
ISSUED IN THE CANAL ZONE AFTER JULY 1, 1913.
BY ABBIE B. HILLERMAN,

*National W. C. T. U. Representative
in Canal Zone.*

At a meeting of the Isthmian Canal Commissioners held April 24, 1913, the following resolution was adopted: "Resolved, That no license for the sale of intoxicating liquors in the Canal Zone be granted by the Commission for any period beginning on or after July 1, 1913." During the present fiscal year there were five Canal Zone settlements where saloons were permitted; namely, New Gatune, Gorgona, Matachin, Empire, and Culebra. Thirty-eight licenses were granted in these places last year. The proximity of Empire to Camp Otis made it advisable to stop granting licenses there, and the same reason applies to Culebra, according to the *Canal Record*, another argument against the canteen in the army.

The highest number of licenses issued at any time was sixty-three in 1908 and 1909. At the present time there are thirty-five. A license fee of \$100 per month was required; and for the period of six years during the operation of this system the sum of \$326,200 has been received from this source by the government, represented by the Isthmian Canal Commissioners. This only shows the financial side. The toll of blighted manhood and ruined characters which has been collected by the rum traffic is appalling. Three great American breweries are there.

We are thankful that there will be one exception at least to the statement that "The American saloon follows the American flag." With the eyes of the world centered upon this strip of land which is so soon to be the great ocean highway of nations, this action is most opportune. We believe that the thousands of pages of temperance literature sent to this section by the National W. C. T. U., together with the influence of temperance sentiment at home, has had some part in this victory. It is certainly in harmony with the views and actions of the President of the United States and his cabinet.

May the Lord be praised for the above. And it is my impression that the W. C. T. U. has had much to do with bringing about this happy result; and thank the Lord, also, for a President whose life and character are in harmony with the above.

The crowning engineering achievement of the world can not afford to be handicapped just at its completion by the presence of the saloon business and the liquor-traffic.

THE MILLENNIUM COMING THROUGH OUR
GREAT RAILWAYS.

May be the above heading is pretty strong; but our great railway companies are at least having something to do with it. See page 234 of our issue for May 1. Then read the following letter.

Mr. A. I. Root:—In the May 1st issue of GLEANINGS you quote a letter issued by a railroad claim agent to their employees, and ask some one to send you the name of the road. I am glad to say this letter was sent out by Mr. C. W. Egan, claim agent for the B. & O. R. R., Baltimore, Md. The B. & O., besides being the first road in this country, was the first to issue an order forbidding their employees drinking intoxicating liquors or frequenting places where they are sold, either while on or off duty. I am glad to see most of the railroads are requiring the same from their employees now.

I have been employed by this company for about fifteen years as telegraph operator, and am located at present near the historic town of Harper's Ferry, W. Va. I enjoy your Home talks very much, and hope you may live to keep up the good work for many more years.

Keller, W. V., May 29.

W. F. ANDES.

Hurrah for the B. & O. Railway Co.!
"Long may they wave"!

CIGARETTES AND CONTAGIOUS DISEASES.

We clip the following from the *South Dakota Farmer*:

Agents of the New York Factory Inspection Commission have made the discovery that many thousands of high-grade cigarettes are made in tenement houses among which contagious diseases are found. The woman of the house employs odd moments between housework and caring for sick children in rolling these "coffin nails," licking them with her tongue to hold the paper together.

This disclosure may not suggest any thing to the youth and their elders who smoke cigarettes, but it ought to.

And once more let me ask why the Health Commission of the United States, while waging war on pernicious and habit-forming drugs, does not turn its attention (and guns) toward cigarettes and the whole cigarette business. Is there not reason for it aside from what is referred to in the above clipping. Making idiots of our boys is perhaps even worse than sending them to their coffins through contagion.

Gleanings in Bee Culture

VOL. XLI.

JULY 1, 1913

NO. 13

Editorial

IN a note just received from our California correspondent, Mr. P. C. Chadwick, we learn that the Governor failed to approve the new foul-brood law, so the long fight that the California beekeepers have been going through must be fought over again in all probability. Further particulars will be given in our July 15th issue.

OUR COVER PICTURE.

APPROPRIATE to the general subject of this special number is our cover picture showing a lot of fancy and No. 1 sections. At first sight one would be inclined to call some of these No. 2's, judging from the photograph; but it must be remembered that a picture always shows comb honey worse than it really is.

HONEY-CROP CONDITIONS; CLOVER ABUNDANT AND INDICATIONS POINT TO A RECORD-BREAKING YIELD FROM IT.

REPORTS in general would indicate that this has been the greatest year for clover honey we have had for many years; but the frosty weather along in May and early June nipped the clovers in spots. Drouth has likewise checked the flow in localities in Illinois and New York. The reports of an excellent flow are particularly numerous from Ohio, and very good from Indiana, Michigan, and Pennsylvania; and in West Virginia and Tennessee the reports are from good to bad. In some localities the drouth that threatened to stop the flow of nectar altogether has been relieved by heavy rains. Good reports come from Southwest Texas, from Missouri, particularly in the Ozark region. Reports are fair from Iowa, and in the New England States the yield has been fair to excellent. In New York it was feared the flow would be a failure from drouth; but later reports indicate that the drouth has been broken, and that there is some prospect of honey yet. Reports as yet are meager from Minnesota and Wisconsin. Similarly we have heard but little

from the alfalfa irrigated regions. There is nothing to indicate, however, that the season will be below normal. Reports from California indicate that the season has been poor all over that State, with one exception, and that is from Santa Barbara Co.

Just now it appears as if this were going to be a great clover year. It is too early yet to make a positive statement; but conditions now seem to indicate that there will be a record yield from clover.

HONEY PRODUCTION AT THE MEDINA APIARIES

THESE are busy days at our Medina yard. There has been a remarkable bloom of clover, and it is still on this 25th day of June. Indeed, we do not remember a time when clover seemed to have yielded by the tubfuls as it does this season, unless it was the year when A. I. Root secured his enormous yield of extracted honey in the early 70's. It was at that time that he was proposing to build a big cistern of 100 barrels capacity for the storage of his extracted honey. He borrowed all wash-boilers and tubs in that section of the town, and had them all full. Perhaps this dream of his early days was a little wild; but it will be remembered he was only a novice then, and he continued to be Novice for several years, writing under that *nom de plume* for the old *American Bee Journal*.

So heavy has been the honey-flow that Mr. Pritchard has complained that the bees would actually clean out his grafting-cups and fill them with honey. Some one facetiously remarked that if a few tin cups could be passed around in some of the supers the bees would fill them with honey. Great scheme!

Swarming has been going on at a furious rate. Our auto truck with our gang of four men has been kept busy going back and forth putting on supers, the men shinning up trees after swarms. Even the editorial force has been called into the field. On more than one occasion the editor could have been seen up in a tree chasing after a swarm.

At one of our yards Mr. Pritchard and ouself found that cell-builders seemed bent on making us a lot of trouble. You know that cell-builders have to be kept up to a high state of prosperity. The colonies have to be extraordinarily strong; and when honey is coming in at a furious rate, and bees building cells, is it any wonder that they swarm?

At the present time it is very dry in our locality, but not dry enough to prevent a copious flow of honey; but unless we can get a good soaking rain, our crop will be cut square in two.

We hope to have some photos a little later that will show the operations here at Medina of the automobile truck in action. Say! that motor truck is proving to be all that we wished for it. It practically puts all of our eight yards together where our men can take care of them, and yet at the same time it allows us the advantage of immense fields for honey production. In this connection some of our yards have had a soaking rain, while the others, near our home yard, remained high and dry. That, again, shows the wisdom of scattering our yards. More anon.

DEATH OF ANOTHER PIONEER BEEKEEPER; A
STRENUOUS ADVOCATE OF HAVING ALL
THE CELLS SEALED BEFORE EX-
TRACTING.

OUR old friend Dan White, of New London, Ohio, died June 2. He was known to the beekeeping world as perhaps one of the most strenuous advocates of bee-ripened extracted honey. He wrote a number of articles denouncing the policy of extracting before *all* the cells are sealed. Especially did he condemn the plan of extracting before the honey is ripe and finishing the ripening in open vats.

He built up a fine local trade for his extracted honey. It was so good, he said, that he had no trouble in disposing of all he could produce, as his old customers would continue to call for it year after year, knowing it had quality.

Our friend had a unique personality. He had a strong rugged appearance and an honest face. His plan of selling was to go around to a town and give away samples of his extracted honey, saying he was not selling any thing that day. Then he would hand out a blank postal card with his name and address on it, and say to them, "If you want any of this good honey, put your name and address on this card, and when I come with my delivery wagon I will bring what you want." The next day he would get a string of postal cards that would call for

a wagonload of honey. He never had to drum up that trade any more, because the quality of the goods was his traveling salesman.

This method of selling, which has proved to be so effective on the part of others, will be advocated by the A B C and X Y Z of Bee Culture as long as we have control of it; and Mr. White's short and convincing letter in connection therewith will continue also.

THE CONVENTION AT AMHERST, MASS.

THERE was held at Amherst, Mass., on the 11th and 12th of June, immediately following the close of the apicultural school-work under Dr. Gates, a convention which in point of valuable, helpful discussion, was the equal of any meeting, National or State, we have ever attended. There were students from other States as well as Massachusetts. There were also beekeepers of prominence as well as scientific men from the college who took part on the program. Dr. Gates showed that he is a master in getting up a program, and if he has any thing to do with preparing the official program for the next convention of the National, the members of that organization may rest assured that the convention will be well worth attending.

It will be almost impossible, in the limited space at our disposal, to give any thing like an adequate and complete report of the Amherst meeting; and all we will attempt to do will be to refer briefly to some points brought out by only a few of the speakers.

We should, perhaps, state in advance that the discussions that took place in one of the college class-rooms were followed up by actual demonstrations at the college apiary and in the college bee and extracting house. The students were, therefore, able not only to take in the theoretical but the practical side of the industry at one and the same meeting. And this reminds us that more of our conventions should have more practical work—in other words, there should be facilities provided whereby the various speakers can illustrate their addresses by the things themselves. There is nothing like showing the actual operation: and we are of the opinion that those who attended the Amherst meeting came away with a very clear conception of the methods and things described.

BEEES ALMOST THE ONLY AGENCY FOR POLLIN-
ATING FRUIT-TREES.

We arrived a little late for the first session, but in time to hear the address of Prof. F. A. Waugh, of the Massachusetts Agricultural College, on the pollination of

fruits. In this connection it may be well to mention that Prof. Waugh is a national authority on fruit-growing. He is the author of a practical work on the American apple-orchard,* and also a producer of fruit himself. The readers of the A B C and X Y Z of Bee Culture will remember a quotation from him on the subject of spraying fruit-trees, and his caution against applying such sprays when the trees are in bloom. We asked Prof. Waugh to give us his complete address at some future time; but at this time we may state that he gave some conclusive evidence showing that the honeybee was the principal and almost the only agent in the pollination of fruit-trees. He referred to the claim to the effect that there are other agencies than bees for doing this work, principally among which is the wind. He had taken pieces of glass, coated them with vaseline, and secured them on the windward side of fruit-trees in full bloom, at a distance that would be about equal to another tree that is supposed to receive wind pollination. He found that these glass plates, smeared as they were with grease, received almost no pollen dust, even when the wind blew through the trees in full bloom in the direction of the plates. He further stated that there are practically no insects except bees that are flying when fruit-trees are in bloom, and that nearly all the cross-pollination that is effected at all is through the agency of the bees. There are some varieties, he said, that are self pollinating; but even these varieties have more and better fruit when bees are present.

Prof. Waugh's address was all the more convincing and conclusive from the fact that he said he was a not a beekeeper, never had been one, and never expected to be. His statement is especially valuable when we remember he is regarded as one of the greatest authorities on fruit culture in the United States.

ONTARIO A GREAT PROVINCE FOR BEES.

On the evening of June 11, Mr. Morley Pettit, general instructor in apicultural work at the Ontario Agricultural College, gave an exceptionally interesting stereopticon address on the subject of Ontario bee culture. His views were unusually instructive. At the close of his address it was apparent that Ontario, Canada, would rank with any State in the Union, if it did not surpass it, in the number of its extensive honey-producers and in the amount of honey annually produced. The conditions in Ontario seem to be exceptionally favorable—so much so that it is extremely doubtful

whether any State in the Union, not even excepting Texas, Colorado, Nevada, or California, can equal it. "And yet," said Mr. Pettit, "not all the available bee territory in the Province is taken up." He referred to some spots in the northern part where the seasons are necessarily short, but where the crops are good. The average Yankee could not help wishing, perhaps, that Ontario were a part of the United States.

FONDANT OR THE NEW BEE CANDY FOR QUEEN-CAGES.

On the morning of the second day Mr. O. F. Fuller, of Blackstone, Mass., gave an address on the subject entitled "Experiments with Bee Foods." Mr. Fuller has for several years past been experimenting with a soft candy that he has made use of as a substitute for the candy now made with honey in our queen-cages. Under present government regulations all honey used in candy must be thoroughly boiled to kill any possible disease germs that may be present. Mr. Fuller has been working on the proposition that it is better to have a candy that uses *no honey*. He presented a letter from the Postoffice Department showing that such a candy will be accepted and welcomed.

The candy Mr. Fuller has been experimenting with is technically known by candy-makers as "fondant." A formula that he has been using with considerable success is, granulated sugar 12 lbs.; glucose, such as the makers of candy use (not the commercial article known as karo or corn syrup), 1½ lbs., water 1¼ quarts, and from one-fourth to one-third of a teaspoonful of cream of tartar. The cream tartar, water, and glucose are put together; and as soon as they begin to boil, the sugar is added. The mixture is then stirred until it reaches the boiling-point, when it is discontinued. As soon as it reaches a temperature of 238 or 240 by a sugar-boiling thermometer made on purpose for the candy-maker, it is then removed from the stove to cool. While the ordinary stirring is discontinued at the boiling-point, Mr. Fuller stirs the mixture just enough and no more after that point is reached to keep the temperature about as uniform as possible. But a general stirring should be avoided. When the candy cools to 120 or 125, it is stirred or beaten until it begins to "cream." As soon as it looks like paste or starch it is ready to turn into the feeders. These are nothing more nor less than little wooden trays with glass slides at the bottom. These are filled with soft candy, and when cold are laid glass side up directly over the cluster of bees as a winter food. He has fed a number of colonies with this food, and found that

* Published by the Orange Judd Co., of New York, at \$1.00.

they wintered perfectly. He has also used it with a great deal of success in queen-cages, and has found that it keeps soft and moist. However, he emphasizes the importance of keeping the candy in a closed vessel, and then taking out a supply as occasion requires. When the candy is placed over a cluster of bees it will necessarily keep moist on account of the natural moisture from the cluster. Dr. Gates brought out the point that the cooking temperature will be somewhat dependent on the day. The greater the degree of humidity, the higher will be the temperature. In a dry atmosphere 236 F. will be high enough, and 238 F. on a moist day. There was a candy-maker present whose name I failed to get, who insisted that cream tartar is not necessary. On this point Mr. Fuller could not say positively; but the candy-maker said that if the candy was too moist it could be stiffened up with a little powdered sugar.

In the following discussion Mr. Fuller stated that 1 lb. of grape sugar equals 1½ lbs. of liquid glucose. In other words, 12 lbs. of granulated sugar to one of grape sugar would make a fondant.

Mr. Fuller referred to the criticism that has been raised over the use of glucose; but he argued that the amount of glucose used is very small in comparison with the amount of granulated sugar. He made the point clear, however, that he did not use glucose because of its cheapness, but because it was the best thing he had ever tried for making a soft candy that would remain soft for months.

FIELD-DAY EXTRACTING.

In the afternoon of the second day there were demonstrations in extracting with a hand-power and a large power extractor and honey-pump, uncapping with a steam-heated knife, and melting the cappings in a capping-melter. To witness these operations the members of the convention passed into the convention in single file and out as each demonstration was made.

SHIPPING BEES IN COMBLESS PACKAGES.

There had been shipped to Dr. Gates sample packages of bees without combs. The bees were on exhibition, and, later on, places in the hives, some on unsealed brood and some on frames of foundation. Dr. Gates is in sympathy with any plan for shipping bees over the country that will eliminate bee disease by the omission of comb. He gave an address on that subject at one of the sessions, which we did not hear.

A NEW OBSERVATORY HIVE.

Mr. Geo. T. Whitten, of the Hartford School of Horticulture, exhibited an obser-

vatory hive that will admit of the examination of any single comb without opening the hive. This looks like an impossibility; but seeing is believing. This will be a great hive to use at schools and colleges and by timid people who would like to watch the bees work without opening the hive. We hope to have an illustration of this in an early issue of GLEANINGS.

THE OLD "LONG IDEA" HIVE REVIVED.

Mr. A. W. Yates, one of the State deputy inspectors, of Hartford, Conn., exhibited a double-walled hive with a capacity, all in one story, of something like 25 frames. It involves the principles of the old Long Idea hive of forty years ago that was so much exploited at the time, but which was finally abandoned. Mr. O. O. Poppleton, of Stuart, Florida, however, continues to use it. As Mr. Poppleton is regarded as one of the best beekeepers in the United States, the "Long Idea" did not wholly die. Mr. Yates argued that his hive, built on that principle, required very little care. In fact, it can be managed on the let-alone principle more nearly than any other hive with which he is acquainted. He thinks that enormous crops of honey could be secured, and at the same time keep down swarming by the system of manipulation of a queen-excluder. We have asked him to illustrate and describe this method in GLEANINGS at some future time.

SOIL FOR GROWING CLOVERS.

One of the addresses that was listened to was one by Prof. W. P. Brooks on the subject of increasing clovers and honey-plants. Prof. Brooks is one of the acknowledged authorities on soils. He explained that clovers will grow anywhere if they get the soil food right. But many soils are deficient in lime; and when lime is supplied, clovers will grow profusely.

A notable feature of the Amherst meeting was a large exhibit room where supplies from many of the manufacturers were on display. There were also to be seen old hives of ancient pattern, curios, and various articles of ingenious and odd invention. This room was well occupied in the between sessions. There was something doing, therefore, at this meeting almost from morning till night.

We respectfully suggest that President Gates arrange for a field meet of the National Beekeepers' Association at some convenient date at Amherst. It has a most complete equipment, and if Dr. Gates should be authorized to get up a field meet at the college it would go down in apicultural history as one of the great conventions in the history of the Association.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

MR. EDITOR, that's a fine write-up of foul-brood legislation, p. 362. Now take up spraying, and handle it the same way some of these days.

ARE there any scales constructed for the apiary, or will any platform-scales stand the weather? [There are no scales specially constructed for the apiary; but practically all the standard instruments all of metal would stand exposure to the weather. As a general proposition scales on the gravity or steelyard principle are not as suitable for outside exposure as a platform spring scale with an enclosed dial.—Ed.]

G. M. DOOLITTLE, you've painted the swarming business very fairly, p. 367, but one thing needs to be added. It looks very pretty on paper to have a swarm with a clipped queen obliged to return and hive itself; only in a large apiary, when swarms issue simultaneously or in close succession, there are entirely too many cases where the swarm, instead of returning to its own hive, heeds the call of a returning or lately returned swarm at some other hive.

D. L. WOODWARD seems to think, p. 213, that the out-apiarist who has an auto should have horses as well. I wonder how many agree with him. [We do not believe it is necessary to own a team. That would be too expensive. But an automobile truck can do a great part of the work. The few times that a team would be required would be more economically handled by a livery. Something, of course, would depend on the roads.—Ed.]

M. R. PINCOT says, *L'Apiculteur*, 160, that brood-comb is never less than 24 millimeters (.945 inch) in thickness. The common thing here is to say it is $\frac{7}{8}$, or .875 inch. That's a difference of more than 1-16 inch. Mr. Editor, please tell us the exact measurement at Medina. [Some years ago we made some quite extensive measurements in our apiary, and the average of all measurements was as near $\frac{7}{8}$ of an inch for worker comb as it was possible to make it.—Ed.]

WESLEY FOSTER seems a little shy as to admitting that it is the proper thing to compensate a beekeeper for his loss from foul brood, p. 365. I don't wonder. Certainly it would never do to allow full compensation so long as there are men who burn down their houses to get the insurance. Indeed, there may well be question whether there should be any compensation at all, unless a man is hit so hard that he becomes

a public charge. If smallpox breaks out in my home I don't get any compensation; and why should I any more if disease breaks out in my apiary?

OTTO DENG, *Deutsche Bzcht.*, 23, gives some interesting figures regarding the development of a vigorous colony. At intervals of ten days, at 10 A. M. he counted the number of bees returning from the field during the space of ten minutes, also how many of them carried pollen. April 1, in ten minutes he counted 318 returning bees; and of these, 94 carried loads of pollen. The other counts were these:

April 10, there were 476 bees, 142 with pollen. April 20, there were 584 bees, 268 with pollen. May 1, there were 782 bees, 281 with pollen. May 10, there were 1045 bees, 367 with pollen. May 20, there were 1462 bees, 418 with pollen. June 1, there were 2364 bees, 624 with pollen. June 5 (twelve days after first drones flew) a swarm of 8 lbs. 6 oz. issued. The per cent of bees carrying pollen at the different dates was respectively as follows: 29.6, 29.8, 45.9, 35.9, 35.1, 28.6, 26.4.

MORE and more beekeepers are getting to think bees should not be left with a space of half an inch, or even an inch, between bottom-bars and hive-floor. I first adopted a bottom-board two inches deep because I wanted the deep space in winter. But in summer bees would build down in so deep a space, so I put in a shallow box upside down to fill up the space in summer. Then I improved on that by using in summer an open rack. Now comes the Junge-Peirce team, p. 308, with a deeper space and with open sides, which ought to be an improvement, as giving still more air. Leon C. Wheeler comes next, p. 314, with exactly my bottom-board, only he has ventilation at sides and back, and has no bottom-rack. The question is, Do the bees never build down in that two-inch space? Leon, if they don't, your bottom-board is a big thing. J. P. Blunk has a deep bottom-board, open at back as well as front; and, if I mistake not, bees never build down in it. In whatever shape it is given, the deep space under bottom-bars is an important factor in helping to prevent the desire to swarm. [We arise here to inquire whether your first sentence states the facts. We would have said, basing the opinion on the correspondence that has passed through our hands, that more and more beekeepers are beginning to accept the deep space under the frames as better than a shallow space.—Ed.]

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

Just now (June 5) we are having a dearth of honey, and a very severe drouth which is checking the clover badly. As blossoms are just beginning to show, naturally we are earnestly hoping for a soaking rain, without which we can not expect to get a crop of honey.

Later.—The rain came.

* * *

Dr. Miller, I want some more light on that first Straw of yours on page 140, March 1. You say that Dr. Phillips "is trying to learn what instruction to give the bees for best wintering in cellars." Please tell him for me that some beekeepers who have cellars too warm, or defective in some other way, would like to know how to "instruct" the bees to keep quiet when they get too noisy.

* * *

In June Notes I said, "The season for fruit bloom is one of the earliest on record;" but now with May just ended I must revise that and say that it was one of the latest as well. Why this paradox? Simply because, just after writing that note in early May, the weather turned cool and stayed cool all through the month. Apple-blossoms were open for three weeks, while last year they lasted but three days. Little nectar was gathered through all this period, however, owing to the chilly weather; but whenever it warmed up a bit, honey came in rapidly.

* * *

Commenting on the fact that we got 600 pounds of honey when melting those cappings that yielded 350 pounds of wax, page 379, June 1, the editor expresses surprise that there was so much honey to that quantity of "drained cappings." Perhaps it would be better to qualify the statement where I say the cappings "were pretty well drained" when the evidence points otherwise. At the east yard they had but one uncapping-box, and it was emptied each morning into the barrel after draining all night. When emptying those barrels I noticed that in the bottoms the cappings were pretty rich in honey, so that explains the more than usual amount obtained. But making all due allowance for that, I was still surprised at the amount obtained.

As to using that honey, just now it is coming in handy in feeding some colonies that are rather short, between fruit bloom and clover. It is heated to the boiling-point with about one-third as much water as honey, and makes an ideal food.

Page 216, April 1, shows two of Mr. Holtermann's helpers taking combs from the hive, one holding the comb and the other sweeping off the bees. If helping in the yard myself, I should prefer to hold the comb myself; for after the bees have been pretty well cleaned off with a vigorous shake that can be acquired only by practice, about two quick strokes of the brush will take off what few bees remain on the comb. I am quite sure that I can do this quicker and easier than with the help of an assistant; *but* I don't object to the other fellow carrying or wheeling the honey into the extracting-house.
